Final report from the Imperial Institute dated June 21, 1928, on *Hydnocarpus* seeds from Ceylon. ANON. Imperial Inst. *Tropical Agr.* (Ceylon) 71, 208-10 (1928).—The seeds and oil of several species of *Hydnocarpus* were examd. to det. their suitability as sources of chaulmoogric and hydnocarpic acids for treatment of leprosy. Analyses of *Hydnocarpus alpina*, *H. octandra* and *H. venenata* seeds gave the following results: kernels 28.5, 69.6 and 62.5%, resp. The kernels contained H_2O 4.3, 3.8 and 4.9, and oil 62.7, 66.7 and 63.7%, resp. The optical rotation of the respective oils in CH_2Cl was $+47.58^\circ$ at 20° , $+54.11^\circ$ at 17° and $+53.47^\circ$ at 21° . The fatty acids gave optical rotations as follows: 50.12° at 18° , 54.03° at 18° and 56.19° at 22° and solidifying points of 39.2° , 48.5° and 47.0° . Treatment of the fatty acids by the method of Power and Barrowcliff indicated the presence of chaulmoogric acid in each oil. Hydnocarpic acid was not definitely detected in any of the 3 oils but may be present in small quantities. Samples of seed from *H. venenata* were sent to the Leprosy Research Lab. at Calcutta. The oil gave the following analysis: oil from seeds by cold expression 24%, acid value 20.5, sapon. value 212.2, I value 89.1, sp. rotation at 20° $+58.4$. Clinical tests of the oil in leprosy cases gave results which do not appear to differ from those obtained with oil from *H. wightiana*.

A. L. M.

A principle easily extracted from *Sphacele parviflora* L. V. HASENFRATZ. *Compt. rend* 187, 903-4(1928).—The plant, which is of the order Labiateae, was collected in the Pacho region, Columbia, at an altitude of 1800 to 2000 m. The leaves are made into cigars, which are smoked by the inhabitants as an alleged prophylactic. Upon aging, a white deposit appears on the cigars. The dried and pulverized leaves on extrn. with steam yielded a waxy product at the rate of about 3 g. per kg. This product was insol. in water but sol. in alc., Et_2O or $CHCl_3$, cryst. needles, m. 105° . Analysis led to the formula $C_{15}H_{24}O$, the same as that of a camphor, ledol, obtained from *Ledum palustre*, order Ericaceae. These 2 substances appear to be identical.

L. W. R.

The stabilization of medicinal plants. FRANCESCO NICOLA. *Giorn. farm. chim.* 77, 357-78(1928).—A survey is given of the plant enzymes and the changes produced by them in the chem. compn. of the active principles of medicinal plants subjected to drying. The methods used for stabilizing the plant material, i. e., for destroying the enzymes without injury to the drugs, are discussed.

G. SCHWOCH

Titration of preparations of the posterior lobe of the hypophysis by means of the

sheep uterus. PAUL TRENDLENBURG. Univ. Berlin. *Arch. expl. Path. Pharm.* 138, 301-5(1928).—With the sheep uterus the results corresponded within 20% to actual values. G. H. S.

Antivenin (Nearctic Crotalidae). JOSIAH C. PRACOCK. *J. Am. Pharm. Assoc.* 17, 750-60(1928).—Methods of collecting venom and production of antivenin by injection into the horse are described. The antivenin is standardized by injection of a mixt. of venom and antivenin into a pigeon's wing. One cc. of antivenin must neutralize 0.002 g. of venom. The serum is antidotal to the venom of the rattlesnake, copperhead and moccasin. It is believed that the antivenin will retain its potency for 10 yrs. L. E. WARREN

Medicinal plants of Florida. ERNST T. STUHR. *J. Am. Pharm. Assoc.* 17, 761-6(1928).—A catalog arranged according to botanical families. L. E. WARREN

Epsom salt of today. EDWARD S. ROSE. *J. Am. Pharm. Assoc.* 17, 771-2(1928).—Twelve specimens of Epsom salt were purchased in drug stores between N. Y. City and San Francisco. Each was subjected to the U. S. P. tests. All were of good quality. One specimen had effloresced somewhat with consequent high assay. L. E. WARREN

Stability of solutions of potassium arsenite. ELIZABETH PICKERING. E. R. Squibb and Sons *J. Am. Pharm. Assoc.* 17, 848-50(1928).—Review of the literature L. E. WARREN

The pharmacopeia of the United States. E. FULLERTON COOK. *J. Am. Pharm. Assoc.* 17, 1078-80(1928).—The status of the researches which are being conducted by or for the Committee of Revision is given. L. E. WARREN

Stability of homatropine hydrobromide solution. PAUL S. PITTINGER AND JOHN C. KRANTZ, JR. Sharp and Dohme. *J. Am. Pharm. Assoc.* 17, 1081-4(1928).—A 1% soln. of homatropine-HBr was prepd. with distd. H₂O and another soln. with NaCl soln. isotonic with the tear. Each soln. was biologically tested by the cat-eye method and they were found to be identical. Each soln. was subdivided into 8 parts and the several fractions were kept under various conditions of storage. Some of the subdivisions were sterilized; others were exposed to ultra-violet light; still others were placed in ampoules and stored. The mydriatic action was not decreased by any of the treatments. Ampoules retained their strength for 9 months. L. E. WARREN

Mercuric iodide determination in tablets. H. O. MORAW. *J. Am. Pharm. Assoc.* 17, 1084-6(1928).—Place a weighed quantity of the powd. tablets, equiv. to 0.25-0.4 g. of HgI₂, in a beaker, add 0.2 g. of lactose and mix with a glass rod. Add sufficient 10% NaOH to make a paste and mix well. Add more NaOH soln. to make about 30 cc. Digest over a low flame for 30-50 min. Dil. to 75 cc. with H₂O and filter the mixt. while hot. Add a slight excess of AgNO₃ soln. and 25 cc. of HNO₃ and boil the mixt. gently until clear. Collect the AgI, dry it and weigh in the usual way. If Cl is present, wash the AgI with dil. NH₄OH soln. The incomplete reduction of HgI₂ in alk. soln. is due to incomplete peptization and occlusion. Thorough mixing of the tablet material with lactose followed by careful manipulation with the alk. soln. insures the complete reduction of the Hg compd. The method is accurate within about 1%. L. E. WARREN

Indian Ephedra species. H. E. READ AND C. T. FENG. Peking Union Med. Coll. *J. Am. Pharm. Assoc.* 17, 1189-92(1928).—Four species of *Ephedra* growing in northern India were examd. for alkaloids and the proportions of ephedrine to total alkaloid detd. *Ephedra intermedia* (dry broken stems) 1.17% alkaloids; 30-40% ephedrine. *E. intermedia* (unbroken stems) 1.14% total alkaloids; 30-40% ephedrine. *E. gerardiana* 1.65-1.70% total alkaloids; 70-80% ephedrine. *E. sinica* 1.32% total alkaloids; 80-85% ephedrine. *E. equisetina* 1.75% total alkaloids; 85-90% ephedrine. The large proportion of pseudoephedrine in *E. intermedia* does not disqualify its use in manufacturing, since it is easily possible to convert one isomer into another up to 50%. L. E. WARREN

The incompatibility of sodium salicylate and sodium bicarbonate mixtures. JOHN C. KRANTZ, JR. Sharp & Dohme, Baltimore, Md. *J. Am. Pharm. Assoc.* 17, 1203-6(1928).—Chemicals free from Fe were selected. A soln. of Na salicylate (about 6%) was prepd. and portions were mixed, resp., with a soln. of (A) NaHCO₃, Na₂CO₃ and NaOH. The mixt. contg. (A) gave a black ppt. in 6 days, that with Na₂CO₃ became brown in 10 days and that with NaOH remained practically colorless after several months. Oxidation is one of the important causes in producing the reaction. Light is without influence. The action of NaHCO₃ solns. upon certain compds. related to salicylic acid, such as Na benzoate and PhOH, was studied. In some there is a slight darkening

after a long time; in others there is no reaction. The reaction is peculiar to *o*-hydroxybenzoic acid.

L. E. WARREN

The alkaloids of *Bocconia frutescens* L. EMERSON R. MILLER. *Ann. Polytech. Inst. J. Am. Pharm. Assoc.* 18, 12-4(1929).—*Bocconia frutescens* L., family Papaveraceae, is found in tropical America. The plant reaches a height of 10-12 ft. Examn. of the bark of the larger specimens showed it to be rich in alkaloids and to contain a red resin. The leaves were studied. At last 4 alkaloids were obtained. Two were identified as γ -homochelidonine and protopine. The others are probably β -homochelidonine and chelerythrine. Because of the large size of the leaves and their high alkaloidal content it is believed that *Bocconia* is probably the best known source of protopine.

L. E. WARREN

Ammonium acetylsalicylate—"ammon-aspirin." NORMAN E. WOLDMAN. *J. Am. Pharm. Assoc.* 18, 14-7(1929).—Acetylsalicylic acid was prepd. by the usual methods and the product neutralized by NH_4OH . The crystals of NH_4 acetylsalicylate were sepd. by centrifugation, washed with H_2O contg. a little NH_4OH and dried. The product is a white, cryst. compd., odorless, sour, decomp. above 70° and non-toxic.

L. E. WARREN

The stability of anesthetic ether. F. W. NITARDY AND M. W. TAPLEY. *Anesthesia and Analgesia* 7, 318-20(1928).—Peroxides do not exist in freshly prepd. anesthetic ether, but develop as a result of subsequent changes in the material when stored in the glass and tin containers now used commercially. An adequate surface of Cu on the interior of the container will prevent this formation of peroxides, but will not remove peroxides from deteriorated ether.

R. C. WILLSON

Industrial ethylation. Manufacture of dionin(MCLANG) 10. Chemical composition and properties of some special kinds of glass (PESHEL, POPOV) 19. Determination of alkalinity of glass for medical ampoules (POPOV, KLYACHKINA) 19. Theory of steam distillation (of essential oils) (RENGROVE) 2. Action of ultra-violet light on ferric citrate solutions (FRY, GERWE) 3. The effect of sunlight on citric acid in the presence of ferric salts (BURT) 3. Oil and fat treatment (Can. pat. 285,879) 27. Unsymmetrical areno compds. (U. S. pat. 1,688,351) 10. Yoghurt (Ger. pat. 470,035) 12. Turkey-red oil substitutes (Fr. pat. 642,392) 27. Condensation products from reaction products of S_2Cl_2 and primary arylamines (U. S. pat. 1,699,432) 10.

Annual Report. Essential Oils, Synthetic Perfumes, etc., 1927. Miltitz near Leipzig: Schimmel & Co. 250 pp. Reviewed in *Am. J. Pharm.* 100, 797(1928).

Chemist and Druggist Diary, 1929. London: Chemist & Druggist, Offices. Reviewed in *Pharm. J.* 121, 602(1928).

Synthetic drugs (anesthetics). CHEMISCHE FABRIK VORM. SANDOZ. Brit. 291,850, March 4, 1927. Salts of *m*-aminobenzoic acid alkyl esters with alkylsulfonic acids are made by interaction of the 2 components in equimol. proportions or by double decompn. of sol salts of *m*-aminobenzoic acid esters such as hydrochlorides, hydrobromides or sulfates, with alkali or alk. earth metal salts of alkylsulfonic acids. The products are sol in water and form solns. which are stable on boiling. Examples are given of the prepn. of salts of the Et, Pr and iso-Bu esters with methane- and ethane-sulfonic acids. The *m*-aminobenzoic acid Pr and iso-Bu esters are made by heating *m*- $\text{O}_2\text{NC}_6\text{H}_4\text{COCl}$ with PrOH and iso-BuOH and reducing the resulting nitrobenzoic acid esters with Fe and H OAc .

Medicinal iron preparation. ALFRED STEPHAN. Ger. 468,424, Feb. 3, 1927. Aq. solns. of iron glycerophosphate contg. sugar are preserved by addn. of benzoic acid.

Medicinal quinine solutions. CHEMISCHE-PHARMAZEUTISCHE A.-G. Brit. 291,565, April 4, 1927. In prepg. solns. of basic quinine in oils by means of terpenes, as described in Brit. 266,209 (C. A. 22, 481), the solvent effect of the terpenes is increased by addn. of fat-sol. alcs. such as octyl alc., decyl alc., benzyl alc., phenethyl alc. and cinnamyl alc. Olive oil, sesame oil, paraffin oil and wool fat may be used and cineole and oil of turpentine are suitable terpenes. Other drugs such as alkaloids may be added.

Medicinal waters. G. H. ORGLMEISTER & CO., VEREINIGTE PRODUKTE UND DERIVATE. Austrian 111,248, June 15, 1928. Solns. having a beneficial effect when used as

beverages or baths are prepd. by carefully burning carbonaceous materials of vegetable origin, such as coal or peat; and extg. the ash with water. Coal rich in Cl and As and contg. more K than Ca is washed before burning.

Medicinal colloidal adsorption of hydrochloric acid. VINCENT A. LAPENTA. U. S. 1,699,596, Jan. 22. An infusion of agar-agar is subjected to steam pressure in an autoclave, HCl is added, and the material is further admixed with siliceous earth contg. tribasic Ca phosphate, to prepare a product suitable for internal administration for liberating HCl in the stomach.

Medicinal product from amniotic fluid. HERBERT L. JOHNSON. U. S. 1,696,958, Jan. 1. A therapeutic compn. suitable for preventing peritonitis and adhesions after surgical operations is prepd. by removing or neutralizing possibly harmful ingredients of amniotic fluid, *e. g.*, by filtration and sterilization of amniotic fluid from cows.

Purified product from amniotic fluid. JASPER P. SCOTT (to Eli Lilly & Co.). U. S. 1,699,479, Jan. 15. A purified and concd. product which is suitable for preventing adhesions after surgical operations comprises a fraction of amniotic fluid sol. in alc. of 70-80% concn. but insol. in alc. of 90-95% concn. and from which the fractions insol. in alc. of less than 70% concn. also have been removed as have also those fractions sol. in alc. of above 95% concn.

Emetine. CHEMISCHE FABRIK VORM. SANDOZ. Brit. 291,088, May 27, 1927. Emetine is produced from cephaeline by methylating with salts of phenyltrimethylammonium hydroxide or with a mixt. of substances forming the quaternary base, among the salts which may be used are the *p*-toluenesulfonate and the hydrochloride. Cf. C. A. 23, 612.

Theobromine. C. H. BOEHRINGER SOHN. Fr. 640,955, Sept. 13, 1927. Theobromine is extd. from substances contg. it such as cacao pods, by means of water, or aq. solns. of alk. earth hydroxides, at ordinary or slightly raised temp., and sepg. the theobromine in known manner.

Organometallic compounds. ALFRED EHRENREICH and RUDOLF HAUSCHKA. Fr. 641,514, Sept. 27, 1927. New substances which have remarkable bactericidal properties and have a great affinity for vegetable fibers, such as wood fiber, are made by reaction of an alk. soln. of Hg salts and KCN with halogenated phenols, cresols or their homologs. The structure is probably Halogen-X-Hg-O-Hg-CN, where X represents a phenol or like nucleus.

Complex antimony compounds. HANS HAHN (to Winthrop Chemical Co.). U. S. 1,688,964, Oct. 23. An antimonyl compd. such as antimonyl pyrocatechol, derived from a polyphenol contg. 2 OH groups in *o*-position to each other, is caused to react with a neutral salt of an aliphatic hydroxy acid such as tartaric or citric acid, *e. g.*,

with Na tartrate, to produce derivs. such as $\text{NaO}_2\text{CCH}(\text{OSb} \begin{array}{c} \diagup \diagdown \\ \diagdown \diagup \end{array} \text{C}_6\text{H}_4)\text{CH}(\text{OH})\text{CO}_2\text{Na}$

which may be used as *therapeutic agents*. Their aq. solns. have no irritating effect and can be sterilized at 100°. They are not pptd. by alkalis but are pptd. by alkali metal sulfides. Cf. C. A. 22, 2812.

Ammonium salt of hydroxyacetylaminophenylarsonic acid. ERNEST FOURNEAU. U. S. 1,697,910, Jan. 8. A compn. comprising water, the NH_4 salt of hydroxyacetylaminophenylarsonic acid and Na_2SO_3 or other alkali salt of sulfurous acid is suitable for dispensing in ampoules.

Lecithin compound. SOC. ANON. POUR L'IND. CHIM. A BÂLE. Swiss 127,256, Dec. 23, 1926. The prepn. of an additive compd. of lecithin and CaCl_2 , from which lecithin of high purity can be prepd., is described.

Lecithin preparation. HANS MARTIN. Austrian 110,850, May 15, 1928. A prepn. of lecithin for diabetic subjects is prepd. by mixing yolk of egg, opened up with alc. in known manner, with dried milk and cacao butter. Other suitable sugar-free addns., such as grated almonds, may be made.

Pyramidone. I. G. FARBENIND. A.-G. Ger. 469,285, April 11, 1923. To prepare pyramidone, 1-phenyl-2,3-dimethyl-4-nitroso-5-pyrazolone is treated with CH_3O or its polymers and a reducing agent such as Zn dust or Fe and mineral or org. acid. Examples are given.

Iodine-substituted benzonitriles having pharmaceutical uses. WALTER SCHOBLE and KURT SCHMIDT (to Chemische Fabrik auf Actien, vorm. E. Schering). U. S. 1,693,055, Nov. 27. Condensation of I-substituted phenol ethers is effected with metal salts of I-substituted hydroxybenzonitriles, without the halogen being split off or the nitrile group being destroyed, by effecting the reaction at temps. of 210-240° in the presence of a catalyst such as Cu bronze ("Naturkupfer C"). Examples are given.

of the production of 4-(4-methoxy-3-iodophenoxy)-3,5-diiodobenzonitrile (m. 154° and readily sol. in ether, CHCl_3 and hot alc. but insol. in ligroin and water), 4-(4-iodo-3-methoxyphenoxy)-3,5-diiodobenzonitrile and an I-substituted nitrile derived from the K salt of the 1-methyl ether of 2-iodohydroquinone and 3,4,5-triiodobenzonitrile. I substituted nitrobenzenes also may be used as starting materials and the products thus derived then subjected to reduction, as with SnCl_2 , and after diazotization boiled with cuprous cyanide.

Solutions of β -tribromoethyl alcohol. I. G. FARBENIND. A.-G. (Karl Schrans and Siegfried Jaeger, inventors). Ger. 469,825, May 10, 1927. The difficulties met with in prepn. of aq. solns. of $\text{CBr}_3\text{CH}_2\text{OH}$ for medical use are avoided if the $\text{CBr}_3\text{CH}_2\text{OH}$ is first treated with HCONH_2 , suitably in amts. of 20–40%, whereby a liquid product readily sol. in H_2O at body temp. is obtained.

Alkyl- and aralkylresorcinolcarboxylic acids. HANS STENZL. U. S. 1,697,332, Jan. 1. Carboxylic acids of the 4-alkyl- and 4-arylalkyl derivs. of 1,3- $\text{C}_6\text{H}_4(\text{OH})_2$ are formed by treating the starting materials with CO_2 in the presence of alkali, *e. g.*, by use of NaHCO_3 . 4-Phenethyl-1,3-dihydroxybenzene yields a carboxylic acid m. (with decompn.) 208°. The 4-*p*-bromophenethyl-1,3-dihydroxybenzene-6-carboxylic acid m. 204°. 4-Heptyl-1,3-dihydroxybenzene-2-carboxylic acid m. 109–10°. These and similar compds. such as 4-benzyl-1,3-dihydroxybenzene-2-carboxylic acid are of relatively low toxicity and are suitable for use as *internal disinfectants* in the treatment of infections of the urogenital system. In usual therapeutic doses they pass through the body unchanged.

Derivatives of quinolinecarboxylic acid. KARL MIESCHER (to Soc. anon. pour l'ind. chim. à Bâle). U. S. 1,688,409, Oct. 23. An acid halide of haloquinolinecarboxylic acid is caused to react with Me_2NH or other N compd. of the general formula $\text{HN}^+\text{R}^+\text{R}^-$ in which R^+ and R^- represent H or a univalent radical, and the haloquinolinecarboxylic amides thus obtained are then caused to react with compds. of the general formula $\text{R}'\text{OH}$ in which R' represents a univalent radical such as Na alcoholate or alk. potash. Compds. the production of which is described or mentioned include 2-chloro-4-quinolinecarboxylic acid dimethylamide (m. 114°) and the corresponding derivs., di-Et (m. 124°), di-Pr (m. 77°), diallyl (m. 104°), diisoamyl, EtPh (m. 126°), mono-Me (m. 143°), monobenzyl (m. 217°) and piperidide (m. 140°); 2-cyclohexyloxy-4-quinolinecarboxylic acid diethylamide (m. 63°); 2-phenoxy-4-quinolinecarboxylic acid diethylamide (m. 112°); 2-diethylaminoethoxy-4-quinolinecarboxylic acid diethylamide (b.p. 665 168–70°); 2-ethoxy-4-quinolinecarboxylic acid amide (m. 205°) and the following derivs., di-Me (m. 69°), di-Et (m. 68°), di-Pr (m. 60°), diallyl (m. 53°), diisoamyl, EtPh (yellowish oil), mono-Et (m. 152°), monobenzyl (m. 166°) and piperidide (m. 90°); 2-methoxy-4-quinolinecarboxylic acid diethylamide (m. 93°); 2-propoxy-4-quinolinecarboxylic acid diethylamide (m. 61°) and the corresponding 2-iso-propoxy compd. (a colorless oil); 2-allyloxy-4-quinolinecarboxylic acid diethylamide (m. 33°); 2-phenethoxy-4-quinolinecarboxylic acid diethylamide (m. 59°); 2-diethylaminoethoxy-4-quinolinecarboxylic acid anilide (m. 122°). These compds. may be used as *therapeutic agents*.

Barbituric acid derivatives. FRITZ HEFTI. Swiss 127,126, Mar. 14, 1927. 5,5-Disubstituted barbituric acids are prepd. by reaction between alkyl halides and dry salts of 5 monosubstituted barbituric acids in presence of a small amt. of an org. base. Examples are given describing the prepn. of phenylethyl- and phenylallylbarbituric acids from the K salt of phenylbarbituric acid and ethyl or allyl bromide, resp., in each case in presence of pyridine.

Stabilizing solutions of alkali salts of substituted barbituric acids. J. D. RIEDEL-ERL. HAN A. G. Ger. 469,395, Jan. 16, 1928. Gelatin, agar, or the like is added to solns. during or after their prepn. *e. g.*, 100 g. Na *sec*-butylbromoallylbarbiturate is dissolved in 1 l. of sterilized gelatin soln. of 10% concn.

5-Hexylsalicylic acid. F. HOFFMANN-LA ROCHE & Co. A.-G. Swiss 127,649, May 17, 1927. The compd. is obtained by treating the Na salt of *p*-hexylphenol with CO_2 . Its m. p. is 86° and it can be used as a disinfectant.

Water-soluble silicic acid-albumin compound. JOHANN ABRAHAM VON WÜLFING. Swiss 127,125, Jan. 27, 1927. Casein, preferably suspended in an org. medium, is treated with Na_2SiO_3 soln. until a sample dissolves in hot water giving a neutral or feebly acid soln. The product is then sepd., dried and ground; it is intended for medical use.

N-Methyl dianisylisatin. F. HOFFMANN-LA ROCHE & Co. A.-G. Swiss 127,128, Oct. 9, 1926. N-Methyl dianisylisatin is prepd. by methylating dianisylisatin. The product melts at 153°. It is of therapeutic value.

2-Styryl-4-amino-6-ethoxyquinoline. I. G. FARBENIND. A.-G. Swiss 127,650, Sept. 7, 1926. The substance is prep'd. by heating 2-styryl-4-carbazido-6-ethoxyquinoline with alc. and sapon. the thus obtained urethan. The m. p. is 212°. The substance is a strong bactericide.

6-Methoxy-8-(α -diethylamino- δ -methylbutyl)aminoquinoline. I. G. FARBENIND. A.-G. Swiss 127,178, Aug. 8, 1925. Addn. to 125,832. 6-Methoxy-8-(α -diethylamino- δ -methylbutyl)aminoquinoline is prep'd. by treating *N*-diethylaminomethylbutyl-2-amino-4-methoxy-1-aminobenzene with glycerol, H_2SO_4 , and H_3AsO_4 . The product boils at 189–90° under 2 mm. pressure. It is of *therapeutic value*. *N*-Diethylamino- δ -methylbutyl-2-amino-4-methoxy-1-aminobenzene may be prep'd. from 2-nitro-4-methoxy-1-acetylaminobenzene by reduction of the NO_2 group, conversion of the amino comp'd. into the *N*-diethylamino- δ -methylbutylamino comp'd. and removal of the Ac group.

Blood coagulant. MORTIMER BYE (to William S. Merrell Co.). U. S. 1,697,162, Jan. 1. A sol., powdered, blood-clotting ext. of body tissue that will dissolve to form a clear, neutral, water-white soln. is obtained by pptg. an aq. saline lung tissue ext. with acid and neutralizing the ppt. with NaOH or other alkali.

Hormones. NAAMLÖÖZE VENNOOTSCHAP ORGANON TOT BEREIDING VAN ORGAN-PREPARATEN OP WETENSCHAPPELIJKE GRONDSLAG. Brit. 291,081, May 28, 1927. Ovarian hormones are obtained from the urine of pregnant women or animals by use of a volatile solvent, evapn. of the solvent, and extn. of the residue with water. Dil. acids or salts or their mixts. may be present in the extn.

Hormones. I. G. FARBENIND. A.-G. Brit. 291,018, May 23, 1927. Two active substances, having opposite effects on the female sexual organs, are obtained from the anterior lobe of the hypophysis by extn. with org. liquids and with aq. solvents, resp. Various details and modifications of procedure are given.

Hormones. SCHERING-KAHLBAUM A.-G. Brit. 291,005, May 23, 1927. Hormones obtained from sexual organs are rendered more active by irradiation with ultra-violet rays. Brit. 291,006 specifies treatment of extracts from animal organs of internal secretion such as placenta with an alk. earth such as $Ca(OH)_2$ in an aq. org. solvent preferably in the presence of an inert adsorbent, such as 40% alc. used together with kaolin, or 50% acetone used with silica gel (in the case of ext. of testicle tissue).

Tube for holding and spraying ethyl chloride. JOSEPH W. BATCHELOR. U. S. 1,698,528, Jan. 8. Structural features.

Tube for dispensing ethyl chloride. HERMANN A. MÜLLER. U. S. 1,697,731, Jan. 1. Structural features.

Increasing the production of serum in the animal body. ADOLF SABELLA. Austrian 111,252, June 15, 1928. Solns. of physiol. salts of 5 to 25 times the concn. of these salts in the animal blood are introduced into the animal intravenously.

Food compositions to be taken percutaneously. KARL STEJSKAL. Austrian 109,714, Jan. 15, 1928. Food compns. to be taken by rubbing into the skin comprise carbohydrates, albumins, decompn. products of these substances or equiv. foodstuffs, singly or in admixt., dissolved or dispersed in emulsions or solns. of fats or oils in hygroscopic media, particularly such as are assimilable by the body. A typical compn. comprises dextrose 30, glycerol 17.5, fat 35 and egg yolk 17.5%. Cf. C. A. 22, 1655.

Extraction of products from vegetable materials. I. G. FARBENIND. A.-G. (Karl Dorschky, inventor). Ger. 469,494, July 15, 1926. The extn. from vegetable materials of water-insol. or difficultly sol. products for medical, cosmetic, or other purposes is effected with an aq. soln. of a sulfonic acid of high cleansing properties, or its salts.

Composition containing isopropanol for cleansing the hair and scalp. CARLETON ELLIS. U. S. 1,700,035, Jan. 22. Isopropanol may be used with other ingredients such as tertiary butanol.

Lavage and degreasing composition. CARLETON ELLIS. U. S. 1,700,036, Jan. 22. A vehicle suitable for use on the skin contains not more than 3% of water and consists mainly of isopropanol with a small quantity of tertiary butanol together with odorous substances.

Cosmetic preparations for baths, etc. S. L. LEICHNER. Brit. 292,042, Jan. 21, 1928. Finely divided rice starch is mixed with carbonates and acids, in dry condition, and with perfumes.

Reducing the nicotine content of finished tobacco goods. GENERAL-DIREKTION DER ÖSTERREICHISCHE TABAKREGIE. Austrian 110,885, May 15, 1928. The dry goods are heated rapidly to above 150° and subjected to a rapid stream of air, dry steam, or other gas preheated to the same temp. Suitable plant is described.

Disinfectant from beechwood tar. HERMANN SUIDA. Austrian 111,381, July 15, 1927. The crude oil obtained by the distn. of beechwood tar over a free fire is fractionally distd. *in vacuo* without preliminary chemical treatment, the fraction passing over at 100–170° under 700–740 mm. vacuum being used as the base of disinfectant compns.

Disinfectant, particularly for preventing or curing foot-and-mouth disease. ADDE VON DER WAL. Ger. 468,579, Feb. 26, 1928. The disinfectant is prepd. by warming $\text{Pb}(\text{OAc})_2$ soln. with PbO in such proportions that a filtrate of sp. gr. about 1.24 is obtained, adding alum to the filtrate, with or without $\text{B}(\text{OH})_3$ and filtering again. The compn. may be improved by addn. of insectifuges such as tincture of eucalyptus, myrrh, or aloes, citronella oil, etc.; it may also be colored and prepd. in ointment form by suitable addns. Examples of suitable proportions are given.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

The activity of various contact substances in the sulfuric acid contact process. I. BERNHARD NEUMANN, HEINZ PANZNER AND ERICH GOEBEL. Tech. Hochschule, Breslau. *Z. Elektrochem.* 34, 696–704 (1928).—An investigation of the catalytic activity of Ag_2VO_4 , V_2O_5 , $\text{Cu}_3(\text{VO}_4)_2$, V_2O_6 , WO_3 and Ag as compared with Pt in the H_2SO_4 contact process. A contact app. is devised in which the SO_2 and air used are so passed through connected tubes that they are dried, mixed, measured (velocity and amt.), contacted with the catalyst placed in a hard-glass tube running through an elec. furnace and the resultant SO_3 is properly absorbed for analysis. The gas mixt. consists of 7% SO_2 , 19.53% O_2 and 73.47% N_2 . Curves of % SO_2 converted into SO_3 against the temps. (up to 700°) are plotted for the various gas velocities (150 and 300 cc./min. usually, occasionally 75, 500 and 750 cc.). The app. is tested with platinized asbestos contg. 7% Pt, the max conversion being 99.5–99.7% at 425°. Conversion curves show a max. of 97% at 150 cc./min. and 450° with asbestos contg. 5% AgVO_4 ; 90% at 150 cc./min. and 512° with pumice stone contg. 33% V_2O_5 ; 91.3% at 150 cc./min. and 512° with $\text{Cu}_3(\text{VO}_4)_2$, V_2O_6 , thus increasing the activity of V_2O_5 only slightly. WO_3 and Ag act very poorly as catalysts in this reaction. The catalytic activity of these agents is below that of Pt in the order given. With increase of gas velocities and temps. the maxima are lowered.

J. BALOZIAN

Gas investigations in the Opl tower system. II. W. HANSEN. *Chem.-Ztg.* 52, 830 2 (1928); cf. *C. A.* 23, 484. —A long series of analytical methods for the examn. of tower gases showed that the procedures satisfactory for chamber H_2SO_4 plants were not applicable, and no certain conclusion was reached as to the best methods to recommend. Absorption of the gas in NaOH solns. and later detn. of the SO_2 gravimetrically and the N_2O_5 by reduction to NH_3 (Dewarda's method) and distn. were the most promising schemes used.

W. C. EBAUGH

Manufacture of aluminum sulfate from clays. I. E. ADADUROV. Kharkov Inst. of Applied Chem. *J. Chem. Ind. (Moscow)* 5, 941–2 (1928).—Clays whose Al_2O_3 is mostly in the form of kaolinite are more easily attacked by H_2SO_4 if preliminarily calcined at 800° rather than at 700°. Clays in which the Al_2O_3 is only about 34% in the form of kaolinite are more sol. in H_2SO_4 after a preliminary calcination at 700° rather than at 800°. The latter clays also require a stronger acid (50% H_2SO_4 instead of 20%) for soln. and give a poorer yield. A certain quantity of Fe always contaminates the $\text{Al}_2(\text{SO}_4)_3$ obtained, but this impurity is less for clays rich in kaolinite than for those whose Al_2O_3 is mostly not in form of kaolinite. To obtain $\text{Al}_2(\text{SO}_4)_3$ almost free from Fe it is advisable to eliminate the latter by chlorination of either crude clays or of $\text{Al}_2(\text{SO}_4)_3$. In treatment of crude clays Fe begins to chlorinate at 300° and is ended at 400° without affecting the Al of clays mixed with charcoal, since the latter does not begin to chlorinate below 500°. Chlorination of $\text{Al}_2(\text{SO}_4)_3$ gives even better results but requires preliminary dehydration and expensive operation, and also a stricter regulation of temp., as $\text{Al}_2(\text{SO}_4)_3$ begins to chlorinate just above 400°. B. N.

Ferrous oxide from iron and magnetite. C. TRAVIS ANDERSON. Bur. Mines, Repts. Investigations, No. 2898 (1928).—New data on the formation of FeO from Fe and Fe_3O_4 indicate that an increase in temp. decreases the % FeO in the product. The comparisons show that the reaction to produce FeO purer than 85% must be carried out at temps. at which the reactants are all in the solid state, and that this is impracticable because of the slowness of reaction under these conditions. The curves

indicate the extent to which the reduction of Fe_2O_3 by Fe takes place in the temp. range from 1350° to 1550° .

T. P. KELLER

Manufacture of red oxide by the Neill process. J. ARTHUR REAVELL. *J. Soc. Chem. Ind.* 47, 347-51T; *Chem. Age* (London) 19, 431-2(1928).— FeSO_4 soln. from steel pickling is nearly neutralized by scrap iron and evapd. in a spray drier. Solid FeSO_4 is roasted in rotary kiln to pigment, Fe_2O_3 . Flue gas from the kiln is used in the spray drier.

G. B. TAYLOR

Manufacture of potassium chloride from Solikamsk sylvite. II. F. F. WOLF AND V. S. YATLOV. *J. Chem. Ind.* (Moscow) 5, 909-15(1928); cf. C. A. 22, 4207.—Hot solns. of av. Solikamsk sylvite samples have approx. the same compn. as solns. of mixts. of pure KCl and NaCl. At $90-92^\circ$ sylvite solns. contain 26.91 g. NaCl instead of the theoretical 26.35 g. NaCl at 90° , per 100 g. H_2O and 32.25 g. KCl. The equil. of these solns. is reached within 30 min. After these hot solns. are crystd. by cooling to $18-22^\circ$ the mother liquors contain 15.7 g. KCl per l. If crystn. of the hot solns. is done without previous settling of mech. admixts., chiefly clays, gypsum and Fe_2O_3 , and without stirring, by mere standing at room temp. for 24 hrs., followed by filtration *in vacuo* and drying in an oven at $100-105^\circ$, the crystals contain about 90% KCl. If suspended mech. impurities are sepd. from the hot solns. by settling and decantation, then the solns. artificially cooled and stirred, the crystals contain 98% KCl and 2% NaCl. The presence of 2% NaCl in the crystals is chiefly because the latter, after being drained *in vacuo* or by centrifuging, are still contaminated by 5% of the mother liquors which, on evapn. in the oven, leave a residue rich in NaCl. It is not necessary to wash the crystals on the filter until the mother liquors, which have been used over and over again, become enriched by MgCl_2 and thus contribute to crystn. of larger amts. of NaCl. In the latter case the crystals are thoroughly drained on a Büchner funnel, moistened with H_2O and after standing a few minutes are drained again. CaSO_4 , always present in sylvites, cannot sep. with KCl under the conditions of crystn.

BERNARD NELSON

Manufacture of manganates and permanganates. E. GRAY. *Rev. chim. ind.* 37, 214-7, 318-20, 349-54(1928).—A review of processes.

P. THOMASSET

Activated carbon: Some industrial applications. J. T. STRACHAN. *Chemistry and Industry* 47, 1203-14(1928).—Different types of active C are described, together with their uses in gas masks, recovery of vapors, bleaching oils and fats, purifying chemicals and decolorizing sugar.

G. B. TAYLOR

Carbon black. A study of its volatile constituents. C. R. JOHNSON. *Ind. Eng. Chem.* 20, 904-8(1928).—Because of the discovery of important relationships between volatile matter and reinforcing properties of blacks when used in rubber the volatile constituents were studied. The rates of evolution of gas from C black with variation of time, temp. and pressure were detd. Complete analyses were made of 5 types of C black by org. combustion of the original sample, org. combustion of the sample after the gases have been removed, detn. of the loss in wt. due to gases removed, analyses of the gases removed and finally a complete accounting, or balance, of the C in the steps considered. In an attempt to supply some missing information not revealed by the foregoing some special gas analyses under varying conditions were made. The relationship between the amt. and compn. of volatile matter evolved from C blacks and the properties imparted to vulcanized rubber when compounded with these blacks has been studied. Lab. methods are described in detail. Temp. rises encountered in rubber compounding and the effect of C black discussed.

C. L. MANTELL

Survey of the important kinds of plastic masses. F. SCHMIDT. *Kolloid-Z.* 46, 324-9(1928).—A short survey of the important plastic masses, raw materials used in production, methods of production, uses and methods of application, properties and possibilities. General divisions are cellulose derivs., condensation products and casein derivs.

L. F. MAREK

Dyeworks ferrocyanides from waste. E. T. ELLIS. *Dyer, Calico Printer* 61, 18-9(1929).—Such wastes as spent bog iron ore from the manuf. of gas, brewer's yeast, horn dust from knife-handle factories, leather dust, skin scraps and slaughterhouse refuse may be used for the production of certain ferro- and ferricyanides.

RUBY K. WORNER

Etching stereotype plates. K. SCHUCH. *Chem.-Ztg.* 52, 829-30(1928).—A general description of the methods used in prepg. etchings and half-tones with Zn (using HCl of varying concns.), brass (employing FeCl_3) and Cu (with HNO_3 and KClO_3).

W. C. EBAUGH

Carbon dioxide foam as a fire-extinguishing material. J. BRANDL. *Kolloid-Z.* 46, 145-8(1928).—The cost and phys. properties of a no. of fire-extinguishing materials

are tabulated and the characteristics of the different types of app. in use for generating CO_2 foam are discussed.

J. G. McNALLY

"Acid-proof" packing for absorption towers (BUTCHER) 1. Potash and borax from Searles Lake (TREFLER) 1. A spectroscopic analysis of caliche (BANCHELIN) 3. Recovery of caustic soda (Fr. pat. 641,901) 23. Removing S compounds from gases (Fr. pat. 641,695) 21. Recovery of H_2SO_4 (Fr. pat. 641,460) 21. Apparatus for obtaining C from peat and sawdust (Russ. pat. 3809) 21. Utilizing gases containing N, H and CO_2 (U. S. pat. 1,698,722) 13. Purifying gases (U. S. pat. 1,698,718) 13.

Arsenic acid. FRITZ ULLMANN and GERT TREWENDT (to J. Michael & Co.). U. S. 1,699,823, Jan. 22. A soln. comprising As_2O_3 10 and an oxidizing agent such as NaClO_2 4 parts is heated to about the b. p. and a small quantity of acid such as HCl is added. Cf. C. A. 22, 3269.

Chromic acid. R. SCHUSTER. Brit. 291,249, June 23, 1927. A solid chromic acid prepn. sol. in water is obtained by evapg. a mixt. of CrO_3 or Na or K chromate or dichromate, H_2SO_4 , Na or K silicate or their mixt. and water until the gelatinous mass first obtained becomes cryst. A special order of admixt. is preferred and described.

Phosphoric acid. Édouard Urbain (to Urbain Corp.). U. S. 1,698,484. Jan. 8. Gases produced by burning P are brought into contact with dil. H_3PO_4 previously formed in the cycle of operations, so that the acid is concd. and the gases are mixed with steam and the mixt. of gases and steam formed is passed through a heat exchanger so that heat is given up by the gases to previously formed H_3PO_4 ; the mixt. of gases and steam is converted into liquid H_3PO_4 in the presence of a catalyzer such as coke and the resulting dil. acid is further concd. in the cycle of operations as described. An app. is described.

Water gas, phosphoric acid and molten cement. Édouard Urbain. Fr. 639,412, Jan. 30, 1927. See Brit. 280,763 (C. A. 22, 3269).

Sulfuric acid. WILHELM A. BODAMER and OSCAR ÉMILE RAMUZ. Fr. 641,711, Oct. 1, 1927. Part of the gas is drawn off from the top of the Glover tower and injected into the stream of gas entering at the base, thus producing a regular flow of gas.

Simultaneous production of contact sulfuric acid and hot combustion gases with high sulfur dioxide content. C. PEAUL. Ger. 466,812, Dec. 22, 1926. Combustion gases from the vertical pyrite burners are divided. One part, taken off further from the end of the burner, is passed to a chamber unit or to a sulfite liquor app. The other part goes through a contact app. and an absorption system. The gases from this are led back through the burner entering at a point above the fresh air which is preheated by passage through a heat exchanger in which the pyrite residues give up their heat and absorbed S contg. gases. The gases led off first are richer in SO_2 and poorer in O than the gases taken off below.

Sulfuric anhydride. THE SELDEN CO. Fr. 641,619, Sept. 28, 1927. A gaseous mixt. of SO_2 and O is caused to pass at a high temp. over a catalyst which contains active zeolites which are the products of reaction of a silicate with at least one metallate and at least one metallic salt. In an example, a mixt. of V_2O_5 and WO_3 in KOH soln. is stirred with cellite or ground quartz or diatomaceous earth. The mixt. is heated and made acid with H_2SO_4 and the ppt. is dried and ground and mixed with a soln. of K_2SO_4 and KAlO_2 and the product formed into pieces of convenient size. Other examples are given.

Sulfur trioxide from a gas mixture containing hydrogen sulfide. FRIEDRICH SUMERS A. G. and HANS BÄHR. Ger. 451,530, April 13, 1928. SO_3 is obtained by the catalytic oxidation of H_2S in gas mixts. at temps. slightly above 200° . The catalyst contains at least one S-binding metal such as Fe, Ni or Cu and one metal serving as an oxygen carrier such as W, V or Cr. The metals may be in the elementary form as oxides or as salts and the catalyst may be heated, preferably by electricity. The gas mixt. may be distn. or generator gases and may contain ammonia.

Removing dissolved silicic acid from aqueous liquids. A. ROSENHEIM. Brit. 291,435, June 4, 1927. To remove dissolved silicic acid from liquids such as water or aq. salt solns., the liquid is filtered through or otherwise brought into contact with gels (such as those of ferric oxide or hydroxide, chromic oxide or hydroxide or of oxides or hydroxides of elements of the third group of the periodic system or of Ce or other rare earths) which are capable of forming insol. or only slightly sol. silicic acid adsorption compds. Alkali-contg. gels of the specified substances, as described in Brit. 286,307 (C. A. 23, 228), may be used and the water thereby also softened and freed from Fe

and Mn. The gels may be regenerated with alkalis, substances of alk. reaction or substances which by hydrolysis yield alkalis.

White titanic acid. I. G. FARBENIND. A.-G. Fr. 641,712, Oct. 1, 1927. Reducing agents such as SO_2 or its salts which cannot transform quadrivalent Ti into tervalent Ti are used for the production of white titanic acid, and in such a concn. as to correspond not only with all the tervalent Fe present but with all the other oxidants present. During the subsequent washing reoxidation of the Fe is prevented.

Vanadic acid. THE SELDEN CO. Fr. 642,362, Sept. 30, 1927. Vanadic acid is purified by treating a crude vanadate soln. with oxidizing agents sufficient to transform the impurities into easily separable substances, and convert the V into the quinquevalent state. A part of the oxidation may be carried out in an alk. soln. and part in an acid soln.

Carbon dioxide. ERNEST W. GEERE. Fr. 641,706, Oct. 1, 1927. See Brit. 276,146 (C. A. 22, 2444).

Ammonia from nitrogen and electrically generated hydrogen. HANS RICHLEER. Swiss 127,519, Oct. 30, 1925. The N is led to the cathode of a specially designed elec. cell to permit it to combine with the nascent H.

Ammonia synthesis, etc. H. HARTER. Brit. 201,253, July 4, 1927. In exothermic catalytic processes such as NH_3 synthesis or oxidation of NH_3 to produce HNO_3 , the gas supply pipe is subdivided into several branches and the outlet openings from it are distributed uniformly along the length of the catalytic tube. The gases may be introduced under pressure and expanded to effect cooling if desired and pure O may be used in producing HNO_3 . An app. is described.

Ammonia separator from crude ammonia water. V. V. PAPKOV. Russ. 4237, Dec. 31, 1927. Mech. features.

Separation of alkali salts. JOHANN A. VON WÜLFING. Fr. 641,244, May 27, 1927. K salts of different acids or Na salts of different acids are sepd. by adding NH_3 to their soln. A sepn. of salts from solns. which contain mixts. of K or Na and NH_3 salts of inorg. acids is also described by adding NH_3 .

Alkali metal cyanide. HERMAN B. KIPPER. U. S. 1,697,529, Jan. 1. Reactive material such as Na_2CO_3 , C and Fe is placed in a closed receptacle in which it is subjected to continuous beating and stirring with great rapidity and maintained in finely divided and disseminated condition; the inner walls of the receptacle are also subjected to a slow scraping to keep them free from the material and the material is continuously subjected to the action of highly heated reactive gases such as producer gas contg. N and CO to effect cyanide production. An app. is described.

Alkali metal cyanide. HERMAN B. KIPPER. U. S. 1,699,362, Jan. 15. In effecting reaction at high temps. between gas mixts. contg. N and a mixt. contg. Na_2CO_3 , C and a Mn Fe ore, reaction is first effected in an insulated receptacle and further action of N-contg. gas on the products is then effected in an externally heated receptacle. An app. is described.

Alkali metal nitrates. WILHELM WILD and CHRISTOPH BECK (to I. G. Farbenind. A.-G.). U. S. 1,699,643, Jan. 22. A soln. of alkali metal chloride is treated with a mixt. contg. N oxides and O, under superatm. pressure, the pressure is released after the oxidized N oxides are absorbed and sufficient of the alkali metal chloride is added that the alkali metal nitrate formed is deposited without evapn. of the soln. U. S. 1,699,644 specifies forming alkali metal nitrates from alkali metal chlorides and HNO_3 and freeing the resulting gas mixt. contg. N oxides and HCl from the N oxides by treatment with H_2SO_4 under superatm. pressure. Cf. C. A. 22, 2815.

Alkali metal titanate. LONNIE W. RYAN (to Titanium Pigment Co.). U. S. 1,697,929, Jan. 8. A calcined product of 2.3-2.9 sp. gr., in the form of a fine, minutely cryst. powder, slightly hygroscopic, white and contg. a preponderance of TiO_2 and sol. in org. and in dil. inorg. acids, is obtained by heating an alkali metatitanate to a temp. below the m. p. It is suitable for use in making various other Ti compds.

Carbonates or oxides of alkaline earth metals. RENÉ DALOZE. Fr. 641,013, Sept. 15, 1927. Crude alk. earth oxides are treated with sugar to form the sucrate, Fe is pptd., the soln. filtered and the alk. earth carbonates are pptd. with CO_2 , giving a very pure product.

Purifying salt and recovering by-products. VICTOR YNGVE. U. S. 1,697,336, Jan. 1. A brine is treated with an excess of NaOH, pptd. hydroxides such as those of Ca and Mg are removed, the purified brine is evapd., salt is sepd. from it, and the mother liquor is used, with removal of Na_2SO_4 , for treating more brine in a cyclic process, and the pptd. salt is washed with a neutral brine. Cf. C. A. 22, 396.

Anhydrous metal chlorides. WILLIAM F. DOWNS. U. S. 1,699,220, Jan. 15. A

metal oxide such as Al_2O_3 is mixed with a soln. of molasses or other suitable residual C-yielding org. compd. in such proportions as to give the required ratio of C to the oxide used, the solvent is evapd. and the residual mass is charred and the solid material is fed into a revolving reaction chamber against a regulated current of hot Cl_2 ; the temp. of the chamber is maintained by external heating and the metal chloride formed is condensed from the evolved gases.

Metal sulfides. K. BRODOWSKI. Brit. 290,986, May 21, 1927. Metals such as Cu, Fe or Pb and S are heated together under pressure in the absence of O and the reaction mass is forced into molds during the heat treatment. The molded blocks obtained are suitable for use as rectifiers or in the production of thermocouples.

Metallic nitrogen compounds. ROBERT GOLDSCHMIDT and SYLVAIN COULIER. Fr. 641,156, Sept. 20, 1927. Cyanides, cyanamides or nitriles are obtained by mixing compds. of alkali metals with peat, drying, carbonizing and treating with N or gaseous N compds. The residual C may be added to the next charge or used as active C for other purposes. A catalyst such as Fe oxide may be added.

Metallic nitrogen compounds. ROBERT GOLDSCHMIDT and SYLVAIN COULIER. Fr. 642,338, Sept. 20, 1927. N or gaseous N compds. such as NH_3 are caused to react on mixts. of activated C and an alkali, alk. earth or earth compd. at a high temp. The C may be activated during the reaction by the addn. of activating agents such as chlorides or oxides of Zn or Mg or phosphates. The mixt. of activated C and metal compd. may be produced by carbonizing a mixt. of the metal compd. and a carbonaceous material and one of the above activating agents.

Cyanogen chloride. I. G. FARBENIND. A.-G. Fr. 642,548, Oct. 16, 1927. CNCl is produced by treating cyanides with Cl hydrate with or without indifferent solvents. The prepn. of the hydrate and its transformation may be carried out in the presence of NaCl or other salts sol. in water. In an example Cl is introduced into a soln. of NaCl in water cooled to 0° in a tightly closed vessel. A soln. of NaCN is run in, the temp. being kept below 8° ; the yield is about 90%.

Alumina. I. G. FARBENIND. A.-G. Fr. 641,623, Sept. 28, 1927. Alumina is extd. from clay, bauxite, etc., with acid, the level of which is maintained above the material treated and the flow of acid, is regulated in such a way as to reach a temp. above 105° in the reaction zone, increasing from the top to the bottom of the charge.

Alumina. ELEKTIZITATSWERK LONZA. Fr. 641,805, Oct. 4, 1927. In the production of Al_2O_3 from bauxite, etc., electrothermally by the addn. of a magnetic metal or compd., the latter is added at the end of the charging period, followed by the addn. of other reducing means such as C, to obtain an even distribution throughout the mass. The Fe may be added in the form of aluminous substances obtained by dissolving primary aluminous substances in HCl , sepg. the soln., evapg. and decompg. the salts by heat. Cf. C. A. 23, 938.

Alumina. ELEKTIZITATSWERK LONZA. Fr. 641,692, Sept. 30, 1927. In the electrothermal prepn. of Al_2O_3 from bauxite, etc., using reducing agents such as C, the initial charge contains less C than is necessary for the reduction of the impurities, and the proportion is afterwards increased to the theoretical amt. and finally an excess is introduced. Towards the end of the charge or after it a heavy metal, preferably Fe or compds. thereof, is added with the C.

Aluminum chloride. CLAUDE G. MINER. U. S. 1,698,238, Jan. 8. Aluminous material such as bauxite or alunite residue is reacted upon with HCl in the presence of C, at a temp. of at least about 1500° .

Aluminum chloride. RENE DE M. TAVREAU and CYRIL B. TYGERT (to Texas Co.). U. S. 1,698,324, Jan. 8. Al ore such as bauxite is dehydrated before being treated with a chloridizing gas, by passing into the ore a stream of hot gas obtained from treating another quantity of Al ore with chloridizing gas. An app. is described.

Aluminum hydroxide. AKTIESELSKAPET NORSK ALUMINIUM CO. Swiss 127,248, May 19, 1926. $\text{Al}(\text{OH})_3$ contg. comparatively little SiO_2 is prepd. from slag or like material contg. compds. of Al and Ca by treating the material with an alkali carbonate soln. contg. an amt. of alkali hydroxide slightly in excess of that required to dissolve the Al_2O_3 , and pptg. $\text{Al}(\text{OH})_3$ from the soln. The extg. soln. may contain also some $\text{Al}(\text{ONa})_3$.

Barium aluminate. RHENANIA-KUNHEIM, VEREIN CHEM. FABRIKEN. AKT.-GES. Fr. 642,291, July 22, 1927. BaSO_4 and aluminous substances are heated to temps. above 1100° in the presence of steam in a neutral or oxidizing atm. to form Ba aluminate.

Barium carbonate from barium silicate. CAMILLE DEGUIDE. U. S. 1,697,722, Jan. 1. Ba silicates contg. silica are ground with water and treated with CO_2 and the

BaCO₃ produced is sepd. from gelatinous silica set free (suitably by use of caustic alkali).

Cooling crude barium sulfide. FIRMA G. POLYSIUS. Ger. 468,390, May 19, 1926. Crude BaS and similar substances are cooled directly in the revolving furnace which is uninsulated and prolonged at the cooling end.

Copper sulfate from industrial liquors and residues. J. P. BEMBERG A.-G. Brit. 291,380, May 31, 1927. Wash liquors and ppts. such as are obtained in the manuf. of "cuprammonium silk" are treated with H₂SO₄ to form CuSO₄ and to carbonize any org. matter which may be present. The CuSO₄ is recovered for further use after heating and sepn. of C formed.

Agglomerating calcium cyanamide. SOC. D'ÉTUDES CHIM. POUR L'INDUSTRIE. Swiss 127,455, May 3, 1927. Addn. to 117,362. In agglomerating CaCN₂ by treating it with a fused bat'l of an acid K salt, the salt is produced *in situ*. For example, a mixt. of KCl and CaCN₂ may be treated with H₂SO₄ or H₃PO₄ in the amt. required to give KHSO₄ or KH₂PO₄.

Dicalcium phosphate and ammonium sulfate. JACOB F. C. HAGENS, LUDWIG ROSENSTEIN and WILHELM HIRSCHKIND (to Barrett Co.). U. S. 1,699,393, Jan. 15. A mixt. of H₃PO₄ and CaSO₄ is treated with NH₃ to produce di-Ca phosphate and (NH₄)₂SO₄.

Potassium silicate. GEORGES ROUYER. Fr. 641,174, Sept. 20, 1927. K₂SiO₃ is stabilized by the addn. of about 35 parts of pure, preferably distd., water to 65 of K₂SiO₃. When so treated the silicate may be readily mixed with paint powders, etc.

Acid sodium pyrophosphate. JOHN N. CAROTHERS and CHARLES F. BOOTH (to Federal Phosphorus Co.). U. S. 1,699,093, Jan. 15. An alkali metal compd. such as Na₂CO₃ is added to H₃PO₄ until neutral to methyl orange indicator, acid Na orthophosphate is crystd. from the soln., the crystals are freed from adhering mother liquor and they are then converted into acid Na pyrophosphate, as by heating to about 240°.

Sodium sulfide. BENJAMIN ROOS (one-half to Roessler & Hasslacher Chemical Co.). U. S. 1,699,377, Jan. 15. Na sulfide is prepd. in the form of substantially spherical pellets which are suitable for shipment and readily dissolve.

Sodium sulfate and hydrochloric acid. HERMAN B. KIPPER. U. S. 1,697,399, Jan. 1. In effecting reaction between NaCl and H₂SO₄ or NaHSO₄, the reacting materials are ground and mixed in a reaction vessel such as a heated cylinder by rapidly moving agitating devices and caking of the material is prevented by more slowly moving devices.

Sodium aluminate. ALUMINUM COMPANY OF AMERICA. Swiss 127,249, Dec. 10, 1926. In the manuf. of a product contg. Al(ONa)₃ by sintering together aluminous materials and Na₂CO₃, the necessary fuel is intimately mixed with the reaction mixt., which is then spread out in uniform layers. The fuel is ignited at a surface of the mixt. and rapidly burnt. The mixt. may be damped to prevent loss as dust. Suitable plant is described.

Complex silver cyanide compounds. C. H. BOEHRINGER SOHN. Ger. 468,808, Feb. 14, 1925. Argentocyanides and chlorates of ammonium, alkali or alkaline earth metals or Mg react with one another in the presence of solvents and the double salts formed are sepd. by careful evapn. or pptn. with org. liquids such as (CH₃)₂CO, Et₂O, etc. The reaction may also be accomplished by fusing the components together.

Activation of silica. I. G. FARBENIND. A.-G. (Wolf Johannes Müller and Hans Carstens, inventors). Ger. 467,464, Dec. 23, 1925. Gelatinous silica is dried until a solid mesh work results. The product is then dried in a rotating furnace.

Titanium compounds from ores. I. G. FARBENIND. A. G. Brit. 290,174, May 6, 1927. See Can. 285,355 (C. A. 23, 673).

Titanium oxide from titaniferous iron ores. CARL R. WHITTEMORE. U. S. 1,699,173, Jan. 15. The Fe content of the ore is reduced to sponge iron without fusion or sintering and after cooling in a non-oxidizing atm. the sponge and Ti content are sepd. from the non-magnetic portion, the treated ore is dissolved with a solvent such as 10% H₂SO₄ soln. and the residue is sepd and heated to about 250° with an acid such as H₂SO₄ in a digester, to form Ti salts; the disintegrated mass is lixiviated with cold water and the soln. is hydrolyzed to ppt. Ti hydroxide, which is sepd. and calcined.

Production of zinc compounds. NAPOLEON A. LAURY. Can. 285,834, Dec. 25, 1928. ZnCO₃ is produced by heating roasted Zn ore to 180° F. in a 20% aq. soln. of (NH₄)₂SO₄, then sepg. out the clear soln., and then satg. the clear soln. with CO₂ at a pressure of 20 lb.

Zinc oxide. JAMES A. SINGMASTER, FRANK G. BREYER and EARL H. BUNCE (to the New Jersey Zinc Co.). Can. 285,734, Dec. 18, 1928. An agglomerated or bri-

quitted charge (with sulfite waste liquor as a binder) of zinciferous material and carbonaceous reducing agent is externally heated in an appropriate chamber, under substantially complete reducing conditions, to a sufficiently high temp. (1200° to 1300°) to reduce the compds. of Zn and volatilize the resulting Zn. The Zn vapor so formed is then conducted into an appropriate oxidizing environment, and the resulting ZnO product collected. Cf. C. A. 22, 1219.

Zirconium compounds. RHENANIA-KUNHEIM VEREIN CHEM. FABRIKEN AKT.-GES. Fr. 642,568, Oct. 19, 1927. See U. S. 1,681,195 (C. A. 22, 3745).

Apparatus for refining "raw" carbon disulfide. PHILIPP SIEDLER and EUGEN SCHULTE (to I. G. Farbenind. A.-G.). U. S. 1,699,255, Jan. 15. Two similar columns are provided with reflux condensers and with boilers, the second of which surrounds the bottom end of the first column; a device for condensing the purified CS₂ is arranged at the level of the reflux condensers and a low-temp. condenser is arranged above the reflux condensers.

Separation of borax and sodium sulfate. CHEMISCHE FABRIKEN OKER UND BRAUNSCHWEIG A.-G. Ger. 468,756, Mar. 17, 1928. Borax is separated from Na₂SO₄ by conversion to an easily soluble sodium borate, *e. g.*, to sodium metaborate by addition of NaOH or to sodium decaborate by addition of boric acid and filtering from the sodium sulfate which remains undissolved.

Baryta. RHENANIA KUNHEIM VEREIN CHEMISCHER FABRIKEN A.-G. Fr. 641,551, Aug. 3, 1927. Crystals of Ba(OH)₂·8H₂O are obtained by treating silicates of Ba with water under pressure above 100° or with a soln. of baryta.

Green corundum. ANTON KRATKY. Austrian 110,676. April 15, 1928. Addn. to 108,704. The method of Austrian 108,704 (C. A. 22, 4213) is modified by including in the initial mixt. very small amts. of La₂O₃ alone or mixed with oxides of Ca, Mg, Sc, Yt, Gd, and Yb. Suitable initial mixts. comprise, in parts, Al₂O₃ 1000, ZnO 40 and CoO 20 with (1) La₂O₃ 1.2 or (2) La₂O₃ 0.6, Yt₂O₃ 0.3, and MgO 0.3.

Hydrogen. JOHN S. BEEKLEY (to The Lazote, Inc.). Can. 284,584, Nov. 8, 1928. H is manufd. by subjecting a S-contg. mixt. of steam and CO under a pressure higher than atm. to the action of a magnesium chromate catalyst. Cf. C. A. 23, 677.

Hydrogen. ROGER WILLIAMS (to The Lazote, Inc.). Can. 284,585, Nov. 8, 1928. H is prepd. by passing a mixt. of steam and CO over a briquetted Cr oxide gel catalyst at 300° to 700°. Cf. C. A. 23, 677.

Hydrogen. I. G. FARBENIND. A.-G. Swiss 127,030, Mar. 8, 1927. In the manuf. of H from hydrocarbons and steam, the catalyst employed contains at least one metal, or compd. of a metal, of the iron group and at least one other metal or metal compd., preferably a metal forming a difficultly reducible oxide or a compd. of such a metal. In the example, the catalyst is prepd. from a soln. contg. Ni(NO₃)₂, Al(NO₃)₃, and Mg(NO₃)₂ by adding K₂CO₃ soln., filtering, mixing the ppt. with KNO₃ soln., drying, and reducing in H at 350°. Over the catalyst so obtained is passed a mixt. of CH₄ (1 vol.) and steam (6.2 vols.) at 430–650°. The process may be conducted in stages with sepn. of CO₂ between the stages.

Hydrogen from water gas, etc. SOCIETÀ ANON. BREVETTI CICALI. Brit. 291,409, June 1, 1927. To obtain H, free from CO and CH₄, from gaseous mixts. such as water gas, coke-furnace gas and the like which also contain N, the gaseous mixt. is preliminarily purified to remove CO₂, SO₂, H₂S, water and other deleterious gases and is then compressed and cooled and washed with liquid N which removes part of the CO which is liquefied and falls to the bottom of the column used. After further cooling and scrubbing with liquid N and then with a mixt. of liquid H and gaseous H to remove all remaining CO the H is evapd. and recovered. An app. is described.

Hydrogen from methane hydrocarbons and steam. I. G. FARBENIND. A.-G. Brit. 291,244, June 18, 1927. In the catalytic production of H such as that from a mixt. of CH₄ with 5–7 times the theoretical quantity of steam in successive stages (such as with alternate use of a Ni catalyst and cerous oxide in 4 stages), the CO₂ is sepd. from the reaction mixt. by absorption at such high temps. that condensation of steam does not occur.

-nitrogen mixture

Phosphorus. I. G. FARBENIND. A.-G. Swiss 127,246, Jan. 19, 1927. Crude phosphates and reducing substances are heated with sufficient Al_2O_3 to give a *cement-like by-product* contg. Ca aluminate.

Separation of phosphorus from gases. I. G. FARBENIND. A.-G. Swiss 127,247, Apr. 4, 1927. The P mist produced when the temp. of the mixt. is lowered below the dew point is sprayed with rapidly moving liquid drops. Suitably, two washers are arranged in series, one being supplied with water at a temp. slightly above the m. p. of phosphorus and the other with water at a lower temp.

Phosphorus and ferrosilicon. I. G. FARBENIND. A.-G. Brit. 290,971, May 21, 1927. P may be obtained from ferro-P by reaction (suitably in an elec. furnace) with substances such as S or Si which will combine with the Fe. Removal of the P vapor for condensation may be facilitated by introducing inert gases.

Concentrating sulfur. EDWARD H. NUTTER and JOHN W. LITTLEFORD (to Minerals Separation North American Corp.). U. S. 1,697,402, Jan. 1. S-contg. material such as Wyoming ore is heated to cause the particles of S to unite, ground to a size suitable for froth-flotation sepn., agitated with a suitable aq. liquid (which may contain pine oil) to produce a S-bearing froth and the froth is sepd.

Apparatus for the sublimation and distillation of sulfur. LUDOVIC KOCH. Fr. 641,946, Mar. 17, 1927.

Dissociating sulfur vapor. I. G. FARBENIND. A.-G. (Philipp Siedler and Eugen Schulte, inventors). Ger. 468,506, Oct. 13, 1927. SiC is used for coating the vessels contg. the heating elements by which S is heated to a temp. at which S_8 dissociates into S_4 or S_2 mols.

Making granulated aluminum for the thermite process. CITY OF MOSCOW. Russ. 4651, Feb. 29, 1928.

Pure carbon. DANIEL GARDNER. Fr. 641,908, Mar. 15, 1927. A pure C is obtained by carbonizing wood or other material at a temp. not above 300° reducing this charcoal to a fine powder and treating with HNO_3 , preferably in the presence of H_2SO_4 , washing with water, treating with a mixt. of HNO_3 and HCl at $75-80^\circ$, washing and treating with an alk. soln. and again washing. The C may be finally heated in a neutral gas to $1000-1300^\circ$. The treatment with alkali may be replaced by a fusion treatment with NaHSO_4 or KHSO_4 , followed by washing and a treatment with an acid soln.

Active carbon. NAAMLIOOZE VENNOOTSCHAP ALGEMEENE NORIT MAATSCHAPPIJ. Fr. 642,262, Oct. 14, 1927. See Brit. 279,104 (C. A. 22, 2817).

Activated carbon. NAAMLIOOZE VENNOOTSCHAP ALGEMEENE NORIT MAATSCHAPPIJ. Brit. 291,725, Oct. 16, 1926. For supplemental activation or reactivation of activated C, the material is treated with substances such as K or Na hydroxides or carbonates, lime, HCl , H_3PO_4 , HNO_3 , chlorides or compds. evolving Cl, phosphates, nitrates, sulfates, bisulfates, sulfides, peroxides, perchlorates or other persalts or oxidizing agents or org. acids or salts and heated. Cf. C. A. 22, 2817.

Activated carbon. METALLBANK UND METALLURGISCHE GES. A.-G. and E. SCHELLER. Brit. 292,039, Jan. 4, 1928. Carbonaceous materials such as wood, sawdust, peat, starch, sugar or lignite are carbonized and activated by treatment at high temp with Na_2O , and carbonized material may be similarly activated or reactivated. The process is preferably conducted *in vacuo* or in an inert gas such as N.

Adsorptive carbon. CARRIDE AND CARBON CHEMICALS CORP. Fr. 642,360, Sept. 30, 1927. A non-coking coal mixed with a carbonizing agent such as ZnCl_2 is calcined at a high temp. to produce an adsorptive C. The activation may be carried further by a limited oxidation with steam for example.

Increasing adsorptive power of charcoal. HARVEY B. LEMON. U. S. 1,699,243, Jan. 15. Suction is applied to vegetable charcoal while heating to $450-800^\circ$, a permanent gas such as air is subsequently adsorbed in the charcoal at a temp. substantially below 0° (suitably "liquid air temp.") and the gas is then removed by suction at a temp. of $450-900^\circ$.

Adsorbent. ARTHUR ROSENHEIM. Fr. 641,549, July 27, 1927. Natural or artificial zeolites or substances resembling them after extn. of the bases (alk. or alkali metal) which they contain are used as adsorbents for dissolved substances, gases or vapors. Cf. C. A. 23, 679.

Adsorbents. LURGI GESELLSCHAFT FÜR WARMETECHNIK M.B.H. Fr. 642,135, Oct. 10, 1927. The ashes recovered from the gases escaping from furnaces of all kinds are used as adsorbent agents, e. g., for clarifying liquids. The ashes are sorted after recovery and activated by washing with water and acids. Cf. C. A. 22, 3270.

Catalyzers. I. G. FARBENIND. A.-G. Swiss 127,516, Mar. 26, 1927. A Ni

catalyzer especially suitable for reducing or hydrogenating org. compds. is deposited by an electropositive metal in an aq. soln. of a Ni salt in the presence of a base. Thus, NiCl_2 is dissolved in water and mixed with NH_4Cl and concd. NH_4OH . Diatomaceous earth and powd. Al are stirred in, causing Ni to sep. Other bases which may be used are urea, PhNH_2 , toluidine, pyridine, MeNH_2 , piperidine, and hexahydroaniline.

Catalysts for the production of methanol, etc. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 642,318, Sept. 5, 1927. Catalysts for the production of MeOH and other compds. from CO and H are prepd. by heating a mixt. of ZnCO_3 or basic ZnCO_3 and a Cr compd. which may be ZnCrO_4 or basic ZnCrO_4 , in which case the heating takes place in the presence of H or the reacting gases. Examples are given in which (1) ZnSO_4 is boiled with Na_2CO_3 and the washed ppt. is digested with chromic acid; (2) aq. solns. of ZnSO_4 , Na_2CO_3 and $\text{Na}_2\text{Cr}_2\text{O}_7$ are heated together and the ppt. is washed.

Platinum catalyst. TIBOR VON ARTNER. Swiss 127,224, Feb. 14, 1927. To avoid deposition of Pt in the interior of a support, where it is less useful, the support is impregnated with a volatile liquid before treatment with the Pt soln. and is then dried. The volatile liquid may contain CH_3O or other reducing agent for the Pt soln. Cf. Brit. 265,938 (C. A. 22, 482).

Manufacture of nickel catalyst. I. G. FARBENIND. A.-G. Swiss 127,157, July 20, 1926. Addn. to 123,728. A soln. of a Ni salt contg. a support is treated with Na_2CO_3 soln. in the warm to ppt. NiCO_3 in cryst. form on the support. The product is reduced in H at 450° . Cf. Brit. 255,884 (C. A. 21, 2965).

Catalyst for use in producing vanillin or for other purposes. FRIEDRICH W. WEBER. U. S. 1,698,009, Jan. 8. A porous catalyst comprises asbestos carrying in its capillary spaces a ppt. of SiO_2 and Th oxide.

Catalytic reactions. I. G. FARBENIND. A.-G. Fr. 641,652, Sept. 29, 1927. Highly active catalysts are prepd. by pptg. finely divided metals from solns. of their salts by the reducing action of O compds. of Si, in the presence of carriers if necessary. In an example PhNO_2 is reduced to PhNH_2 by H under pressure in the presence of Ni obtained by heating a soln. of $(\text{AcO})_2\text{Ni}$ with oxydisiline, neutralizing the AcOH and washing. Other examples of reduction are given. For oxidation Os or Ir obtained in the same way may be used, and for reduction Au, Sn, Ag, Co, Pb, Tl or Bi may also be used.

Condensation products of urea. I. G. FARBENIND. A.-G. Fr. 641,770, Oct. 3, 1927. Oily or resinous condensation products of urea with alcs. or ketones or their derivs. are obtained by heating urea with an excess of alc. or ketone, and if desired with the addn. of a catalyst and under pressure. The products may be treated with CH_2O . Cf. C. A. 22, 3056.

Urea condensation products. I. G. FARBENIND. A.-G. Fr. 641,420, Sept. 11, 1926. Condensation products are produced by dissolving urea or its derivs. and CH_2O , preferably separately, in org. solvents, in the presence of little or no water, and heating them together with or without condensing agents. Solvents such as ethylene chlorohydrin, glycol monoacetate or monoalkyl ethers of glycol are suitable. The soln. of urea is preferably poured into the soln. of CH_2O .

Condensation products of aldehydes with urea and thiourea. KUNSTHAZFABRIK. F. POLLAK GES. Brit. 291,366, May 31, 1927. Clear homogeneous products are obtained by pressing condensation products such as those of urea or thiourea and CH_2O , in a powdered form which is capable of swelling and which contains but little CH_2O . The products must be of a low degree of polymerization and a minimum quantity of acid salt should be used for gelatinization and the water present must be removed from the gel at a low temp. (suitably *in vacuo*). NH_3 may be used for removal of excess CH_2O . Dry NH_4 salts also may be added as may also fillers, etc. Cf. C. A. 22, 1659.

Condensation products from aldehydes and phenols. G. S. PETROV. Russ. 4,538, Mar. 31, 1928. Acid and alk. catalysts are added to Cl derivs. of ethane and ethylene boiling above 100° and this mixt. is then added to the semi-condensed products from phenols and aldehydes followed by the usual final condensation in forms.

Plastic compounds. A. E. PORAI-KOSHITZ and G. S. PETROV. Russ. 3951, July 31, 1928. Fillers such as hydrocellulose (in the form of the waste product obtained in the manuf. of furfural), husks, shells from seeds, etc., are treated with acids and added to the usual components of plastic compds.

Agglomeration of plastic substances. DE CARSLADE AND REGIMBEAU. Fr. 641,896, Mar. 12, 1927. The agglomeration of plastic substances having a basis of casein is carried out in an app. under vacuum to avoid the formation of air bubbles.

Plastic compositions containing sulfur. F. N. BURT CO., LTD. Brit. 291,500,

Feb. 28, 1927. Cellulose or other porous material is impregnated with a larger quantity of S to which has been added a substance (designated as an "introfier") which decreases the viscosity, such as $C_{10}H_8$ or $C_{14}H_{10}$ or their derivs., diphenyl, di- or triphenylmethane, benzyl ether, dibenzyl ketone, fluorene, carbazole, naphthols, naphthylamines, tetrahydronaphthalenes, mono-, di-, tri-, tetra- or penta-chloronaphthalenes, quinoline or triphenylphosphate. A temp. of 130–135° is suitable for effecting the impregnation.

Metal mold for albuminous plastic masses. MÜLLER & MANN. Ger. 469,280, April 29, 1925. The mold has a coating of Cr or Cr alloy.

Method and apparatus for pressing plastic casein. GEBRÜDER ECKERT. Ger. 470,104, Feb. 3, 1925.

Metallic ornamentation of articles formed of casein. A. I. G. WARREN and PRECIOUS METAL INDUSTRIES, LTD. Brit. 291,877, Mar. 10, 1927. Metallic decorations are pressed into the casein while enclosed in a vessel contg. steam under pressure.

Molded products from casein and cellulose derivatives. G. JAKOVA-MERTURI and J. A. POGGIOLI. Brit. 291,765, June 8, 1927. See Fr. 635,637 (C. A. 22, 4739.)

Use of bakelite or a similar product for making closures or receptacles for foods, etc. BAKELITE CORP. Brit. 291,403, June 1, 1927.

Molding board and pattern plate composition. KARL WERNER (to Wilhelm Christoffers). Can. 285,973, Dec. 25, 1928. A compn. for producing molding and pattern plates consists of the double silicates appearing in the production of Al by means of bauxite, or the residues contg. silicic acid left over in the production of Al sulfate and alum, or both residues simultaneously, combined with magnesia cement.

Sulfur composition for use in making molded articles. CARLETON ELLIS (to Ellis-Foster Co.). U. S. 1,699,694, Jan. 22. A dry dispersion is formed of S and a material such as starch, gum tragacanth and highly colloidal clay together with a filler such as wood flour or asbestos. The material may be molded by hot pressing and when thus molded has a strength greater than that of a similar material formed with undispersed S. The dried dispersion may be mixed with water to form an aq. dispersion.

Wetting agents. H. T. BÖHME A.-G. Brit. 291,070, May 27, 1927. Wetting and penetrating properties of liquid used in the textile and leather industries are improved by adding a mixt. of a heterocyclic compd. and an aromatic sulfonic acid alkylated in the nucleus, preferably a sulfonic acid of an alkylated polynuclear hydrocarbon, e. g., a suitable compn. may be prepd. by heating dipropyl-naphthalenesulfonic acid with pyridine bases. Other examples are given.

Wetting agents. H. T. BÖHME A.-G. Brit. 291,096, May 27, 1927; Fr. 641,629, Sept. 28, 1927. Wetting and penetrating properties of liquids used in the textile and leather industries are improved by the addition of a mixt. of a heterocyclic compd. and an aromatic sulfonic acid alkylated in the nucleus, both of which ingredients may be hydrogenated. By heating the mixt. before use, a salt-like compd. is produced which is especially efficient. Dipropyl-naphthalenesulfonic acid may be heated with pyridine bases, and other similar examples also are given.

Detergent. AMEDEO MENGHINI. Fr. 642,039, Oct. 6, 1927. A detergent for glass, metal, etc., consists of tripoli or like earth mixed in aq. solns. of weak acids such as oxalic or salicylic.

Cleansing and emulsifying agents. I. G. FARBENIND. A.-G. Swiss 127,222, Nov. 15, 1926. Cleansing and emulsifying agents comprise a known cleansing, etc., agent of the sulfonic acid type and a water-sol. salt of another acid. Mixts. of the Na salt of butyl-naphthalenesulfonic acid with Na_2SO_4 , and of the Na salts of butyl-naphthalenesulfonic acid and isopropyl-naphthalenesulfonic acid are described by way of example. Water-insol. org. compds. may be included in the compns.

Cleansing and emulsifying agent. CHEMISCHE FABRIK. POTT & Co. Swiss 127,252, Dec. 27, 1926. A water-sol. condensation product of α -naphthalenesulfonic acid, having good cleansing and emulsifying properties, is prepd. by the interaction of naphthalene, a sulfonating agent and butylene, or from α -naphthalenesulfonic acid and butylene, in either case in the presence of a condensing agent. Alternatively, naphthalene and butylene may be brought to reaction in the presence of a condensing agent and the product then sulfonated. Cf. C. A. 22, 880.

Cleaning fatty or oily vessels. GUSTAV BOHNSACK. Ger. 469,504, Jan. 8, 1928. The cleaning agent is an aq. suspension of kaolin which has been finely ground, washed, dried and re-ground.

Paint removers. CARBIDE AND CARBON CHEMICALS CORPORATION. Fr. 641,616, Sept. 28, 1927. Polyglycols or their mono- or di-aryl or alkyl ethers are used as paint removers. Fr. 641,617 describes the use for the same purpose of esters of glycol or polyglycol ethers such as the acetate of the Et ether of diethylene glycol.

Removing paint and varnish. F. C. DEAN and O. P. SWIFT. Brit. 291,812, Dec. 8, 1928. See Can. 283,159 (C. A. 22, 4215).

Cement. SANDFORD S. COLE (to The Koppers Co.). Can. 285,932, Dec. 25, 1928. A refractory cement which contains approx. 87.8% silica, 0.2% of Prussian blue and 2% of borax is specified.

Metal cement. WILLIAM R. CHAPIN. U. S. 1,699,346, Jan. 15. A cement suitable for joining pieces of steel comprises silico-Mn about 60, powdered Ni 25 or less, powdered borax glass 10 or less and ferro-Si about 10%, all thoroughly mixed in powdered form.

Desulfurization of pyrite ash. ITALO CAVALLI. Fr. 641,401, Sept. 26, 1927. S contained in pyrite ash is oxidized with an alkali hypochlorite, the solns. being recovered and used again for the production of hypochlorite.

Bodies of pressed powdered magnetic material. WALTHER EHLERS (to General Electric Co.). U. S. 1,698,300, Jan. 8. In forming articles such as magnetic cores loading coils a mass of powdered material is subjected to a regulated pressure within range over which the d. of the material remains substantially const. with variations in the pressure employed.

Laminated sheets of fibrous material. JAMES MCINTOSH (to Diamond State Fibre Co.). U. S. 1,697,077, Jan. 1. Fibrous sheets such as paper, asbestos or textile fabric are passed through a soln. of cellulose acetate or nitrate or other suitable cellulose ester, the solvent is evapd. and dried sheets are superposed on each other to form a product of the desired thickness and are heated under pressure. The product is suitable for gears, radio panels, etc. Synthetic resins, etc., may be added.

Treating asbestos or similar mineral fibers. SOC. GÉNÉRALE D'EXPLOITATIONS INDUSTRIELLES. Brit. 291,002, May 23, 1927. Asbestos or like material is treated with acid reagents such as dil. H_2SO_4 to facilitate opening up and to improve the adhesion of binding agents. Fibers which are not attacked by dil. acid are treated before their opening up with an alk. silicate and subsequently with acid.

Separating asbestos fiber from crushed rock by use of water and mechanical treatment. H. SIMON, LTD., and F. R. JOLLEY. Brit. 291,864, March 8, 1927. An app. is described.

Matrix board for stereotyper's use. HOWARD J. BLAKE. U. S. 1,699,579, Jan. 22. A fibrous flong or mat for a matrix blank has a coating of cellulose xanthate which serves to render it more durable.

Reflector for producing colored light effects. BOHUMIL JIROTKA (to Otto Sprenger Patentverwertung Jirotká m. b. H.). U. S. 1,697,655, Jan. 1. Reflectors suitable for use in illuminating fountains, etc., comprise small metallic areas made iridescent by treatment in a metallic bath contg. Cr, Co, Cu, Ag and Mn.

Colored substances from volatile metal compounds. I. G. FARBENIND. A.-G. (Walter Schubardt and Marta Grote, inventors). Ger. 466,463, June 16, 1928. Metal powder, prepd. by decomposing volatile compds. such as metal carbonyls, is subjected to oxidation at a temp. chosen to produce the desired color. The powder may be previously mixed with an oxidizing agent.

Fabric for pulley coverings. EDWARD F. GINGRAS. U. S. 1,697,236, Jan. 1. A belting fabric is satd. with a gum soln. such as copal gum in acetone which when hardened will prevent the stretching or contracting of the material, excess moisture is allowed to evap. and the surface is coated with a rubber soln. and stretched to approx. its elastic limit and held under tension until completely dry.

Wax-like coating compositions. BRITISH DYE STUFFS CORP., LTD., J. B. PAYMAN AND W. GIBSON. Brit. 292,057, March 4, 1927. Coating compns. which adhere firmly to metals, paper, wood and other materials are prepd. by adding S to molten polychloronaphthalenes such as may be produced by the processes described in Brit. 291,849 and Brit. 292,056 (C. A. 23, 1139).

Cylindrical printing rolls with renewable metal coatings. ERNEST S. BALLARD (to Ballard Process Co.). U. S. reissue 17,179, Jan. 1. A permanent metallic cylindrical base which may be formed of Cu or brass carries a smooth or polished outer layer such as Cu which does not permanently unite with the base and which is suitable for carrying an electrodeposited surface layer and to receive an engraved image. An intermediate layer of alloy of low m. p. is used.

Stencil sheet. SHINJIRO HORII. U. S. 1,698,705, Jan. 8. A base of fibrous material such as yoshino paper carries an impregnating compn. comprising a natural or synthetic resin, cellulose nitrate or cellulose or mannan acetate or other suitable esters of polysaccharides and a tempering agent such as stearin and castor oil. Cf. C. A. 23, 680.

Chemically heated appliance (similar to a hot water bag) for personal use. W. REICHMANN (to Radio Pack Co., Ges.). Brit. 290,212, May 9, 1927. A rubber-covered flexible heater may contain iron filings mixed with coal dust to which NaCl soln. or KCl, CaCl_2 or NH_4Cl is added when desired for generating heat.

Mirror. WILLIAM LAHODNY (to Standard Mirror Co.). U. S. 1,698,307, Jan. 8. A coating of light porous Ag is applied to the rear of a transparent material such as glass and over the Ag coating there is applied a protective material and over this a coating of opaque material.

Dry-cleaning composition for walls, etc. WALTER SPENGLER. Swiss 127,485, April 13, 1927. The compn., in the preferred proportions, comprises 20 g. CuSO_4 , 5 g. Na_2CO_3 , 5 g. alum and 15 drops NH_3 soln. in 500 cc. distd. water mixed with 500 g. wheat meal and a little disinfectant.

Purification of benzine and trichloroethylene. FIRME AUGUST JUNGNIKKEL. Fr. 641,836, Oct. 5, 1927. Crude benzine or trichloroethylene used for cleaning is purified in a continuous manner by aspiration from the washing machine through a primary filter, then through a second filter contg. laminated plates and then to the usual purifiers.

Polish. JOHN GOLAZ and MAURICE GAGNIÈRE. Fr. 642,410, Oct. 14, 1927. A liquid polish contains tripoli 0.5, colza oil 0.5, vitriol 0.025, turpentine oil 0.5, AcOH 1.0, distd. H_2O 5.0 g.

Polishing compositions. BRITISH DYESTUFFS CORP., LTD., J. B. PAYMAN and W. GIBSON. Brit. 292,058, March 4, 1927. Waterproof polishes for wood, linoleum, varnished surfaces, etc., are prepd. by adding α -chloronaphthalene to polychloronaphthalenes such as those produced by the process described in Brit. 291,849 and in Brit. 292,056 (C. A. 23, 1139).

Composition for protecting the skin or other surfaces from dirt and dust. ERNST TEUFEL. U. S. 1,697,936, Jan. 8. A pasty compn. is formed of Na soap 18, K soap 9, waterglass 22, talcum 12 and 20% alc. 90 parts.

Preserving ether in tin cans. EDWARD MALLINCKRODT, JR., and HENRY V. FARR (to Mallinckrodt Chemical Works). U. S. 1,697,320, Jan. 1. A tin can for holding ether has a complete inner surface of material such as bakelite varnish or a coating formed by reaction of KMnO_4 on the Sn which is non-catalytic to ether and air placed in the can and the can also has a cap of non-catalytic material.

Material for brake linings. RICHARD J. EVANS (to Asbestos Mfg. Co.). U. S. 1,700,037, Jan. 22. Cords of wire and twisted asbestos are treated with a soln. of Na silicate, formed into a basket weave fabric of equal spacing and strength in both directions, heated and dried, treated on one side only with a coating of plastic rubber and friction material and subjected to heat and pressure and a plurality of plies of this material are then united by heat and pressure.

Fluid for use in pressure systems such as those of hydraulic brakes. ANDREW T. K. TSENG (to Hydraulic Brake Co.). U. S. 1,698,973, Jan. 15. A mixt. is formed of castor oil 7 gals., dibutyl phthalate 3 gals., an alkali metal hydroxide such as KOH in proportion to free fatty acid present and an alkali metal As salt such as K arsenate which serves to prevent corrosion.

Acid-resisting packing suitable for use with sulfuric acid, etc. WALTER RAUTENSTRAUCH (to Metalastic Inc.). U. S. 1,698,655, Jan. 8. A packing contg. a large proportion of Pb particles contains also asbestos and a coating of acid-resistant waxy material such as paraffin and graphite some of which constitutes a coating on the particle of other materials.

Packing for use with steam turbines, etc. WALTER RAUTENSTRAUCH (to Metalastic Inc.). U. S. 1,698,654, Jan. 8. Cu or other suitable metallic particles of high m. p. are mixed with graphite, tallow and a fibrous material such as asbestos which is resistant to heat and another fibrous material such as flax which will burn out when the packing is subjected to heat and benzaldehyde also may be added.

Packing for use in stuffing-boxes, etc. HUGH T. STEWART (to Metalastic Inc.). U. S. 1,698,660, Jan. 8. Fibrous material such as carded asbestos is mixed with oil, particles of antifricition metal such as babbitt metal are added and the mixing is continued, a solid lubricant such as graphite is then added and the materials are still further mixed.

"Hot joint paste." WILLIAM HOSKINS (to Standard Oil Development Co.). U. S. 1,699,294, Jan. 15. A paste suitable for sealing pipe joints exposed to high temps. comprises graphite and solids from sulfite liquor.

Cooling liquid. I. G. FARBERIND. A.-G. Swiss 127,369, Mar. 2, 1927. A cooling liquid of low f. p. for use with motors, etc., contains at least one monoalkyl ether of a

bivalent alc., with or without a polyglycol or a monoalkyl ether thereof, or glycol or Pr alc.

Irradiating liquids. HERMANN SCHOLL. Can. 285,853, Dec. 25, 1928. Liquids to be irradiated with ultra-violet rays are first freed from air dissolved or otherwise admixed therewith to prevent the formation of O_3 by passing a gas either inert or chemically active, as desired, through the liquid, after which the liquid is distributed in shallow layers and subjected to ultra-violet ray treatment. Cf. C. A. 22, 4015.

Reheating saline solutions. GERHARD JANDER and HANS BANTHEIN. Fr. 641,530, Sept. 27, 1927. To protect the Cu pipes, saline solns. in the potash industry are passed through filters contg. substances to reduce the Fe, before reheating.

Waterproofing. KARL WILHARM. Ger. 469,217, Oct. 1, 1927. Natural horn or articles made by pressing powd. horn are rendered waterproof by treating with a soln. of $ZnCl_2$ to which $(AcO)_3Al$ or $HgCl_2$ is added.

Acid-proof material. I. G. FARBENIND. A.-G. Fr. 640,938, Aug. 29, 1927. See Brit. 276,697 (C. A. 22, 2476).

Moth-proof goods. I. G. FARBENIND. A.-G. (Erich Hartmann, Wilhelm Lommel and Hermann Stötter, inventors). Ger. 469,256. June 24, 1926. A dry powder contg. talcum and 5% chlorocresotic acid is revolved in a drum with fur or other goods. After the removal of the powder, the goods are moth-proof. The anti-moth prepn. described in Ger. 347,722 may be used with or without the addn. of AcOH. Cf. C. A. 23, 290.

Stiffening for footwear. MAURICE MOREL. Swiss 127,231, June 30, 1927. Leather, felt, cardboard or fabric is impregnated, before cutting out, with a soln. contg. at least one cellulose ester, allowed to dry, and then, when required for use, treated with a soln. which softens it temporarily. The first soln. may comprise, in parts, nitro-cellulose 20, camphor 10, acetone 100, benzine 50, alcohol 50, ether 50, copal 20, ocher 10, and preferably also kaolin 5 and plaster 25. The second soln. may comprise, in parts, cellulose acetate 30, acetone 250, benzyl alcohol 10, tricresylphosphate 5, abietic acid 20, ZnO or other pigment 25. Cf. C. A. 22, 2272.

Shoe-bottom filler. ANDREW THOMA (to North American Chemical Co.). U. S. 1,698,806, Jan. 15. Starch and a "sleeking constituent" such as Na_2CO_3 are mixed while both are in powdered form and this mixt. is then intermixed with a separately prepd. mixt. contg. granular and sticky material such as cork and wax tailings.

Extraction of vegetable and animal material. SCIENTIFIC CHEMICO PHARMACEUTICAL INST. OF THE N. T. U. Russ. 3,575, June 30, 1928. Exts. of the above materials obtained by one of the known methods are treated with a strong soln. of tannin to ppt. the solid material, followed by a treatment with a soln. of barite to ppt. the excess of tannin. The excess of barite is eliminated by an immediate pptn. with H_2SO_4 .

Treating animal intestines. MORITZ NIESZNER. Austrian 110,001, Feb. 15, 1928. The intestines are swollen with $NaHCO_3$ soln., stretched diametrically by mech. means, and finally hardened with alum soln.

Vermin-destroying composition. ANDREAS BURTSCHER. Swiss 127,471, Sept. 1, 1927. The compn. contains 5% CaO , 5% yellow ocher, 50% $B(OH)_3$ or a borate, and 40% Na_2CO_3 . It is effective against cockroaches, rats and mice.

Fire extinguisher. ÉMILE BÉCHARD. Fr. 641,438, Aug. 12, 1927. Fire extinguishers, such as CCl_4 , tetrachlorethane, trichloroethylene, are mixed with fatty substances at the moment of use. Agglomerants such as $C_{10}H_8$, naphthol, glycerol, etc., may be added. Cf. C. A. 22, 3502.

Automatic fire extinguisher. A. G. KRIVOSHEYEV. Russ. 4930, Mar. 31, 1928. The app. is set in action through melting of an alloy of low m. p.

Foam fire extinguisher. S. Y. BORUNSKII. Russ. 3696, Sept. 30, 1927.

Foam fire extinguishers. G. S. DOLGORUKOV. Russ. 3708-9, Sept. 15, 1924.

Foam fire extinguisher. S. Y. BORUNSKII. Russ. 4427, Jan. 31, 1928.

Portable foam fire extinguisher. S. YU. BORUNSKII. Russ. 4841, Mar. 31, 1928.

Foam fire extinguisher. L. I. YANISHEVSKII. Russ. 3867, Oct. 31, 1927.

Acid tube for portable fire extinguisher. FRIEDRICH RIEDL. Austrian 109,840, Jan. 15, 1928. The tube has strong side walls and weak end walls and is so constructed that both the end walls are fractured when the extinguisher is used.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON AND C. H. KERR

Conveying the glass from the melting furnace to the place of fabrication. L. BOCK. *Sprechsaal* 61, 621-2(1928).—The molding and shaping of glass took place at the melting furnace until quite recently. Transporting of the molten glass required either the use of the blowers pipe or a ladle. On account of the necessity of working the glass within narrow temp. limits the transportation of the liquid glass caused great inconveniences. To overcome these troubles a sep. working hearth for the molten glass was built and the glass was run from the melting tank to the hearth by means of a channel all of which were kept at the required working temps. of the glass. A description of the construction is included.

R. A. HEINDL

Glass tank refractories and their chemical relationship with the molten glass. KAI-CHING LU. Ohio State Univ. Eng. Expt. Sta., *Bull.* No. 44, 40 pp.(1928).—The corrosion of glass-tank blocks depends upon chem. action and upon the mech. texture of the block. Factors influencing corrosion were studied by means of chem. and microscopic analysis. An aluminous clay (Mandle Porter No. 4) and a siliceous clay made by mixing 60% ground flint with the former were used. The life of a refractory depends upon the rate of formation and soln. of a porcelainous surface at the glass interface. Mullite was sepd. from this layer by digestion with 15% HF. The aluminous clay burned to cone 28 contained about 46% mullite; the siliceous clay burned to cone 23 contained about 14%. The presence of impurities seemed to aid the crystn. of mullite. The rate of soln. is less in the aluminous refractory than in a highly siliceous one. No volatilization of alkalis took place on heating the aluminous refractory to cone 16 for 60 hrs. The presence of mullite in the white layer of a used tank block was verified microscopically. About 20 to 30% mullite was found in the glassy matrix. The brown glassy layer which covers the white layer was found to contain labradorite crystals and a little mullite. Analysis of this glass showed its chem. compn. to be near that of feldspar. In a highly siliceous refractory this brown glass is replaced by a white layer which contains cristobalite. The viscosity of the aluminous glass matrix was estd. to be about half that of the siliceous matrix at their respective m. ps.

A. L. BADGER

Chemical composition and properties of some special kinds of glass. I. A. PRSHEL AND D. N. POPOV. *Trans. Sci. Chem.-Pharm. Inst. (Moscow)* No. 9, 9-35(1924).—The results are given of a series of phys. and chem. analyses of glassware used in chem. pharmaceutical work.

J. S. JOFFE

Determination of alkalinity of glass for medical ampouls. D. N. POPOV AND B. A. KLYACHKINA. *Trans. Sci. Chem.-Pharm. Inst. (Moscow)* No. 9, 36-44(1924).—P. and K. present analyses of ampouls for the excess of alkali present in them.

J. S. JOFFE

Opacification of lime-lead glass and alumina-lead glass. SUKEAKI SAKAI. Mazda Research Inst., Tokyo. *Bull. Mazda Research Inst.* 3, 51-8(1928).—On a lime-lead-soda glass (LF-5), and alumina-lead-soda glasses (AF-3 and AF-6) the opacification test was made by means of the following 4 methods of heating. (A) Heat gradually to a definite temp. and keep at this temp. for some time. (B) Heat rapidly up to this temp. and keep at this temp. for some time. (C) Cool from the melt to a definite temp. (D) Cool once from the melt to a lower temp. and then gradually heat to a definite temp. LF-5, contg. less than 1.5% Al_2O_3 , is more likely to opacify than AF-3 and AF-6 contg. 3.4 and 2.4% Al_2O_3 . LF-5 begins to become opaque at about 600° and becomes most so at 750-800°. AF-3 and AF-6 are very difficult to opacify; the crystal first formed vanishes again above 1000°. The difference between the results of the treatment according to (C) and (D) is not clear. In the treatment (D), those first cooled to room temp. and then kept at a definite higher temp. for a few hrs. are more liable to become opaque. The boundary between the clear portion and the milky cryst. portion is clearly recognizable, the formation of a fissure taking place at the boundary by reason of the difference of expansion coeff. The opacification begins at the portions which are in contact with the outside atm. or with some such substance as a refractory material, or with a small particle of stone which is present as an inclusion.

K. SOMEYA

A discussion leading to the clear understanding of "increasing" or "decreasing" decolorization. ANON. *Sprechsaal* 61, 622-3(1928).—A discussion on decoloration of

glasses on the basis of the following classification: I. Decreasing: (A) chem. decolorization (oxidation of the ferrous oxides to ferric oxide as with the aid of saltpeter); (B) phys. decolorization (withholding iron from the melt; less impurities in raw materials and chemicals). II. Increasing: Suppression of the tinge (of color) by means of its complementary color.

Dangerous incidents in the preparation of mirror coatings. WALTER MEYER. *Sprechsaal* 61, 599-601(1928).—A discussion on the reactions occurring in the prepn. for coatings for silvering mirrors, the dangers incident to the prepn. of certain explosive mixts. and the application of these prepn. R. A. HEINDL

The problem of obtaining raw clays which are not washed away by water. P. P. BUDNIKOV. *Trans. State Expt. Inst. Silicates* (Moscow) No. 21, 97-106(1927).—One type of clay was treated with NaOH, KOH, $\text{Ca}(\text{OH})_2$, FeSO_4 , $\text{Al}_2(\text{SO}_4)_3$, CaSO_4 , $(\text{NH}_4)_2\text{SO}_4$, $\text{Cr}(\text{CH}_3\text{COO})_3$, Na_2S , CuSO_4 , NaHSO_4 , CrO_3 , H_2SO_4 , H_3PO_4 , HCl , HNO_3 , made up into a dough, shaped into pyramids, air dried and then immersed in H_2O . The HNO_3 - and HCl -treated clays did not dry out and were not tested. The time period for the variously treated clays to disintegrate when immersed in H_2O is recorded in tables. Of the alkalis only $\text{Ca}(\text{OH})_2$ (5% and higher) increased the stability of the clay to such an extent that the pyramid retained its shape for a long time (the exact period is not given). Of the different salts and acids, H_3PO_4 was most effective. From 3 to 5% of H_3PO_4 gave the best results. Samples of clay thus treated were immersed in H_2O for more than a year and showed no signs of disintegration. $\text{Ca}_3(\text{PO}_4)_2$ with enough H_2SO_4 to give from 3 to 6% H_3PO_4 gave the same results as with H_3PO_4 alone. Tests showed that the H_3PO_4 or H_2SO_4 additions decrease the burning shrinkage. Clays with different SiO_2 contents (from 5.5 to 42.5%) when treated with H_2SO_4 or $\text{Ca}_3(\text{PO}_4)_2 + \text{H}_2\text{SO}_4$ manifested stability up to 21.7% SiO_2 content. Superphosphate + H_2SO_4 was not effective, but additions of 10% asbestos to this treatment made the clays stable. Attempts to clear up the factors responsible for the behavior of clays upon the addition of H_3PO_4 , H_2SO_4 , $\text{Ca}_3(\text{PO}_4)_2 + \text{H}_2\text{SO}_4$, were futile. $\text{Fe}(\text{OH})_3$, $\text{Al}(\text{OH})_3$, addus. or humus from raw peat gave no clue as to what is happening. J. S. JOFFE

Clay gels. D. G. R. BONNELL. Univ. of Göttingen. *Z. anorg. allgem. Chem.* 176, 116-22(1928).—Different samples of clay have been prepd. according to Willstätter (C. A. 18, 2990). Their ability to adsorb malachite green, methyl violet, methylene blue, Congo red, nigrosin, azo blue, Bordeaux extra and eosin has been investigated. The acid dyes are much more adsorbed than the basic ones. In each case the amt. adsorbed is practically independent of the method of prepn. of the clay. It is concluded that the size of the clay particles has a negligible effect. In prepg. the clay samples, the more HCl used for peptization, the smaller the particle size. A. L. H.

Waterproofing clays. B. S. SHVETZOV AND K. G. ELSHANKIN. *Trans. State Expt. Inst. Silicates* (Moscow) No. 21, 73-89(1927).—Different clays when made up to a dough, or air dried, differ in their rate of disintegration when immersed in H_2O . The problem was to increase the time interval necessary for the H_2O to penetrate the clay, thus giving it greater stability. Addns. of Na_2SO_4 , CuSO_4 or CaCl_2 showed no effect. H_2SO_4 and Na_2SiO_3 alone and mixts. of these in different proportions increased the time from 7 or 9 mins. to 2 hrs. and 45 mins. for the 5 cc. addn. of a 10% H_2SO_4 soln. to 18 g. of clay. Several other trials with different per cents of H_2SO_4 showed that 2-3% is the best amt. The authors do not explain the possible reactions which might cause these clays to resist the entrance of H_2O upon treating with H_2SO_4 . They suggest the possible formation of compds. of the oxides of Al and Fe with SO_4 . When fibrous material, such as asbestos or peat, was added in conjunction with H_2SO_4 , the clay did not form any cracks, but the time interval was not increased. The H_2SO_4 has no effect on shrinkage. J. S. JOFFE

The action of sulfuric acid on clay at ordinary temperatures. P. N. GRIGOR'EV AND P. I. GALKIN. *Trans. State Expt. Inst. Silicates* (Moscow) No. 21, 91-5(1927).—The authors conducted a series of expts. to det. the chemistry of the phenomenon reported by Shvetzov and Elshankin on the action of H_2SO_4 on the waterproofing of clays (cf. preceding abstr.) and formation of "keramolit" ("keramolit" is "waterproof" clay). The postulate was that gypsum is formed in the reaction between the Ca of the clay and the H_2SO_4 and this binds the clay. Eleven different kinds of clays and kaolins were treated with H_2SO_4 , kneaded into pyramids and immersed in H_2O . The time period the pyramids kept their shape under water served as an index for the effect of the H_2SO_4 on the waterproofing of the clays. The results of the expts. are summarized: (1) "Keramolit" cannot be prepd. from any clay. (2) There can be no set rule as to which of the clays is capable of forming "keramolit." (3) There is no proof that the formation of gypsum is responsible for imparting the "keramolit"

property to clays: Clays with a high Ca content gave no "keramolit" while other clays with a low Ca content did give "keramolit." (4) The explanation offered by the authors is the dehydration of the clays by the H_2SO_4 ; the presence of impurities in clays, especially Fe, seems effective in the formation of the "keramolit." J. S. J.

The volume increase of brick upon heating. P. I. GALKIN. *Trans. State Expt. Inst. Silicates* (Moscow) No. 21, 107-10(1927).—G. presents data on burning shrinkage and expansion of various clays. J. S. JOFFE

Suspensions of kaolin. A note. R. DUBRISAY AND ASTIER. *Compt. rend.* 187, 978-80(1928).—The effect of acid and alkali on the rate of flocculation of water suspensions of kaolin has been followed quant. HCl , Li_2O , Na_2O , K_2O and phosphate buffer solns. of varying p_H values were added to suspensions of washed kaolin, and the rate of descent of the division between the suspension and the clear, supernatant liquid was noted. When p_H is plotted against the rate of sedimentation, the values for all of the above solns., excepting the phosphate buffer, fall on the same curve. The minimum rate is at p_H 11.0-12.0. The protective action of acids and bases seems to depend on their ionization, but this is not the only factor, since the phosphate buffer causes more rapid sedimentation than the other solns. of the same p_H , and since alk. earths are known to coagulate kaolin at great diln. Nephelometric measurements on month-old suspensions of kaolin in Li_2O solns. show a max. of opacity at the same p_H as the min. sedimentation. Microscopic and ultra-microscopic examn. revealed particles left only in the suspensions in less than $N/30$ alkali. M. W. SEYMOUR

Methods of research newly applied to refractories. WILLIAM F. BOERCKE. *Mining & Met.* 10, 16-8(1929).—The theoretically perfect refractory would possess the following properties: (1) high softening and melting points under normal load, (2) high resistance against sudden and sharp changes of temp.; (3) chem. inertness when confronted with the influence of metal oxides, fluxes and products of combustion that cause corrosion; (4) min. possible change of shape and vol. under all furnace conditions; (5) high resistance to mech. stresses and shocks, in both hot and cold state; and (6) uniform compn. so that a buyer may be sure at all times to receive the same product. The characters of the phys. and chem. tests employed by the General Refractories Co. at their Baltimore, Md., plant are discussed. Increasing importance is being given to petrographic study. The petrographic microscope permits the study of component minerals present in the raw material, in partly processed minerals, and in finished brick. Transparent sections are examd., also the brick or mineral in finely powd. condition. Melts are made of 2 or 3 components in various concns. and then subjected to different temps. for varying lengths of time. Petrographic studies of various Al silicates point out the best means to form the max. amount of mullite which is the most stable high-temp. form of Al silicate. Other instances of the value of petrographic study are mentioned. W. H. BOYNTON

The requirements of modern refractory materials. A. T. GREEN. *Ind. Chemist* 4, 484-9(1928).—A table giving the sp. gr., porosity, refractoriness and coeff. of expansion of 10 kinds of refractory materials is followed by a discussion of industrial applications. A bibliography is appended. E. G. R. ARDAGH

A manufacturer's viewpoint regarding specifications (for refractories). GEORGE A. BALZ. *Am. Refractories Inst. Tech. Bull.* No. 26, 4 pp.(1928).—Specifications serve as a target at which manufacturers are either inclined or compelled to aim, and have contributed much to industrial progress. Danger lies in demanding materials to meet certain specifications as to manuf. and behavior that are not related to the uses of the given refractories in practice. In particular the water-spalling tests is a relic of the dark ages, and should be abandoned. Specifications should be prepd. jointly by manufacturers and users to ensure the greatest value to both parties. W. C. E.

Determination and separation of the alkalis [in glass] (THÜRMER) 7. Electric furnaces in the ceramic industries (HIND) 4. Refractories in the gas industry (SMITH, SPIERS) 21. Refractory materials. Their uses in vertical retorts (GREEN) 21. Invert sugar as a substitute for mannitol or glycerol in the titrimetric determination of boric acid (MYLUS) 7. Furnace for heat treating, enameling, etc. (U. S. pat. 1,697,373) 1. Mirror (U. S. pat. 1,698,307) 18. Drying tunnel for ceramic ware (U. S. pat. 1,697,556) 1. Forming deposits of latex, etc. (Brit. pat. 291,339) 30. Alloys for fusing in or on glass (Ger. pat. 469,630) 9. The mineral dumortierite (Mackay School of Mines Staff) 8.

Melting glass batch materials. R. L. FRANK. *Brit.* 291,853, March 29, 1911.

The materials are melted as they pass downwardly over an inclined hearth of a furnace, various structural details of which are described.

Mold for pressing glass objects. CHARLES E. SCHMUNK. Ger. 469,628, Jan. 24, 1925.

Apparatus for feeding mold charges of molten glass. ALBERT N. CRAMER (to Owens Bottle Co.). U. S. 1,699,563, Jan. 22.

Burner for glass furnaces. PAUL R. VITTE. U. S. 1,697,334, Jan. 1. Structural features of a burner utilizing oil.

Forming sheet glass. EDWARD DANNER. U. S. 1,697,227, Jan. 1. Mech. features.

Apparatus (with forming, conveying and lehr rolls) for making sheet glass. RICHARD D. HUMPHREYS (to Mississippi Glass Co.). U. S. 1,697,504, Jan. 1.

Traction rolls and associated apparatus for drawing glass. JOHN A. SWEET (to Pittsburgh Plate Glass Co.). U. S. 1,698,378, Jan. 8. Mech. features.

Regulating temperatures on opposite sides of the draw bar in a glass drawing tank. WALTER G. KOUPAL and JOSEPH S. GREGORIUS (to Pittsburgh Plate Glass Co.). U. S. 1,698,369, Jan. 8. Mech. features. An app. is described.

Drawing sheet glass. CLARENCE P. BYRNES. U. S. 1,697,104, Jan. 1. Mech. features. An app. is described.

Apparatus for drawing sheet glass. JOHN L. DRAKE (to Libbey-Owens Sheet Glass Co.). U. S. 1,698,492, Jan. 8. Structural features.

Apparatus for drawing glass. JEAN LADURÉ. Fr. 641,913. Mar. 15, 1927.

Pot-draining device for glass-blowing apparatus. FREDERICK A. OST. U. S. 1,698,000, Jan. 8. Structural features.

Conveyors for carrying glass sheets through leers. NAAMLÖÖZE VENOOTSCAP Nij. tot BEHEER EN EXPLOIT. VAN OCTROOIEN. Brit. 291,358, May 30, 1927. Structural features.

Tunnel and associated apparatus for annealing glassware. CLAUDE NAGLE (to Hartford-Empire Co.). U. S. 1,697,996, Jan. 8.

Apparatus for annealing sheet glass. VERGIL MULHOLLAND (to Hartford-Empire Co.). U. S. 1,698,479, Jan. 8.

Apparatus for annealing glassware. VERGIL MULHOLLAND (to Hartford-Empire Co.). U. S. 1,698,480, Jan. 8.

Means for feeding small glass objects into annealing leers. EMANUEL LINKE. Ger. 469,495, Dec. 10, 1926.

Means for feeding glass objects into annealing leers. PERCY Q. WILLIAMS. Ger. 469,629, Jan. 13, 1924.

Apparatus for uniting glass sheets under pressure. WILLIAM O. LYTLE (to Pittsburgh Plate Glass Co.). U. S. 1,698,371, Jan. 8.

Forming necks on hollow glass bodies. FELIX MEYER. U. S. 1,699,305, Jan. 15. Mech. features.

Apparatus for forming bottles or similar molded glass articles. RICHARD LA FRANCE (to Owens Bottle Co.). U. S. 1,699,566, Jan. 22.

Device for the separation of unbroken glass rods or tubes. GLASWERKE RUHR. A. G. Ger. 469,215, Mar. 11, 1926.

Colored glass. EDGAR J. BRASSEUR and WILLIAM R. GEDDES (to Libbey-Owens Sheet Glass Co.). U. S. 1,698,491, Jan. 8. A layer of colored glass is caused to flow upon the surface of a moving body of ordinary more or less colored glass and (by an app. which is described) a glass sheet is drawn upwardly which is plain on one side and colored on the other side.

Decolorizing or coloring borosilicate glasses. CORNING GLASS WORKS. Ger. 469,474, Mar. 5, 1922. See Brit. 194,888 (C. A. 17, 3590).

Coating glass surfaces. BYRON C. GOSS (to General Electric Co.). U. S. 1,698,302, Jan. 8. In order to form coatings which give "frosted" or similar effects, a liquid mixt. is applied which contains an insol. body material such as kaolin, MgO, Al₂O₃, and ZrO₂ together with Na silicate or other alk. silicate and an alk. hydrate such as NaOH in such proportions that there is present materially more of the alk. hydrate than is contained in commercial grades of the silicate; the coating thus formed is dried and is afterward treated with a fixing soln. such as ZnCl₂ and Al₂(SO₄)₃, which reacts to form insol. compds. Cf. C. A. 22, 2648.

Polishing glass surfaces. JOSEF PIVIN. U. S. 1,697,609, Jan. 1. See Brit. 263,858 (C. A. 22, 148).

Glass permitting passage of ultra-violet rays. SOC. ANON. DES MANUFACTURES DES GLACES ET PRODUITS CHIMIQUES DE SAINT-GOBAIN, CHAUNY, ET CIREY. Brit. 291,468, June 4, 1927. In order to counteract a tendency of glass transparent to ultra-

violet rays to lose this transparency a small proportion of Mn oxide is incorporated in the glass. Silica glass and transparent cast silica may be similarly treated.

Uniting glass objects with iron-chromium alloys by fusion. NAAMLÖÖZE VENNOTSCHAP. PHILIPS' GLOEILAMPENFABRIKEN. Ger. 468,555, Mar. 13, 1926. A small addn. of Al, suitably 0.5%, is made to the alloy before the fusion.

Bricks, tiles, etc. H. PARDOE, T. PARDOE and H. HILL. Brit. 291,960, June 14, 1927. Bricks, tiles and the like are made from pulverized slate or shale waste mixed with $1\frac{1}{2}$ -3% of Fe_2O_3 or of a siliceous Fe oxide ore. Water is added to effect binding when pressed and the compn. is then molded and is fired at a temp. of about 1000° . Mention is also made of the possible use of glass makers' waste, sand or slag together with Fe ore.

Impregnating composition for bricks, tiles, etc. JOHANN TANZER. Austrian 111,389, Mar. 15, 1928. The compn. comprises soft (tar) pitch, hard (coal) pitch, and a coal tar distillate of high b. p. (Carbol'neum) in the resp. proportions 60:38:2.

Artificial bricks and plastic hardening masses. A. A. BRYUSHKOV. Russ. 4824, Mar. 31, 1928. Small quantities of sulfonic acids from mineral oils are added to a mixt. of clay, tripoli, etc., and resin soap. No baking is required.

Decorated tiles. V. LEFEBURE. Brit. 291,884, March 11, 1927. Production of colored tiles contg. silicates and reacting oxides or salts and hardened by heat as described in Brit. 268,851 (C. A. 22, 1455) is modified by printing decorations with an ink contg. the same reacting ingredients, or some may be in the ink and some in the base. A fibrous material may be used as base material and impregnated with fillers and reacting substances.

Apparatus for coating flat tiles. LOUIS S. JONES, GARFIELD W. FISHER and CARL G. HENRIKSON (to National Tile Co.). U. S. 1,699,972, Jan. 22. The app. is suitable for applying glazing compds.

Silicon ware. I. G. FARBERIND. A.-G. Ger. 469,169. July 23, 1927. Addn. to Ger. 462,052. The acid-proof mass made from molten siliceous material described in the former patent is made into lining-plates. If heated to 1200° , the material is rendered alkali-proof.

Insulators for high-frequency currents. ALBERT E. MARSHALL (to Corning Glass Works). U. S. 1,700,066, Jan. 22. Insulators are formed of glass with a high silica content, a low alkali content, and contg. boric oxide.

Assembling portions of porcelain insulators while in plastic condition. KENT A. HAWLEY (to Locke Insulator Corp.). U. S. 1,699,063, Jan. 15. Mech. features.

Insulating material. STUDIEN-GES. FÜR WIRTSCHAFT U. INDUSTRIE M. B. H. Ger. 469,616, May 19, 1925. Addn. to 458,475. AlMg silicate prepd. by the method of Ger. 458,475, *i. e.*, by fusing MgCl_2 with quartz, feldspar and Al_2O_3 , with or without CaF_2 , and electrolyzing the melt, is used for insulating purposes. The silicate can be molded in fireproof molds.

Anti-damp covering for porcelain insulators. A. GROSSAUER. Swiss 127,627, Aug. 4, 1927. A coating of paraffin wax is used.

Cementing insulators. STUDIEN-GES. FÜR WIRTSCHAFT UND INDUSTRIE M. B. H. Ger. 469,015, July 7, 1925. Hydrocarbons and finely divided vulcanized rubber are added to a cement for earthenware insulators.

Apparatus for charging kilns with coal. KARL KOLLER. Austrian 110,995, May 15, 1928. App. is described whereby the coal is forced from the center to the upturned edge of a pan arranged over an annular charging opening.

Drainage system for brick kilns. THEO. F. MERTEN. Ger. 469,583, Feb. 16, 1927.

Stone door for annular kilns. OTTO BRADEMANN. Ger. 469,582, June 16, 1927.

Pottery kiln construction. H. WEBSTER. Brit. 291,482, Jan. 27, 1927.

Tunnel kiln suitable for burning clay products. GEORGE W. BOOTH. U. S. 1,698,700, Jan. 8.

Tunnel kiln for manufacture of ceramic ware, etc. AMERICAN ENCAUSTIC TILING Co., LTD. Brit. 291,504, Feb. 28, 1927. Structural features.

Ceramics. JOSEF BEIERL. Ger. 469,196, May 29. Raw potsherds are coated with a soln. of colophony in turpentine and a decorative pattern or picture is applied by transfer. The potsherd is then fired, after which the glaze is applied over the pattern in the usual way.

Ceramic materials. T. S. CURTIS. Brit. 291,524, March 3, 1927. A ceramic article is composed of fibrous mullite crystals and a binder; the crystals are produced by firing a natural alumina silica-bearing substance such as kyanite with addnl. alumina in splintery form.

Molding ceramic articles. T. S. CURTIS. Brit. 291,523, March 3, 1927. Materials are used in such form that they remain fluid while under constant vibration,

but solidify very rapidly on the vibration being stopped, and molding is effected while vibration is in progress. An electrolyte such as Na silicate may be added to promote fluidity. An arrangement of app. is described. Brit. 291,525 also relates to app. for use in processes of this character.

Molding ceramic or other material in vacuum under successively higher pressures. HENRY L. CROWLEY (to Isolantite Co. of America). U. S. 1,699,502, Jan. 15. Mech. features are specified of a method suitable for molding tubes or other articles.

Apparatus for baking ceramic articles. JOHANN MITTERER. Ger. 468,384, Feb. 12, 1928. A hood made of the same material as the articles protects them from contamination.

Muffle ceramic furnace. LÉON-LÉONARD DENIS. Fr. 641,397, Sept. 26, 1927. Constructional details of hearth and recuperation means.

Glass melting-pots and other refractory clay articles. J. HOCHHUT. Brit. 291,305, Dec. 12, 1927. A mixt. of "shortening material" such as burnt clay and disintegrated crucible shivers is mixed with clay and water to produce a loose, incoherent mass, and this material is introduced in successive small portions into an open mold and stamped, and then removed from the mold, dried and fired.

Making refractive materials by dry pressing. V. V. YURGANOV. Russ. 4916, Mar. 31, 1928. Clay, bauxite and magnesite which have not been roasted but have been dried and ground are mixed with materials which make the material porous after baking, pressed dry or slightly wet and baked. The shrinkage is thus minimized.

Coating for furnaces. VEREIN FÜR CHEM. UND METALLURGISCHE PRODUKTION. Fr. 641,181, Sept. 22, 1927. A refractory coating for furnaces is made of a mixt. of molten refractory substances, refractory clay, a binding agent and easily fusible sol. salt. In an example 100, parts of finely ground CeO_2 are mixed with 20 parts of bauxite and 0.5 of K_2SO_4 and agitated with water to obtain a mud.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

The setting of cement. I. HERMANN GESSNER. *Kolloid Z.* 46, 207-16(1928).—The modern theories are given and the work of the past few years is reviewed in the light of the colloid chem. aspect, with a discussion of the importance of particle size and degree of hydration. Some of the methods used for detg. particle size are given. Attempts to clear up the question of the chem. equil. between particle surface area and solution have failed. Work in regard to hydration in set cement is discussed with the conclusion that most of the water is held in a gel structure. The effect of aging on dehydration and crystn. is discussed. The outer shell of the particle apparently dehydrates while the inner part hydrates.

L. F. MAREK

Electrical investigation of the setting and hardening of rapid-hardening cements. YOSOMATSU SHIMIZU. Tohoku Imp. Univ. *Kinzoku-no-Kenkyu* (J. Study of Metals) 5, 217-82(1928); cf. *C. A.* 22, 1836.—The process taking place during the setting and hardening of the so-called "rapid-hardening cements," which are aluminous cements or super cements of the portland type, was studied by means of the elec.-resistance measurement. Two breaks, the first corresponding to the hydration of Ca aluminate and the second to that of Ca aluminosilicate or Ca silicate, were observed in the cond.-time curve of aluminous cements; but only one break, which corresponds to the hydration of the Ca aluminosilicate or Ca silicate was observed in that of super cements of the portland type. From these facts S. concludes that Ca aluminate does not exist in the clinker of portland cement, in agreement with Jänecke and Kühl. Also the fact that the rate of increase in the elec. cond. of alumina cements is much greater than that of the rapid hardening cement of the portland type is in agreement with the observation that the strength of the former is in its earlier stage of hardening much greater than that of the latter. S. also detd. the setting time of the above rapid-hardening cements from their time-cond. curve and studied the effect of temp. on the setting of those cements. The setting time detd. by this method of the alumina cement and of the rapid-hardening cements of the portland type does not differ much from each other, the result being also in agreement with that obtained by the method of Vicat's needle.

K. SOMEYA

Calcium chloride as setting accelerator for bore hole cement. V. N. KOREPANOV and E. K. MACHINSKII. *Neftyanoe Khozyaistvo* 15, 633-5(1928).—American CaCl_2 (76.13% CaCl_2 and 23.87% H_2O) and Russian (62.11% CaCl_2 and 37.89% H_2O)

were added to cement in various proportions. Breaking tests indicated that both types of CaCl_2 act alike when added to mortar with 25% of H_2O , the Russian CaCl_2 being superior at higher dilns. and the mortar mixt. having a higher strength after 4 and 7 days.

A. A. BOEHLINGK
Gypsum and anhydrite in the control of setting time. C. R. PLATZMANN. *Tonind.-Ztg.* 53, 59-61(1929).—A review of the literature. F. O. A.

Fused cements with a high alumina content. R. PERET. *Ann. ponts et chaussées* 1927, Nov./Dec.; *Building Sci. Abstracts* 1, 207; cf. C. A. 22, 149, 3024.—A comprehensive series of expts. has been carried out on binary and ternary systems of chemically pure SiO_2 , Al_2O_3 and lime. The fused materials have been cooled quickly, by quenching, or gradually, then ground to a uniform fineness and tested for strength, soundness and resistance to chem. attack. Contrary to experience with granulated slag, these products, if plunged in water while still fluid, give less favorable results than those cooled normally. Their setting time is shorter and their strength inferior. In general, the products fall into three classes: (1) those incapable of setting, (2) quick-setting cements of low strength, in some cases expanding or disintegrating in water after hardening, (3) slow-setting, high-strength products resistant to those salt solns. which are highly injurious to ordinary cements. A ternary diagram is given showing the zones occupied by the three classes mentioned, and details are presented in the form of a table. The diagram shows that the replacement of lime by silica, in a compd. of fixed alumina content, results in a rapid decrease in strength. The proportion of alumina should lie between 45 and 70 per cent; of lime, between 47 and 28 per cent; and of silica, between 12 and 0 per cent. These values hold only for chemically pure substances, the impurities present in commercial raw materials causing considerable modification. H. G.

Analysis of portland cement for factory purposes. WALTER J. PITT. *Chem. Eng. Mining Rev.* 20, 402-6(1928).—The methods described are excellent. The procedure is practically the same as that accepted as standard in this country. W. T. H.

Old vs. new methods of calculation of portland cement and clinker analyses. E. L. DRURY. *Rock Products* 32, No. 2, 57-8(1929). RAYMOND WILSON

Effect of calcium chloride and calcium oxychloride on portland cement. W. J. PITT. *Chem. Eng. Mining Rev.* 21, 65-70(1928).—Both of these chemicals accelerate the hardening of portland cement. RAYMOND WILSON

Flue dust—is it detrimental to portland cement? ALTON J. BLANK. *Rock Products* 32, No. 2, 48-50(1929). RAYMOND WILSON

Improving the qualities of concrete. C. H. BUTCHER. *Carp. & Build.* 102, 624(1928); *Building Sci. Abstracts* 1, 135.—The use of hydrated lime as an admixt. in portland cement concrete to render it watertight and increase plasticity is discussed. Tables are given showing the amt. to be added to mixes of various ratios. It is stated that the addn. of hydrated lime lightens the color of the concrete and that the initial set may be delayed for about $\frac{1}{4}$ hour by adding 10-20 lb. per bag of cement, allowing 12 bags to the ton. H. G.

The harmful effect of an excess of water on poured concrete. ORTHAUS. *Tonind.-Ztg.* 52, 2043-5, 2078-80(1928).—Proper tech. control is needed to design the mix to avoid the addn. of an excess of water in order to get the consistency required for concrete to run through troughs. F. O. A.

Rust removal from iron in concrete. P. MECKE. *Tonind.-Ztg.* 53, 27(1929).—Where a cement contg. slag is used for making concrete the rust is removed from the reinforcing iron under certain conditions. When the concrete is kept damp and out of contact with the air, sulfide from the slag reduces the rust to form the dark-colored iron sulfide. On coming in contact with the air this changes to compounds almost colorless. F. O. A.

Protective and waterproof coatings for concrete, mortar and stone. H. E. SCHUBERT. *Bauing* 9, 325(1928); *Building Sci. Abstracts* 1, 170(1928).—The author describes 9 proprietary compns. for coating the surface of concrete mortar or stonework to render it waterproof and weather resistant and the "Contex" process for surfacing concrete so as to expose the aggregate. H. G.

Experiments with Tricosal III. KLEINOGEL. Materialprüfungsamt, Berlin-Dahlem. *Beton Eisen* 28, 20-1(1929).—Tests showed the presence of this addn. agent increased the strength, the resistance to abrasion and to corrosive oils, as well as making the mortar denser. F. O. A.

Preparation of special limes from brown-coal ashes. HEINRICH LUFTSCHITZ. *Tonind.-Ztg.* 53, 64-5(1929).—On igniting coal ashes, after fine grinding, to 1200-1300°, F. obtained some products high in CaSO_4 and again a hydraulic lime. By igniting with

limestone, much of the SO_2 was reduced and portland cements were obtained having fair hydraulic properties.

Efflorescence: causes and the remedies. H. FENELON. *Carp. & Build.* 102, 1038, 1088-90(1928); *Building Sci. Abstracts* 1, 182.—Effects of efflorescences on stone, plaster and cement are discussed. The peeling of distemper off Keene's cement surfaces is not as much due to lack of adhesion, as to the wet rendering behind the cement, the alum in which is thus kept wet and prevents close adhesion between distemper and cement. The only remedy is to allow sufficient time for thorough drying of the wall. The failure of distempers is to be mainly attributed to the presence of salts in the mortar which cannot be reached by ordinary treatment with solns. A method for eliminating salt from sand by using HCl and AcOH is explained. Where the sand has not been thoroughly washed, and the rendering has already been done, the latter may be coated with a mixt. composed of alum and Fe sulfate.

Creosote treatment of timber. S. W. KEYS. *Facts about Sugar* 23, 1230-7 (1928).—K. reviews the methods and results of this treatment.

Thermo-conductivity and shrinkage of wood. A. HERMANN. *Timberman* 29, 51(1928); *Building Sci. Abstracts* 1, 178.—Rept. on expts. carried out on the thermal cond. of various woods, as related to their ds., indicates that the lighter the wt. of the wood the less is the heat transmission. Tests on shrinkage are also discussed. In ponderosa pine there is a shrinkage of 1 per cent in width with every 5 per cent variation in moisture content. Idaho white pine, sapwood and heartwood, each shows a shrinkage of approx. 1 per cent with every 4 per cent change in moisture content. The shrinkage ratio in both light and heavy boards of ponderosa pine is approx. equal but in Idaho white pine light boards shrink slightly more than do heavy boards. These tests are being continued and amplified.

The velocity of dehydration of gypsum at different temperatures (BUDNIKOV) 2. The velocity of dehydration of dry gypsum (BUDNIKOV) 2. Mixing "wood wool" and "soft cement" or other long fibered and powdery materials (U. S. pat. 1,698,881) 13. Swiss pat. 127,246) 18. Water gas, H_2PO_4 , and molten cement (Fr. pat. 639,412) 18. Granulating molten slag (U. S. pat. 1,699,575) 9. Determination of Fe and Al oxides, Mg oxide and Ca oxide in portland cement (PIERCE, SERZER) 7.

Cement. CELSO P. BACCOVICH. U. S. 1,696,899, Jan. 1. Acidic rocks such as granites, granulites, porphyries, syenites or pegmatites contg. a substantial quantity of alkali are crushed and dried at a temp. of 200-500°, reduced to an impalpable powder (finer than ordinary commercial portland cement) and then intimately mixed with portland cement contg. SiO_2 in preponderance over Al_2O_3 .

Cement. THOMAS RIGBY. U. S. 1,699,451, Jan. 15. Slurry is subjected to a heat treatment in an elongated cylindrical heated kiln inclined slightly to the horizontal and is supplied to the kiln in a plurality of streams from nozzles which are spaced from the intake end of the kiln; the kiln is rotated to effect passage of the material through it.

Cement. CHARLES E. KRAUS. Swiss 127,196, June 17, 1926. A mixt. of baked clay with CaO , $\text{Ca}(\text{OH})_2$, CaCO_3 or other Ca compd. is treated with H_2SO_4 to give a product contg. CaSO_4 , $\text{Al}_2(\text{SO}_4)_3$ and colloidal SiO_2 , and this product is mixed again with a Ca compd. It is preferred to use clay pretreated with NaOH soln. and to operate at 100-216°.

Cement. INTERNATIONAL CEMENT CORPORATION. Fr. 642,168, Oct. 11, 1927. Clinker of normal portland cement contg. or mixed with additional CaCO_3 sufficient to sat. the SiO_2 , Al_2O_3 and Fe is submitted to one or more bakings and ground after cooling. A retarder such as gypsum may be added before grinding. Cf. C. A. 22, 3031.

Portland cement. HARVEY R. DURBIN (to International Cement Corp.). U. S. 1,700,032, Jan. 22. A portland cement having a tensile strength of at least 240 lbs. per sq. in. at 24 hrs. with a 1:3 sand mixt. is prepd. by burning portland cement clinker comprising a large proportion of tri- Ca silicate together with incompletely lime-satd. silicate in intimate mixt. with lime in quantity not greater than that required to complete the satn. of the incompletely satd. silicate, and then grinding the product. U. S. 1,700,032 specifies a portland cement having a tensile strength in excess of 300 lbs. per sq. in. at 24 hrs. in a 1:3 sand mixt. and which is prepd. by using silica, alumina and iron with lime in quantity not more than theoretically necessary to sat. the silica, alumina and iron in one burning operation, burning to incipient fusion, grinding, re-burning to incipient fusion, and grinding the re-burned product. Cf. C. A. 22, 3031.

Slag cement. ANDRÉ CHARTIER. Fr. 641,753, Oct. 3, 1927. Granulated moist

slag from blast furnaces and quick or slaked lime are carried by sep. elevators to a mixer from which the mixt. is led to a rotating furnace and from thence to a grinder.

Waterproof cements. INTERNATIONAL PRECIPITATION CO. Brit. 291,988, Aug. 15, 1927. Portland or other hydraulic cements are mixed with a natural earthy material such as a shale, clay or diatomaceous earth contg. at least 5% of oil-sol. bituminous or oily material. The selected material may contain amorphous silica and other substances such as the chlorides, fluorides, sulfates, silicates or fluosilicates of Mg, Ca or Zn may be added.

Quick-setting cement mortar. RICHARD SCHNOBEL. Aust. 110,265, Mar. 15, 1928. Solns. of heavy metal oxides in alkalis, for instance $\text{Zn}(\text{ONa})_2$, are added to the cement mortar.

Concrete. F. W. McRAE (to Barber Asphalt Co.). Brit. 291,784, June 10, 1927. Material such as concrete, after being laid, and after the surface water has dried off, is sprayed or otherwise treated with an adherent waterproof coating, such as a soln. of asphalt and gilsonite in a petroleum distillate, to prevent further evapn. of water. This coating may also serve as an "anti-glare" coating on pavements. Cf. C. A. 22, 4757.

Concrete. ARTHUR C. KNIPE. Swiss 127,195, Apr. 22, 1927. The damp-mixing of the ingredients is effected under reduced pressure so as to free the mass from air. A suitable plant is described.

Pitch concrete. MARCEL LEVY (to "Prodor" fabrique de produits organiques soc. anon.). U. S. 1,699,705, Jan. 22. A pitch concrete with a mech. strength substantially equal to that of cement concrete is formed with a brittle pitch dried so as to remain hard at temps. of 80° together with an aggregate such as broken stone and fine powdered material such as limestone powder sufficient to form a thick pasty mass with the pitch. The pitch concrete thus formed is suitable for making conduits, etc. Cf. C. A. 22, 3756.

Manufacture of concrete blocks. HUGO APFELBECK. Austrian 110,270, Mar. 15, 1928. The steam pressure under which the blocks are hardened is caused to fall comparatively slowly.

Artificial stone. FRANZ GUNTER. Austrian 110,118, Oct. 15, 1928. In the manuf. of artificial stone from mineral fillers and water-insol. binders, particularly from limestone and asphalt, the binder is emulsified with an aqueous soln. of hexahydrobenzoic acid or its salts or with an alkali resinate, the filler is stirred in, and the emulsion is then broken by addn. of alk.-earth or heavy metal salts. The coagulate is sepd. and washed.

Artificial stone. KURT SCHENKEL. Ger. 468,780, Mar. 29, 1927. Addn. to Ger. 468,170 (C. A. 23, 684). In making porous artificial stone from gypsum or other water-solidified material as described in the prior patent, the hydraulic binding material is mixed with org. or inorg. colloidal soln. such as gelatin or glue.

Hardening lime. AKT. GES. DER VEREINIGTEN ASPHALT AND BAUMATERIALIEN-WERKE WIEN-FLORIDS DORF-WOPFING (Otto Grafes Nachf. N. Schefftel). Austrian 111,371, June 15, 1928. In the manuf. of objects of artificial stone by mixing an aq. soln. of $\text{Ca}(\text{OH})_2$ with fillers, etc., shaping, and hardening with CO_2 , the hardening is accelerated by adding to the initial mass substances, such as sugar, which combine with $\text{Ca}(\text{OH})_2$ and increase its soly. in water but are set free again by CO_2 . The objects may be heated to $60\text{--}80^\circ$ after hardening.

Road making. CARL ALEXANDER AGTHE. Swiss 127,731, May 4, 1927. Bituminous material contg. only a small quantity of C or other binding material and a small addn. of rubber or lignite tar is used.

Road-making composition. F. RASCHIG. Brit. 291,276, Oct. 20, 1927. Clay, water and bituminous material such as coal tar pitch or petroleum pitch are used together to form a hard mass which is emulsifiable with water. The ingredients may be mixed while heated to about $40\text{--}50^\circ$ and sand may be added.

Road-making composition. MINERAL A. G. BRIG. Swiss 127,189, Nov. 29, 1926. Petroleum asphalt thinned down with org. solvents such as crude benzine is mixed with granular fillers such as sand to form a powdery mass which is applied by rolling or stamping in the cold. Rubber, drying oils, and alk. earths may be included in the compn.

Bituminous road-making materials, etc. W. SCHROTH. Brit. 291,749, June 7, 1927. Tars or tar mixts. are used, the phenol content of which is higher than that of the high-temp. tars and lower than that of the low-temp. tars. The material is treated with oxidizing agents or S or both, as by boiling with injection of air, and contact substances may be added.

Making building material water-tight. A. A. BRYUSHKOV and P. I. SHABLUKIN. Russ. 4939, Mar. 31, 1928. Fatty soap solns. are added to mineral oils and mixed with prepd. mortar either straight or in the form of a water emulsion.

Composition shingles. ALBERT L. CLAPP (to Flintkote Co.). U. S. 1,698,886, Jan. 15. Asbestos fiber is beaten in water together with cellulosic fiber and a waterproofing material such as montan wax and gilsonite and a precipitable sizing such as in size is added, followed by addn. of a pptg. agent such as $Al_2(SO_4)_3$ and further beating after each of these addns.; the material is then run off on a paper machine, and is then fluxed and cut into shingles.

Apparatus for treating sheet roofing material with waterproofing substances. WILLIAM T. HOFMANN (to Flintkote Co.). U. S. 1,697,464, Jan. 1.

Impregnated roofing felt or similar material. ROBERT T. JOHNSTON (to Flintkote Co.). U. S. 1,698,886, Jan. 15. The material is passed through hot asphalt or other suitable impregnating substance at atm. pressure and after removal from the impregnating bath is subjected to a vacuum in order to remove air, moisture, etc. An app. is described.

Building slabs. S. MINACHE. Brit. 291,647, Aug. 20, 1927. The 2 outer layers of the 3-layer slab described in Brit. 213,495 (C. A. 18, 2416) are formed of $MgCl_2$, MgO and pulverulent waste material such as sawdust. The 3 layers are molded and pressed together and after setting are placed in water for a time.

"Wood substitute" comprising layers of artificial resin and pulp board united by heat and pressure. AGASOTE MILLBOARD CO. Brit. 291,633, July 12, 1927.

Construction material formed of fibrous and bituminous materials. RAY P. JERRY AND KENNETH B. HOWELL (to Barrett Co.). U. S. 1,698,733, Jan. 15. A material suitable for roofing or other uses is formed of layers of substantially uniformly distributed fibrous material and bituminous material rigid at ordinary atm. temp., softened by heat and pressure and having asbestos surfacing material adhering by action to the bituminous material.

Plastic bituminous product. MARK R. CONE (to Union Trust Co.). U. S. 1,698,877, Jan. 15. In forming a plastic mass suitable for use in roofing or paving, material such as asphalt or pitch is sprayed at a temp. above its m. p. to divide it into small particles and these are caused to solidify out of contact with each other, then immersed in heated water, gradually cooled at atm. temp. and the water is sepd. to obtain a moist plastic paste. U. S. 1,698,878 relates to a similar product.

Lined wallboard. OLIVER W. STOREY (to C. F. Burgess Laboratories). U. S. 1,698,851, Jan. 8. A mixt. of soap and Na silicate or other intumescent plastic and a liner such as $CaCO_3$ is heated while confined between paper facings to puff and solidify the mixt. and cause it to adhere to the facings and the edges of the board are closed during the heating to maintain a steam pressure upon the inner surfaces of the liners during the puffing operation.

Preparing sand molds. RUDOLF ULLMANN. Austrian 111,272, June 15, 1928. In preparing sand molds for use in forming *molding boards from MgO cement*, sand mixed with orax is used, and the upper surface of the mold is strongly heated.

Floor-covering material. CHARLES F. HUMPHREYS and JOHN C. MCCARTHY (to Armstrong Cork Co.). U. S. 1,697,426, Jan. 1. A sheet material of felt is impregnated with a plastic filling material such as a bituminous compn. and is provided with a colored pattern in relief.

Superficially coloring wood. MALCOLM SPARKES. U. S. 1,697,026, Jan. 1. The surface of Oregon pine or similar wood is first treated with a soln. contg. $FeSO_4$, moisture is evapd. from the surface and it is then treated with a soln. formed from $K_2Cr_2O_7$ mixed with an aq. soln. of NH_3 .

Preserving wood. L. P. CURTIN. Brit. 291,857, March 7, 1927. Wood may be impregnated with $Ba(OH)_2$ which is converted into $BaCO_3$ in the wood. Oil, Na_2CO_3 , etc., also may be used.

Wood-preserving composition. KARL H. WOLMAN. U. S. 1,700,010, Jan. 22. Dinitroresol, NaF, arsenates and alkali dichromates are used together. Cf. C. A. 22, 1026.

Preserving cellulosic material such as wood. LEO P. CURTIN (to Western Union Telegraph Co.). U. S. 1,698,622, Jan. 8. Material such as red cedar or Douglas fir is impregnated with an emulsion contg. a liquid hydrocarbon material, such as a petroleum oil and an aq. soln. formed from arsenious acid and NH_3 , which is capable of depositing free As_2O_3 upon exposure to the air.

Impregnating wood, etc. MORRIS SMITH. U. S. 1,699,635, Jan. 22. Wood or similar porous material is dried by the action of hot and humid air, impregnated with a softening agent preferably of oleaginous character such as an aq. Turkey-red oil emulsion or cod oil emulsion by use of a vacuum and the softening agent is then "vaporized"

at a relatively high temp. (suitably about 110–120° with cod oil emulsion) to cause it to penetrate the wood.

Impregnating and compressing wood. FELIX LAUTER (to Lignel Corp.). U. S. 1,697,248, Jan. 1. A liquid contg. an aldehyde, such as CH_3O or furfural, is used for impregnating pine or other wood and the latter is then heated under pressure to reduce its vol. and obtain a product suitable for furniture or elec. insulation. Phenolic compds. also may be used.

Method of impregnating wood. KARL BUBLA. Austrian 109,709, Jan. 15, 1928. The wood is treated first with a weak soln. of a suitable impregnating agent and then with a stronger soln. of the same agent, each treatment being applied at first under reduced pressure and later under increased pressure.

Apparatus for dyeing or impregnating tree trunk sections. FRANZ A. BRAUSIL. Austrian 109,990, Feb. 15, 1928. The app. is of the type in which the dyeing or impregnating liquid is forced through the trunk section in the direction of its length, and is designed to deal with sections differing widely in diam.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

Notes on recent developments in fuel technology. R. WIGGINTON. *Fuel Science Practice* 7, 469–71, 515–7(1928).—Brief reviews of: low-temp. carbonization at power stations, Japanese gas industry, coal classification, calorimetry of coke and clinker, and use of hot springs in Iceland.

Australian fuels: their industrial utilization and investigation. L. M. HIRCHBERG. *Chem. Fabrik* 1928, 619–20; cf. *Chem. Fabrik* 1928, 605.—Low-temp. distn. of lignites, prepn. of fuels to replace coal in locomotives, high-temp. distn. processes of lignites, coking of coal and lignite mixts., expts. on gas generators using Victoria lignite, and expts. with oil shales are reported in brief. A plant for treating coal by the Bergius process is to be operated near Melbourne. Opinions as to the best methods for treating Australian coals have not become unified; proposals for utilizing the fuel resources to best advantage are offered public and private support.

Auto-ignition temperatures of liquid fuels. OSCAR C. BRIDGEMAN AND CHARLES F. MARVIN, JR. *Ind. Eng. Chem.* 20, 1219–23(1928).—Data of more than 30 investigators of this problem are studied and correlated. Among the significant factors bearing on auto-ignition are (1) material and vol. of ignition vessel, (2) concn. of O_2 in mixt., (3) time lag before ignition, (4) pressure and (5) compn. of fuel. Recent work by the authors at the Bureau of Standards with a bomb of special design is discussed from these standpoints.

Five hundred tests of various coals in house-heating boilers. P. NICHOLLS, S. B. FLAGG AND C. E. AUGUSTINE. *Bur. Mines, Bull.* 276, 70 pp.(1928).—The av. over-all efficiency from all tests was 58% for an av. rate of output of 65,700 B. t. u./hr., equiv. to 262 sq. ft. of steam radiation. The hot-water boilers gave 3% higher efficiency than the steam boilers. The boiler having the larger grate, combustion space, and heating surface gave 4% higher efficiency. If the ash-pit loss is neglected, the efficiency of boiler and furnace shows a slow but const. increase from the subbituminous coal to the semianthracite, and the increase then becomes rapid. The av. over-all efficiency was independent of the calorific values of the coals. This can mean only that the combustible part burned as efficiently when associated with high as with low ash content. The dollar value of the coals depends upon the calorific value and is proportional to the calorific value multiplied by the over-all efficiency.

Coal washability tests as a guide to the economic limit of coal washing. GEORGE S. SCOTT. *Am. Inst. Mining Met. Eng., Tech. Publication No. 159*, 3–13(1929).—The highest economic purity of washed coal can be detd. from washability studies of the raw coal, costs of mining and washing coal, and data on the effect of ash and S on the value of the coal for the particular use for which it is intended. The numerous numerical data assumed, it is hoped, approach closely enough the av. working conditions to give some idea of the order of magnitude of the various economics evolved.

Heating value of coal in nickel-lined bombs. A. E. STROPPEL AND E. P. HARDING. *Ind. Eng. Chem.* 20, 1214–8(1928).—A method for detg. the amount of Ni dissolved in a Ni-lined bomb by the acids of combustion involves a titration of the bomb washings for free acid with Me-red indicator followed by a continuation of the titration in hot soln. with the same alkali using phenolphthalein. To correct for heat of corrosion

in coal tests a method is proposed involving titrations of the washings for free and for combined acids, and a knowledge of the S content of the coal. H. L. OLIN

Heat balance spots controllable losses. A. A. POTTER AND H. L. SOLBERG. *Purdue Univ. Power* 68, 1045-8(1928).—Heat losses consist of sensible heat carried away by flue gas, CO in flue gas, C in ash, heat required to evaporate H₂O of coal and to superheat H₂O of coal and air, combustion of H at temp. of flue gas and unclassified losses such as radiation, etc. Charts and equations are given from which these losses can be evaluated. D. B. DILL

The propagation of a zone of combustion in coal. V. 1. The effect of temperature. 2. Temperature of spontaneous propagation. S. H. JENKINS AND F. S. SINNATT. *Fuel Science Practice* 7, 556-62(1928).—Previous work (*C. A.* 22, 153) has shown that when coal is formed into a train of fixed dimensions, and one end of the train is heated momentarily, the combustion traverses the train of coal. The zone in which combustion proceeds is followed by observing the color change from the brown of the coal dust to the black of the oxidation product. On placing the train of coal dust in an oven at various temps. it was found that the rate of travel of the combustion zone increased as the oven temp. was raised. At 16° the rate was approx. 0.16 in. per min.; at 150°, 0.42 in. per min. After heating 10 min. at 210° the entire train burned spontaneously. When the coal was formed into a conical pile the heating originated within the pile. Packing of the particles together retarded the combustion. D. A. REYNOLDS

The hydrogenation and liquefaction of coal. V. The influence of composition, pressure, temperature and catalysts upon hydrogenation. D. G. SKINNER AND J. IVON GRAHAM. *Fuel Science Practice* 7, 543-55(1928).—Hydrogenation expts. were carried out in a large rotating autoclave, previously described (*C. A.* 19, 1188, 1767). The procedure has also been described (*C. A.* 21, 1175). A charge of 200 g. of 60-mesh (I. M. M.) coal, together with 100 g. of pure PhOH, was used in each expt. The products were sep'd. into: (a) PhOH-insol. residue; (b) PhOH-sol., CHCl₃-insol. powder; (c) PhOH-sol., CHCl₃-sol. liquid; (d) light spirit boiling below 150°; (e) water; (f) gases. Destructive-distn. tests at 450° were made for comparison, and the results of these tests show that, with most coals, there is a marked increase in oil production under the conditions of hydrogenation. The effect of catalysts was studied by using 5% of the oxide, or equiv. mixed intimately with the coal. Fe₂O₃ caused an increased oil yield of as much as 3% with some coals, the effect being the greatest with those coals otherwise giving moderate oil yields. Use of Fe₂O₃ on destructive distn. caused a decrease in oil yields, with one exception. Ni₂O₃ was a more effective catalyst; with one bituminous coal, products d and c were increased approx. 2.5 and 6.0%, resp., while products b and a were reduced 0.7 and 8.6%. Ni oxalate increased d 4%, c 9.0% and reduced b 3.7% and a 11.0%. NH₄ molybdate was the most effective catalyst, causing yields of 12.6% of d, 60% of c and only 5.5% of a. Hydrogenation of the residues of coal following extns. with PhOH and C₆H₅N shows that, with one coal at least, the PhOH-sol. constituents of coal are unattacked during hydrogenation whereas the greater portion of the C₆H₅N ext. is convertible to oil. Increasing the pressure from 155 atms. (that used as standard) to 245 atms. caused an increase of 5.3% of product c. Very fine grinding apparently favored the caking of coking coals, thus preventing the action of H. Product b was formed in quantities varying from 0.6 to 33%. It was in each case a brown powder of low sp. gr., contg. approx. 33% volatile matter. It melted between 260° and 310° and evolved oil between 320° and 340°. Rapid swelling attended its decompn.; the cokes thus formed were very fragile and exceedingly swollen. When b was mixed with the non-coking residue a, in the proportions in which produced by hydrogenation, and the mixt. coked, a very swollen coke was obtained. Product c was a viscous liquid with aromatic odor. It contained approx. 86% C, 7.5% H, 4% O, with less quantities of N and S. Generally 30% or less of c distd. below 300°. Unsaturated substances were found in the liquid, but not in the gaseous products. D. A. R.

Net hydrogen-volatile matter ratio in American coals and its use in producer-gas calculations. WILBERT J. HUFF. *Ind. Eng. Chem.* 20, 1371-2(1928).—The ratio carbon/(oxygen + ash) is not satisfactory for high-grade cannel, boghead, and similar coals when used as a basis for calcg. heating values. Such a method also disregards S. The equation of Diederichs, $H = V[7.35/(V + 10)] - 0.013$, and that of Seyler $H = a + b \log V$, where H is the % net hydrogen and V is the % volatile matter, have found extensive use. H. proposes the following formulas based on the work of Fieldner and Selvig (*C. A.* 13, 66): B. t. u. per lb. between 12,000 and 12,499, $H = 2.1 + 0.06 V$; B. t. u. between 12,500 and 14,499, $H = 3.95 \log_{10} V - 1.19$; B. t. u. per lb. over

14,500, $H = 0.42 + 3.2 \log_{10} V$, where H is the % net hydrogen and V is the % volatile matter. The correspondence between calcd. and exptl. values is within 0.2% of H . The use of the equations in producer-gas calcs. is illustrated by an example.

A. J. MONACK

A method of calculating pounds of air per pound of coal. W. H. MARTIN. Oregon State College. *Power* 68, 1059(1928).—The wt. ratio O/C is calcd. for flue gas from its compn. If one lb. of fuel contains a lbs. C, b lbs. H and c lbs. O, then wt. of air supplied per lb. of fuel = $[(O/C) a + 8b - c]/0.23$.

D. B. DILL

A partial dehydrogenation process for rendering certain hydrocarbons suitable for agglomeration of coal. ANDRÉ LÉAUTÉ AND GEORGES DUPONT. *J. usines gas* 52, 507-8(1928); cf. *C. A.* 22, 3761.—Application of the process to pitch was not successful.

F. S. GRANGER

The relationship between the specific gravity and ash contents of the coals of Korea and Bokaro: coals as colloid systems. L. LEIGH FERMOR. *Fuel Science Practice* 8, 16-29 (1928); cf. *C. A.* 22, 2452.—A definite empirical relationship between the ash contents and density of Korea coals is $a = 100(g - K)$; where K , the sp. gr. of pure ash-free bright coal equals 1.26, the ash contents (a) of other Korea coals of sp. gr. (g) were governed by this formula. This formula does not hold for carbonaceous substances contg. over 50% ash nor for certain coals that yield ashes of quite different chemical compn. The macroscopically homogeneous substances making up the majority of these coals are vitrain, durain, and micaceous carbonaceous shale. Fusain occurs infrequently in films.

D. H. REYNOLDS

The Bristol and Somerset coalfield: The carbonization of "Parkfield large gas" coal. C. H. LANDER, et al. Dept. Sci. Ind. Research. *Fuel Research* 1928, No. 12, 35 pp.—The purpose of the survey was to evaluate coals from the Somerset field with respect to their suitability for gas making. Tests were made in both vertical and horizontal retorts at high temps. as well as at low temps. Analytical data and logs of yields are given.

H. L. OLIN

Low-temperature carbonization at Dunston. ANON. *Ind. Chemist* 4, 473-7 (1928).—The purpose of the process is not to make domestic smokeless fuel, but to obtain certain liquid by-products from the coal without any additional charge for fuel for the generation of elec. power. Northumberland "rough slack" is screened to remove all below 0.25 in., preheated by chimney gases, and delivered to the retorts from which the coke is extracted by hydraulically operated toothed rollers. The fuel bed in the retorts is relatively shallow, and the coal requires about 3 hrs. to pass through the retort. The heating medium is a mixt. of hot gases and low-pressure steam, the former supplied by the combustion of fuel in a fire-brick chamber below each retort. The temp. in the retorts is adjusted to between 650° and 700° C. The rich gas from the top of the retorts is purified in the usual way, and the light oils are absorbed by wash oil. The through-put is about 100 tons per day. Illustrations, a diagram of one section of the plant and a flow-sheet are included.

E. G. R. ARDAGH

New observations on the origin of fusain. H. BODE. *Mitt. Abt. Geistes Kohle u. Sals. Untersuch.* 3, 12-22(1927); *Fuel Science Practice* 7, 487-92(1928); cf. *C. A.* 22, 2727.—A historical and critical review is given of many investigations of the origin of fusain. Fusain is a primary constituent of coal because of its proved existence in coal balls, in the sphaeroiderites of brown coals, and in primeval peat. While the theory of forest-fire formation is the only one which stands scientific criticism and is realizable experimentally, other theories must not be excluded.

D. A. REYNOLDS

Vitrain. M. M. EVANS, L. SLATER AND R. V. WHEELER. *Fuel Science Practice* 8, 30-6(1928).—Vitrain has been studied mainly with polished and etched surfaces viewed with incident light because transparent sections of this brittle substance are difficult to prep. All specimens of vitrain examd. in this manner have disclosed the appearance of plant cells, usually derived from cortical tissues; these plant cells are evidently pseudomorphs of the original structures. Vitrain is newly defined as a simple substance (as distinct from the aggregates, clarain and durain) consisting of ulmin compds. which have infilled plant cells and partly, if not entirely, replaced the materials of the cell walls, from which much of the ulmin material may have been derived *in situ*. Three main types of structures in British vitrains are: (1) parenchyma—thin-walled polygonal cells; (2) periderm—composed chiefly of sclerenchyma; (3) xylem—thick-walled cells of fragmented form. These structures are described and illustrated. The methods of polishing and etching specimens for microscopic examn. are described.

D. A. REYNOLDS

Refractory materials. Their uses in vertical retorts. A. T. GREEN. Derbyshire Silica Firebrick Co. *Gas World* 89, 554-7(1928).—A lecture.

F. S. GRANGER

Remarks on the operation of Woodall-Duckham continuous verticals at Lausanne. F. GILLIARD (in French) AND H. HAEMIG (in German). *Monats-Bull. schweiz. Ver. Gas u. Wasserfach.* 8, 317-26(1928). F. S. GRANGER

Recent developments in the production of motor fuels from coal. A. C. FIELDNER. *Fuel Science Practice* 7, 492-501(1928); cf. *C. A.* 23, 259.—A review of the production of motor fuel by: (1) the carbonization of coal, (2) the Bergius process and (3) the complete gasification of coal and conversion of the gases by pressure synthesis. F. believes the Bergius process, or some modification of it, will prove most economical. D. A. REYNOLDS

Motor alcohol. KAREL PETRLÍK. *Chem. Obzor* 3, 337-8(1928).—Dynalkol, the composition of which has been already given (*C. A.* 22, 3513) proved to be an ideal fuel in Czechoslovakia. JAROSLAV KUČERA

Distillation of peat. V. I. RAKOVSKII. *J. Chem. Ind. (Moscow)* 5, 915-9(1928).—If water vapor is injected into the retort in the course of distn. of peat, the distd. tar contains less asphaltenes than is the case in absence of a vapor current. Thus, in the former case the asphaltenic content is 1.5%, in the latter 5%. While F. Fischer (*Umwandlung der Kohle*, 97) expressed the opinion that this phenomenon is due to oxidation by water, R. does not believe that H_2O is the source of O combinations in the tar. The role of H_2O is rather that of impeding the condensation processes which normally take place with formation of water. BERNARD NELSON

Heat transfer in ammonia condensers. II. ALONZO P. KRATZ, HORACE J. MACINTYRE AND RICHARD E. GOULD. Univ. Ill. *Eng. Expt. Sta. Bull.* 186, 26 pp. (1928); cf. *C. A.* 22, 1228.—The condenser used was a 10-ton vertical shell-and-tube previously employed but modified by raising the level of the liquid or by blocking off a number of tubes, thus reducing its effective surface. By varying this surface it was found that the condenser tonnage per unit of surface is independent of the size or the proportion of the condenser and that it is a function only of the initial temp. of the water and of the amount circulated per unit of surface and time. The results confirm also the general principle that rate of heat transfer varies inversely with the thickness of film of liquid NH_3 on the tubes and directly with temp. gradient. Tests with superheat removers showed that the coeff. of superheated NH_3 to water was only one-eighth that of satd. NH_3 . H. L. OLIN

Waste-heat boilers conserve oil and make saving. S. H. GRAF. *Am. Gas J.* 129, 12-7(1928).—Waste-heat regenerative boilers at a Portland Oregon, gas plant return 10% on investment costs. H. L. OLIN

Cost of gas dehydration. G. A. BRAGG. *Am. Gas J.* 129, No. 6, 37-41(1928); cf. *C. A.* 22, 1670. Cost figures are given, based on studies made with different types of plants, viz (1) absorption with hygroscopic solus., (2) refrigeration and (3) compression. H. L. OLIN

Effect of carbon dioxide on plant economy. B. C. SPRAGUE. *Power* 69, 62(1929).—Changes in % CO_2 in boiler outlet gases should be considered in relation to temp. of outlet gases, temp. rise of water in economizer, temp. rise of air in air heater, temp. of superheated steam, combustible material in refuse of stoker-fired boilers and amt. of combustible gas in flue gas. D. B. DILL

Gas-producer theory and design. E. TERRES. *Gas Wasserfach* 71, 1205-13 (1928). Gas producers should be designed and operated to give max. H with minimum CO_2 . Charts are given for efficiency and air requirements for combustion with varying percentages of H and CO_2 . The ordinary diagram of CO_2 concn. at diff. points of the producer is erroneous. Actually the central part of the producer has the lowest CO_2 percentage (4.2% in one instance) and the highest (7.0%) near the walls. The av. CO_2 percentage can be reduced by proper design. For a fuel of a given size the efficiency of a producer increases with increasing height and diam. to max. values and then decreases. Diam. is also limited by difficulty in air distribution. The zone of high CO_2 at walls can be reduced by reducing radiation. Water cooling of walls increases CO_2 as much as 3-4%. Coke smaller than 2 mm. is likely to form "flying dust" and comprises 80% of that carried by the gas. Slight increases in diam. and height decrease dust in gas. Ash content of fuel has little effect on the amount of gas which a given producer can make, as higher ash content results in higher air temp. Details are given of the exptl. producer and the method of air distribution is illustrated. R. W. RYAN

Commercial possibilities in the use of synthetic hydrocarbon processes in the gas industry. W. W. ODELL. *Bur. Mines, Repts. Investigations* No. 2903, 15 pp. (1928).—Peak requirements demand available gas-generating app. which is idle a large part of the year. To care for irregular demand, as well as to insure independence of petroleum

products for enriching, it has been suggested that water-gas and synthetic hydrocarbon production be carried out together to give an enriched gas. During off-peak demand, liquid hydrocarbons could be prep'd. for motor fuels and for enriching requirements of future peak gas production. Sufficient data are not available to det. the applicability of this process; purification requirements are uncertain and the com. development of the proper type of catalyst has not been studied.

A. S. CARTER

Refractories in the gas industry. E. W. SMITH AND H. M. SPIERS. *Gas World* 89, 579-88; *Chemistry & Industry* 47, 1278-84(1928).—Raw materials and requirements, including constancy of volume, freedom from disintegration under temp. fluctuation, refractoriness under load, chem. stability, mech. strength, shape and texture, are discussed.

F. S. GRANGER

The regenerative complete gasification system. A. K. COLLINGE. *Gas World* 89, 557-60(1928).—The Preston plant is described. Also in *Gas*, J. 184, 673-6(1928).

F. S. GRANGER

Water gas from bituminous coal. J. GWOSDZ. *Gas Wasserfach* 71, 1233-9, 1253-9(1928).—A critical review of methods of producing water gas from bituminous coal, including American methods, especially the "back run" method, the production of low-gravity water gas, tar cracking, the new Winkler generators at Leuna Works, and complete gasification. The last method is suggested for stand-by equipment if gas is purchased from a super-gas system.

R. W. RYAN

The new Sulzer dry quenching installation at the municipal gas works at Schaffhouse, Switzerland. H. KAESER. *Directeur du Service. J. usines gaz* 52, 529-31(1928).—Operation and performance are described.

F. S. GRANGER

Detecting leaks in gas lines. HANS LÖFFLER. *Z. kompr. u. flüss. Gase Pressluft-Ind.* 27, 77-8(1928).—Illuminating-gas leaks can be readily detected by means of Strache's instrument, called the "Rapid" gas detector. The instrument operates by indicating the increase of pressure within a metallic bellows when the gas diffuses through a porous diaphragm forming one side of the bellows.

R. L. DODGE

New catalytic processes for the utilization of coal-tar crudes. A. O. JAEGER Selden Co., Pittsburgh. *Ind. Eng. Chem.* 20, 1330-5(1928).—One of the chief obstacles to the production of vat dyes derived from anthraquinone has been the difficulty of obtaining high-grade anthracene from the crude material. The processes usually employed for purification of crude anthracene are expensive and slow. Two basically different processes are described. (1) By selective catalytic oxidation at 360° to 440° in the vapor phase, the heterocyclic impurities, paraffin impurities and aliphatic compds including phenanthrene, may be burned out, yielding anthracene of high purity. The catalysts are metallic oxides "stabilized" by compds. of the alkali metals, alkaline earth metals and some earth metals that form difficultly reducible oxides. The purified anthracene may be condensed as such, or may, in the same operation, be passed directly through a second specific catalyst for direct air oxidation to anthraquinone. Zeolites contg. V_2O_5 as one of the amphoteric oxides are eminently adapted for this latter purpose. (2) If it is desirable to recover the carbazole impurity of the crude anthracene, a different method of purification is described, using furfural as a specific sepg. solvent for anthracene. The recovery of anthracene is about 96%. The product is usable for catalytic oxidation to anthraquinone. The phenanthrene and carbazole are recoverable from the mother liquor.

R. L. DODGE

The coal-tar phenols. HORST BRÜCKNER. *Tech. Hochschule, Dresden. Erdöl u. Teer* 4, 562-4, 580-3, 598-602(1928).—The first complete even qual. sepn. of the cresols and xylenols in coal tar has been accomplished quantitatively. Various methods and their limitations are reviewed. The decompn. of the sulfonic acids with superheated steam, yielding the original phenols (Raschig, *D. R. P.* 114,975 (1900)), previously applied only to *m*- and *p*-cresol, was used for the primary sepn. The phenols are heated with an equal wt. of H_2SO_4 (sp. gr. 1.84) for 3 hrs. at 103°. The product is dild. with several vols. of water and distd. As concn. progresses, the b. p. rises, and the temp. is held at each decompn. interval, until no more phenol passes over, by regulating the passage of steam through the mixt. For each phenol there was found to be a definite temp. interval at which its sulfonic acid decompd., namely, for phenol (I) 123-6°, *o*-cresol (II, III) 133-6°, *m*-cresol (IV) 116-9°, xyleneol 1, 2, 3 (V) 115-8°, 1, 2, 4 (VI) 11°, 1, 3, 2 (VII) 124-8°, 1, 3, 4 (VIII) 121-5°, 1, 3, 5 (IX) below 105°, 1, 2, 4 (X) 8°, *o*- or *p*-ethylphenol (XI, XII) below 105°, *m*- (XIII) 125-30°. Starting with individuals, the yields are 90 to 100%. The method was tried successfully first on synthetic mixts. and then on com. high-temp.-coal-tar cresol and xyleneol fractions. The sepn. was facilitated by first fractionating the mixts. and treating various fractions separately. In cases where 2 or more phenols were obtained within the same temp.

range, secondary sepn. by other methods were resorted to. IX was sepd. from XI and XII, and IV from V and X, by means of the *soly. of the Na phenoxides in 25% NaOH*, the salts of IX, V and X being only slightly and all of the others very sol. I was sepd. from VIII, and II from III, by the differences in *soly. of the Na phenoxycetates*, prepd. as below, VIII and II giving easily sol. and I and III only slightly sol. salts. XI and XII may be sepd. as Ba salts of their sulfonic acids (Scmpotowski, *Ber.* 22, 2674 (1889)). The sepn. of X from V was effected only qualitatively, by means of the slight *soly. of the sulfonic acid of X in 50% H₂SO₄* (Ges. f. Teerverwertung, Duisberg-Meiderich, *D. R. P.* 447,540). VII, owing to its very weak acidic properties, is not extd. in considerable quantity by the usual NaOH treatment and so is not likely to be found in tar phenols. Good yields, usually about 80%, were obtained in most cases, and the identities of the products were confirmed by the mixt. m. p. method, applied to the phenoxycetic acids. For the prepn. of these, Glud and Breuer's method (*C. A.* 14, 938, 1432) was found unsuitable. The method of Steinkopf and Höpner (*C. A.* 20, 2905) proved satisfactory when modified as follows. Ten g. of the phenol, in a 100-cc. Erlenmeyer, is stirred intimately with 2.5 equivs. of finely powd. NaOH until the heat liberated is dissipated. Ten g. of ClCH₂COOH is then stirred in, an air condenser is attached at once and the flask is well shaken. The reaction is completed in about 2 mins. The product is dissolved in water, pptd. as free acid by HCl, dissolved in ether and extd. as pure Na salt by Na₂CO₃ soln. IX was obtained in such a pure state, in the steam distn. of the sulfonated crude tar-xlenol mixt., that it crystd. even in the condenser. In the tar products, the cresols were found in the proportions, ortho 35%, meta 37% and para 28%, and the xlenols, VI 18.1%, VIII 11.1%, IX 36.6% and V + X 21.4%. VII and the ethylphenols were absent. The sepn. of *m*-cresol, from the other cresols, as the trinitro deriv., by the method of Raschig (*Z. angew. Chem.* 13, 759 (1900)), in which the other cresols are destructively oxidized, was found inapplicable in the presence of either phenol or xlenols, because of the formation of cryst. di- and trinitro derivs. with the former and resinous products with the latter.

F. S. GRANGER

The "e-phenols" of primary tar. G. VAVON AND N. ZAHARIA. *Inst. de chimie de Nancy J. usines gaz* 52, 534 7(1928).—It is shown experimentally that phenols in general are extd. from their aq. phenolate solns. by org. solvents, because of hydrolysis, and that the % of total phenol extd. increases with the *soly. of the phenol in the solvent used* and with the relative vol. of the solvent, and decreases with increasing concn. of the aq. soln. or excess of alkali. At very high concns., however, aq. phenolate solns. become miscible with ether, leaving only a small aq. layer, contg. only free alkali liberated by hydrolysis. Phenol itself is hydrolyzed much less than any of the large no. of homologs tried. The degree of hydrolysis, or % extd., is decidedly greater with the ortho derivs. and increases with the no. and size of the side chains. These facts are presented in explanation of the results of Weindel (*C. A.* 19, 3368), who extd. primary tar phenolate solns. with ether and considered the phenols so extd. to belong to a different class, which he designated as "e-phenols."

F. S. GRANGER

Fire protection of tar operations with special reference to extinguishing methods using foam. VON BEZOLD. *Teer u. Bitumen* 26, 613 7(1928).—A general discussion.

F. S. GRANGER

Water instead of mercury in the Kraemer-Sarnow method. TH. HEYDECKE. *Teer u. Bitumen* 26, 567-8(1928).—Water can be substituted if the softening point of pitch is not over 90°, thus avoiding the danger of Hg poisoning. Exact agreement between the 2 methods was obtained on a variety of samples. The accuracy was improved by inserting a loose wad on top of the pitch, to hinder the chilling effect of the slightly cooler exposed water.

F. S. GRANGER

A further study of coke formation. R. A. MOTT AND T. SHIMMURA. *Fuel Science Practice* 7, 472 86(1928); cf. *C. A.* 21, 1700. —Fourteen coals, 9 "brights" and 5 "hards" from the Yorkshire and Derbyshire collieries were used. The C content (pure coal basis) of the hards ranged from 82.1 to 85.2%. Both lump and powd. samples were heated in N to 900° at rates of 1° and 5° per min. At the slower rate, the swelling was roughly proportional to the C content. Swelling was not found to be due to rate of gas evolution during the plastic state. By carbonizing coals preheated, 390° to 450°, both before and after ether extn. of the preheated coals, it was shown that removal of these ether sol. oils causes marked decrease in the coke strength. It is suggested that the first stage of coke formation from crushed coal is the liquation of oil to the surfaces of the coal particles until these are completely wetted, and the second stage is the loss of identity of the coal particles with the formation of pore structure due to swelling. Numerous photographs of the cokes produced are included.

D. A. REYNOLDS

The grinding of coke for analysis. J. HILKS AND R. A. MOTT. *Fuel Science*

Practice 7, 509-11(1928).—The ashes were analyzed from several cokes pulverized by 5 methods: (1) agate mortar and pestle, (2) Mn-steel mortar, (3) Wedgewood mortar, (4) iron mill and (5) iron bucking board. The results show that the use of the Mn-steel mortar does not introduce an error such as may be caused by contamination on grinding by methods 3, 4 and 5.

The coking industry in Hokkaido. MASANA KAWAGUCHI. *J. Fuel Soc. (Japan)* 7, 1093-7(1928).—A review.

THIEMANN, A. E.: Kraftstoffe, Verbrennung und Schweröl-Vergasermotoren. Berlin: R. C. Schmidt & Co. M. 15.50. Reviewed in *Engineering* 126, 766(1928).

Fuel. THE CARBOCITE CO. Fr. 641,110, Aug. 3, 1927. A smokeless fuel is made by forming into balls in a rotating retort residues while still plastic from the distn at low temp. of very volatile coals.

Fuel. TRENT PROCESS CORP. Fr. 640,324, Aug. 31, 1927. Finely divided coal is heated with oil under pressure until soln. takes place.

Liquid fuel. GRANT HAMMOND (to Fuel Development Corp.). U. S. 1,699,355, Jan. 15. In prepg. a fuel suitable for use in automobile engines commercial gasoline is treated with a small quantity of a water-sol. alc. such as $EtOH$ and the mixt. is heated in a closed retort to produce a pressure of about 25 lbs. per sq. in., then cooled to normal atm. temp. and pressure and the mixed alc. and hydrocarbon is then decanted.

Liquid fuel. HANS HERZOG-IN ALBON and W. HÜSSY-BÜHLER. Swiss 127,555, Mar. 8, 1927. Motor fuel consists of petroleum and alc. in the proportion 9:1, which is led over a catalyst such as fused Pb or unslaked lime. Cf. C. A. 22, 1229.

Fuel and air supply apparatus for burning finely divided fuels. JOSEPH MOLZ (to Babcock & Wilcox Co.). U. S. 1,698,555, Jan. 8. A stream of fuel is projected downwardly into a conical space in the upper part of a combustion chamber to which air is supplied tangentially below the fuel inlet.

Fuel blocks. H. V. T. MILLS and V. D'O. NOBLE. Brit. 291,958, Aug. 8, 1927. Small coal is mixed with cement, sawdust and creosote.

Distilling fuel. HENRI DE LIPKOWSKI and PIERRE-JUSTIN-PAUL FUSIER. Fr. 640,940, Sept. 1, 1927. A distn. furnace has one combustion chamber in which individual furnaces contg. the fuel to be distd. are disposed in series so that combustion and distn. are propagated from one end to the other so that the distn. as a whole is continuous. Alternately the individual furnaces are movably mounted on a movable frame.

Distilling fuel. HARALD NIELSEN and BRYAN LAING. Fr. 640,451, Sept. 5, 1927. See Brit. 287,381 (C. A. 23, 503).

Distillation of fuels. PAUL GUSTAVE GRENF. Fr. 33,079, Sept. 24, 1926. Addn. to 629,406. The vapors from the distn. of solid fuels are treated in the presence of a catalyst on a base of active C as described in Fr. 629,406 for liquid fuels.

Distillation of solid fuel. MISTISLAV KULZINSKI. Fr. 642,046, Oct. 6, 1927. The fuel is placed in a tunnel-still in layers permeable to gas and is moved from one end of the tunnel to the other, during which it is heated with superheated steam mixed with gases and vapors from bitumen and oil. The steam, etc., passes transversely through the layer several times and at the same time is moved longitudinally in the tunnel, being reheated after each passage.

Distilling solid fuels of coking character. H. NIELSEN and B. LAING. Brit. 292,060, Dec. 4, 1926. The material treated is subjected to the action of hot gases contg. a controlled quantity of O (2-8%) or an oxidizing constituent to oxidize some

of the coking constituents and influence their coking power and, after carbonization, the solid residue is treated with steam to effect gasification. Carbonizing may be effected at 600° or lower, followed by a high-temp. treatment up to 1200°. A free-burning residue is obtained, which is not coated with graphitic C and is easily oxidized by the O of ores such as oxides of Cu or Fe or by steam in a water-gas producer. Various details are given.

Gasifying bituminous fuels. ALBERT BREISIG. Austrian 110,369, Mar. 15, 1928. Addn. to 107,421. The method of Austrian 107,421 (see Austrian 109,169, C. A. 22, 4778) is modified by circulating the gases through the accumulators without preliminary sepn. of tar.

Agglomerating powdered fuel. AURÉLE LOUIS JOSEPH VOINCHET and ACHILLE ARMAND LERCIU. Fr. 641,137, Sept. 14, 1927. Kaolin or Al silicates and silicates of Na or K are added to powd. coal and the mixt. is pressed and treated with a soln. of an alk. earth salt, e. g., CaCl₂.

Process and plant for burning powdered fuel. ÉMIL BARTHELMESS. Swiss 127,483, Mar. 21, 1927. The fuel is fed to a furnace directly from a crushing mill and the feed is regulated by feeding addnl. fuel from a storage receptacle arranged between the mill and the furnace.

Oven for heat-treating, coking or partly distilling fuel. OTTO HELLMANN. Ger. 467,845, June 9, 1926.

Fuel for gas engines. DEUTSCHE ERDÖL A.-G. Ger. 468,500, Feb. 12, 1925. Fuel for gas engines, particularly suction gas engines, is prepd. from semi-coke obtained by the low-temp. distn. of compressed bituminous materials, such as lignite, coal, shale or peat, the semi-coke having a moisture content not exceeding about 15% by wt. and being so subdivided that at least 90% is in granules of less than 5 mm. diam.

Coal containing less than 2% of ash. SOCIÉTÉ ANON. D'OUGRÉE MARIHAYE. Fr. 640,925, Aug. 9, 1927. After the usual flotation treatment with a soln. of ZnCl₂ to obtain a coal having 3–5% ash, the latter is again treated with a liquid of lower density to obtain a coal having less than 2% of ash.

Apparatus for sorting anthracite. A. A. LOTOTZKII. Russ. 4831, Mar. 31, 1928. Mech. device.

Disintegrator for preparing coal dust. N. I. GRIGORIEV and P. I. GRIGORIEV. Russ. 4860, Mar. 31, 1928. The app. is heated with steam and the gases and moisture from the coal are carried off by a blower.

Oven for drying coal. G. A. ARONS. Russ. 5054, Apr. 30, 1928.

Treatment of coal, peat, schist, etc. THOMAS D. KELLY. Fr. 642,310, Aug. 22, 1927. Coal, etc., is heated to 70–300° with an alk. soln. of Na, K or NH₄ oleate and Al₂(SO₄)₃ is added to solidify the oleate. The solid material is sepd. and molded or used as a pigment or mixed with rubber or polymerized oils. It may be distd. with water or steam to form a gas or can be used as a fuel. The liquid products may be fractionally distd. or used for making waterproof dressings or on roads.

Heat treatment of coal, mineral oils, etc. I. G. FARBENIND. A.-G. Fr. 641,344, Sept. 23, 1927. Coal, tar, mineral oils or their products of distn. as well as carbonaceous material of animal or vegetable origin which is to be submitted to a high temp. under pressure, e. g., for hydrogenation, are given a preliminary treatment in a vessel the walls of which form an elec. resistance and are heated by an elec. current. The vessel may be a straight or a serpentine tube. The material enters the heating chambers from the tubes, and the walls of the chambers may be heated in the same way.

Carbonizing finely divided coal or similar fuel. SAMUEL MCFEWEEN (to International Coal Carbonization Co.). U. S. reissues 17, 181–2, Jan. 1. See original pat. 1,481,140, issued Jan. 15, 1924 (C. A. 18, 895).

Carbonizing coal. COMPAGNIE HOUILLERE DE BESSEGES. Brit. 291,341, May 27, 1927. Non-caking or anthracite fines are agglomerated with about 5% of tar, pitch or a phalt, and briquets formed of this mixt. are suddenly heated to 700° or a higher temp. to form an "artificial anthracite" and a gas rich in H. Semi-coke obtained by low-temp. carbonization of coal may be similarly treated.

Carbonizing coal. WALTER RUNGE (to The International Combustion Engineering Corp., to the International Coal Carbonization Co.). Can. 285,723, Dec. 18, 1928. Pulverized coal is fed into the top of a vertical retort, the upper portion of which is cooled and the lower portion heated, and there is introduced into the retort at a point near the bottom a combustible gas whose temp. is approx. 1500° F. and at a point approx. midway a combustible gas whose temp. is such that when mixed with the gases rising from the bottom of the retort the resulting temp. is below the dew point of the vapors. The coal is caused to pass counter to the upwardly rising gases in such a manner that

it loses a large part of its volatile hydrocarbon content in the form of gases and vapors. The condensable vapors are condensed in the upper part of the retort and returned to the bottom portion for a second heat treatment. The coke and gases produced are removed and collected. Cf. *C. A.* 23, 691.

Heating and carbonizing powdered coal. W. E. TRENT (to Trent Process Corp.). Brit. 291,062, Oct. 25, 1926. Powdered coal or similar material is heated and carbonized by utilizing the heat obtained by the exothermic reaction which occurs during the heat treatment. Hot waste gases from a boiler plant may be utilized to distil powdered coal and the residue of the coal may be gasified in a producer and the gas employed to heat the boiler. The gases and vapors generated during the heat treatment of the powdered coal travel with the particles of the latter and serve to assist in agitating and conveying it and to heat it slowly to its fusion temp. and prevent agglomeration during carbonization.

Low-temperature carbonization of coal. M. J. McQUADE. Brit. 291,962, June 14, 1927. Coal is moved through a retort by forward movements alternating with backward movements of lesser extent, to facilitate escape of volatile matter into the space above the charge by agitation of the fuel. An app. is described comprising a horizontal retort contg. a screw conveyor which is periodically reversed.

Apparatus for low-temperature carbonization of coal or similar materials. FRANZ PUENING. U. S. 1,698,349, Jan. 8. Solid heat-transfer bodies such as iron balls or cubes are heated outside of a distn. chamber to a sufficient temp. to impart heat to a charge in the distn. chamber and are then introduced into the latter to effect distn. and carbonization of the material under treatment.

Distilling coal, etc. T. A. GOSKAR. Brit. 291,836, March 1, 1927. Finely divided caking coal and a binder consisting of a solid hydrocarbon of the paraffin or terpene series, bitumen, resin, etc., are intimately mixed and finely ground coal waste, anthracite duff, coke breeze or the like is added, and the mixt., preferably after being formed into briquets, is distd. The material may be fed continuously to the distn. retort and the latter may be supplied with producer gas, water gas or superheated steam and may be externally heated. Various details are given.

Distilling coal in a continuous tunnel kiln. PHILIP D'H. DRESSLER (to American Dressler Tunnel Kilns, Inc.). U. S. 1,698,493, Jan. 8. Coal is passed through the kiln passageway and heat is transmitted to the coal by circulating the kiln. atm. through a space partially sepd. from the passageway and in which the circulating atm. is heated and mixed with a decarbonizing fluid such as steam before being returned to the passageway. Various details of app. are described.

Low-temperature distillation of bituminous coal. RICHARD H. CARR and CORNELIUS B. WATSON (to Pure Oil Co.). U. S. 1,698,907, Jan. 15. In effecting coking and low-temp. distn. without active combustion, a body of the fuel is forced upwardly through a closed receptacle into the upper part of which is introduced a gaseous heating medium comprising superheated steam under temp. conditions which suffice to coke the fuel body in the upper portion of the receptacle without combustion; a portion of the primary distn. products is removed from the fuel body at a point between the fuel inlet and the coke outlet and these products of distn. are caused to traverse the fuel body in a direction counter-current to the direction of travel of the fuel body prior to the release of the distn. products from the receptacle. An app. is described.

Distilling coal or other solid carbonaceous materials. FRANZ PUENING. U. S. 1,698,345, Jan. 8. The entire distn. is effected by use of heat stored in solid heat-storing bodies such as iron balls which are brought into contact with the material undergoing distn. after they have been previously heated. An app. is described.

Distilling coal, peat, shale, lignite or other solid carbonaceous materials. FRANZ PUENING. U. S. 1,698,346, Jan. 8. Heat effective for causing carbonization is stored in vertical parallel spaced plates which may be formed of iron and preliminarily heated by hot gases and the material to be carbonized is then fed into the spaces between these heated plates and is carbonized by the heat previously stored in them. Various details of construction are described.

Distilling coal, lignite, shale, peat or other carbonaceous materials. FRANZ PUENING. U. S. 1,698,240, Jan. 8. The material is charged into spaces between relatively movable heating walls which may be formed of iron and after the distn. is effected the walls are moved apart to widen the space between them and facilitate discharge of the residue and are then returned to their original spacing. Various structural details are described.

Apparatus for distilling coal or other carbonaceous materials. FRANZ PUENING. U. S. 1,698,348, Jan. 8. Heating walls are carried by relatively movable supports pro-

vided with cooling channels and various details of construction of these and other features of the app. are specified.

Destructive hydrogenation. KOHLENVEREDLUNG A.-G. Brit. 291,481, Jan. 20, 1927. Solid bituminous substances, fuel and the like, are simultaneously distd. and hydrogenated in suspension in a stream of heating gas which may either be itself a hydrogenating agent or into which H or a H-supplying substance is admixed. CaH_2 , NaH, formic acid, H, steam and water gas may be used for effecting the hydrogenation.

"Smokeless fuel" from coal, lignite, etc. ILLINOIS ANTHRACITE CORP. Brit. 291,206, April 26, 1927. Coal, lignite or similar material is continuously passed through a retort or gas producer at a "comparatively fast" rate while maintaining a shallow bed of fuel which is continuously agitated to prevent sticking; heat is generated by restricted combustion so that only a part of the volatile matter is consumed and substantially none of the fixed C. The residue may contain about 12% volatile matter. An app. is described.

Rotary retort construction for distilling shale, coal, peat, etc. G. MENELL. Brit. 291,550, March 17, 1927.

Working coal-dust furnaces for steam boilers with superheater attached. ALLGEMEINE ELEKTRIZITÄTS-GES. (Friedrich Reinhardt, inventor). Ger. 469,370, May 8, 1925. To raise the temp. in the superheater, the hot gases from the fire space are mixed with waste gases from other furnaces in such amts. that the required temp. can be maintained.

Protecting furnace masonry, especially in coal-dust furnaces. ALLGEMEINE ELEKTRIZITÄTS-GES. (Günter Schimmelpfennig, inventor). Ger. 469,369, Mar. 29, 1924. To prevent damage as the result of large temp. differences, the hot fire gases are circulated around the masonry.

Regulating combustion furnaces. ASKANIA-WERKE A.-G. (formerly Centralwerkstatt-Dessau). Fr. 641,321, Sept. 22, 1927. An instrument is influenced by the compn. of the flue gases, e. g., their content of CO or CO_2 or their sp. gr. in such a way as to control the addn. of fuel to the furnaces.

Device for preventing rise of pressure in flues. MAX SOELLNER. Austrian 111,318, June 15, 1928. The waste gases are led obliquely into and out of an enlargement in the flue, etc.

Separating fibers from peat. GES. FÜR MASCHINELLE DRUCKENTWÄSSERUNG M. B. H. Ger. 469,603, Apr. 20, 1927. The peat is dewatered by simple pressing and is then mech. disintegrated to such an extent that the fibers can be sepd. by sifting. The making of briquets is thus facilitated.

Dewatering peat. JOSEPH HORST, MARIA GRAUL NÉE HORST, KATHARINA BREHM NÉE HORST, NIKOLAUS PETER HORST, FRANZISKA GERTRUD HORST, JOSEPH HORST and HEINRICH HORST. Ger. 468,566, Jan. 25, 1927. In dewatering peat by adding auxiliary substances such as dry peat and pressing in a no. of stages, the stages comprise a preliminary pressing ending at a relatively low pressure and a final pressing ending at a relatively high pressure and, between these stages, a repiling or rearrangement of the peat, with or without subdivision.

Dewatering peat. JOSEPH HORST, MARIA GRAUL NÉE HORST, KATHARINA BREHM NÉE HORST, NIKOLAUS PETER HORST, FRANZISKA GERTRUD HORST, JOSEPH HORST, and HEINRICH HORST. Ger. 468,565, Oct. 10, 1926. Peat or like material is dewatered in presses of known kind to such an extent that it can be further dewatered in band presses, that is, presses with two wedge-shaped, oppositely moving bands, without the application of additional pressure.

Drying peat and the like. HEINZ DICKMANN. Swiss 127,173, Feb. 16, 1928. Addn. to 124,804. In drying blocks of peat and like fuels by passing air around the suitably arranged blocks, psychrophilic and thermophilic microorganisms are added before forming the blocks so that fermentation is set up as the drying proceeds, the heat of fermentation assisting the drying. The material may be warmed to initiate fermentation.

Hydrolyzing peat. N. A. ELMANOVICH. Russ. 5062, Apr. 30, 1928. Peat is hydrolyzed by fermentation with yeast at a pressure above 6 atm. without the addition of acids but only by the acids contained in, and formed by the decompn. of peat.

Peat-briquetting machine. M. A. NARMIN. Russ. 3564, Sept. 15, 1924.

Apparatus (retort) for obtaining carbon from peat and sawdust. S. S. KUTZEV. Russ. 3800, Sept. 15, 1924. The fuel charged into a revolving retort is heated and the C and gas are withdrawn continuously into a container, where the gas is withdrawn through the top and the C through the bottom after being sprayed with water.

Underblast-traveling-grate peat furnace with drying and smoldering shaft. TICHON MAKARIEFF. Ger. 469,314, Nov. 16, 1922. Details of construction.

Apparatus (with a perforated revolving drum) for drying lignite or other combustible materials. HANSEN EVESMITH. U. S. 1,697,268, Jan. 1.

Distillation of lignites. ALEXANDRE FOLLIET. Fr. 642,518, Oct. 18, 1927. Lignite descends on a rotating helicoidal hearth in a thin layer and meets a current of combustible gases heated to 400–700°.

Purifying fuel gases. C. COOPER. Brit. 291,832, Feb. 11, 1927. Fuel gas is first treated with water-absorbing material to reduce its moisture content and is then treated with liquid oil to remove $C_{10}H_8$. An app. is described.

Gases for hydrogenation. FRIEDRICH BERGIUS. U. S. 1,699,177, Jan. 15. Waste hydrogenation gas such as that from the hydrogenation of coal is subjected to steam treatment in 2 successive stages at different temps.; in the first stage the higher temp. is used (suitably about 1100°) which is sufficiently high to decompose CH_4 in the absence of a catalyzer and to cause formation of CO and H_2 ; the second stage may be effected at a temp. of about 300–500° in the presence of a catalyzer such as Fe oxide adapted to enhance the reaction between CO and steam. An arrangement of app. is described.

Sampling furnace gases. SIEMENS & HALSKE A.-G. Ger. 469,404, Oct. 17, 1926. A vertical sampling tube passing through the furnace wall is surrounded for the greater part of its length by a closed vessel contg. a liquid heated by the furnace gases; condensation of water, etc., in the tube is thus prevented.

Producer gas. KARL KOLLER. U. S. 1,697,920, Jan. 8. In effecting total gasification of coal in a producer having a distn. and a gasifying zone, regulated quantities of mixed air, steam and CO_2 are admitted to the gasification zone to generate producer gas, the hot producer gas is passed through the distg. zone to distil and gasify coal in that zone and simultaneously a limited and regulated supply of O is introduced directly into the distg. zone to oxidize colloidal constituents of the coal and prevent caking in the distg. zone. An app. is described.

Gas producer. FERNAND FURET. Fr. 641,034, Sept. 16, 1927.

Gas producer. JEAN LOUIS PIERSON. Fr. 641,445, Aug. 29, 1927. $C_{10}H_8$ or the like hydrocarbon is introduced along with the steam into gas producers, producing C_2H_2 principally.

Gas producer. I. G. FARBERIND. A.-G. Fr. 642,315, Aug. 30, 1927. A gas producer using powdered fuel comprises a cylindrical chamber with horizontal axis. The fuel and gasifying agents are introduced tangentially, preferably at several points of its circumference so that the mixt. is given a rotating movement, and the gases leave the chamber at the center of one of the side faces. Cf. C. A. 22, 2830.

Gas producers. SOCIÉTÉ ANON. DES APPAREILS DE MANUTENTION ET FOURS STEIN. Fr. 641,903, Mar. 12, 1927. A leveling arm and automatic feed for the fuel are described.

Gas producer using wood. S. I. DEKALENKOV. Russ. 4615, Feb. 29, 1928.

Gas producers and furnaces. FRANÇOIS SCHWALLER. Fr. 641,904, Mar. 12, 1927. The hearth is constructed with rotatable bars.

Combined tubular boiler and gas producer. JULIUS PINTSCH A.-G. Ger. 468,481, Mar. 4, 1926. In a gas producer of the kind having vertical water-tubes arranged in its shell, the tubes are set in bundles and sep. collecting and delivering vessels are provided for each bundle.

Apparatus for mixing coal and tar and producing gas from the mixture. HARRY F. SMITH (to Gas Research Co.). U. S. 1,699,166, Jan. 15.

Water-jacketed furnace or gas-producer construction. STETTINER CHAMOTTE FABRIK A.-G. VORM. DIDIER AND E. TERRES. Brit. 292,052, March 1, 1927.

Water-gas generator construction. OWEN B. EVANS (to Ira C. Copley). U. S. 1,699,231, Jan. 15. A solid bridge structure is spaced below the top of the generator shell and above the grate providing radial vertical walls within the shell.

Arrangement for the automatic periodic reversal of the valve of a water-gas producer. PIERRE PLANTINGA. Ger. 469,086, May 16, 1924. Details of the device.

Plant for producing and carbureting water-gas. DEUTSCHE KOKSGAS G. M. B. H. Ger. 468,635, Mar. 6, 1924. In plant of the kind in which a superheater is superposed on the gas-producer and in which the carbureting agent is sprayed into the free space between the superheater and the upper surface of the fuel, the inlet for the carbureting medium is placed sufficiently far from the fuel surface to prevent the liquid medium from reaching the fuel.

Apparatus for generating gas for burners from fuels such as oil. WILLIAM C. SCHEU (to Harrison, Paul, Scheu Co.). U. S. 1,697,781, Jan. 1.

Apparatus (with a tangential air supply) for producing gas from finely divided carbon fuels. GEORGE L. REICHELTM (to Gasifier Co.). U. S. 1,699,543, Jan. 22. Structural features.

Gas carbureter. S. M. GLÄICHENHAUS. Russ. 4741, Feb. 29, 1928. Gasoline is placed in the lower part of a gasometer which has trays with wooden shavings. The gasoline is pumped into the upper part and the air through the gasoline layer in the lower part.

Ammonia and ammonium compounds from distillation gases. FIRMA CARL STILL. Ger. 469,003, June 24, 1923. The gases are cooled and the cloud of condensed NH_3 compds. is extd. by washing above the dew point of the gas in a jet app.

Desulfurizing gases. SINDICAT D'ÉTUDES DES MATIÈRES ORGANIQUES. Fr. 642,695, Feb. 8, 1927. Gases to be freed from S compds. are led through 2 or more purifiers, heated to about 250° , the first contg. oxides of Ni to remove inorg. S compds., the second contg. oxides of Cu, Fe or other suitable metal to remove org. S compds. and, if the gas contains water vapor, through a third contg. oxides of Ni to remove any H_2S formed in the second. The purifiers are in duplicate so that one set is being regenerated while the other is in use.

Removing sulfur compounds from gases. THE SILICA GEL CORPORATION. Fr. 641,695, Sept. 30, 1927. See Brit. 280,947 (C. A. 22, 3519).

Recovery of sulfuric acid. CARL STILL. Fr. 641,460, Sept. 13, 1927. H_2SO_4 used in the purification of benzene is recovered by mixing it with a concd. aq. soln. of $(\text{NH}_4)_2\text{SO}_4$ and heating until the resin acids sep. as a tar. The purified mixt. may be sent to NH_3 saturators.

Device for continuous filtration of benzine. KARL KIEFER. Austrian 109,838, Jan. 15, 1928. Constructional improvements are described in app. of the type in which a filter is fitted in the ascension pipe of a container from which the benzene is forced by compressed air.

Bleaching montan wax. WILHELM PUNGS and THEODOR HELLTHALER (to I. G. Farbenind. A.-G.). U. S. 1,698,450, Jan. 8. Montan wax is exposed to anodic action of an elec. current while finely divided in an electrolyte such as H_2SO_4 in the presence of an O transferer such as Cr sulfate.

Bleaching montan wax with chromic acid in the presence of acetic acid or other organic acids. WILHELM PUNGS (to I. G. Farbenind. A.-G.). U. S. 1,699,250, Jan. 15. Can. 285,712, Dec. 18, 1928.

Montan wax. WILHELM PUNGS and MICHEL JAHRSTORFER (to I. G. Farbenind. A.-G.). Can. 285,711, Dec. 18, 1928. Highly bleached montan wax is produced by treating montan wax with a larger amt. of oxidizing agents than is needed for completely bleaching the wax and converting at least part of the carboxyl groups of the free org. acids present in the product into compds. contg. the CO group, but not contg. a carboxyl H atom. Cf. C. A. 22, 2851.

Wax from lignite. MAURICE DEVAUX and HYDROCARBURES ET DÉRIVÉS. Fr. 641,203, Mar. 3, 1927. Wax is extd. from damp lignite with a volatile solvent b. below 100° and not miscible with water, such as C_6H_6 , and then with a binary org. solvent, b. below 100° , of which 1 component is miscible with water, e. g., a mixt. of equal parts of C_6H_6 and EtOH .

Coal tar. URBANA COKE CORP. Fr. 640,989, Sept. 15, 1927. Coal is distd. at a temp. of about $750\text{--}850^\circ$ to obtain a tar of sp. gr. 1.1 to 1.15 and contg. between 12 and 18% of tar acids. A suitable plant is described.

Recovery of tar. RENÉ L. A. GESSIEN and LOUIS GRANGER. Fr. 642,444, Oct. 15, 1927. In the distn. of substances yielding tar in closed containers, the tar is drawn off from the retorts without being distd.

Recovery of tar. PETER FRANKE. Fr. 642,586, Oct. 19, 1927. Waters from coke-oven plants and the like are freed from org. substances rich in tar by means of the fraction of tar oil boiling between 230° and 350° , from which PhOH and pyridine have been removed.

Coking. FRANS PUENING. U. S. 1,699,448, Jan. 15. An app. is specified comprising spaced parallel members such as iron walls which are preliminarily heated sufficiently to supply heat for subsequent coking, material to be coked is placed in the chambers between these heated members and the latter are moved closer together to compress the material while coking it by the heat thus supplied; evolved vapors are removed, and the coked material is removed by sepn. of the confining walls which retain it.

Coking. RICHARD FEIGE. Fr. 642,144, Oct. 10, 1927. Coking at low temps. is carried out in a vessel contg. rotating plates flat or funnel-shaped on to the center

of which the matter to be treated is directed in thin layers and is carried outwards by centrifugal force on to a stationary funnel, which directs it to the center of the next plate.

Coking. INTERNATIONAL COMBUSTION ENGINEERING CORPORATION. Ger. 469,168, Oct. 25, 1925. Coal dust in suspension is heated to between 260° and 480° to drive off the water before being submitted to the coking process. App. for carrying out the coking is described.

Coke oven. FIRMA CARL STILL. Ger. 469,124, July 10, 1927. Details of construction.

Regenerative coke oven. GUSTAV O. WOLTERS. Ger. 469,284, Mar. 15, 1925. Details of gas currents.

Coke-oven construction. CARL OTTO. U. S. 1,698,272, Jan. 8.

Coke-oven construction. WILLIAM M. PERSON. U. S. 1,698,651, Jan. 8.

Regenerative coking oven. HINSELMANN, KOKSOFFENBAU G. M. B. H. Ger. 469,480, Feb. 23, 1926.

Apparatus for operating coke-oven doors. CARL STILL. Fr. 642,239, Oct. 13, 1927.

Means for compressing coal in coking ovens. HEINRICH SALLEN. Ger. 468,682, Feb. 8, 1925. A removable wedge-shaped attachment to the oven door compresses the coal against the sides of the oven.

Coke briquets. SYNTHETIC AMMONIA & NITRATES, LTD., AND H. A. HUMPHREY. Brit. 291,543, March 11, 1927. Powdered fuel is preheated in an uncompressed state and on nearing the coking temp. is forced by pressure through a container where coking occurs and the coke takes the shape of the container, which may contain a grid for dividing up the coked mass. An app. is described.

Coking carbonaceous material such as coal or lignite. FRANZ PUENING. U. S. 1,698,347, Jan. 8. Coking receptacles which may have metal walls are moved progressively through a heating region of a described app., in which they are heated sufficiently to supply subsequently heat for coking, and are then charged with the material to be coked, and after coking is effected the contents of the receptacles are discharged and they are then reheated and the process is continued cyclically.

Plant for dry-cooling glowing coke. GEBRÜDER SULZER. A.-G. Swiss 127,684, Mar. 26, 1927. Addn. to Swiss 122,951. Details of construction.

22- -PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

F. M. ROGERS

Varied factors control choice of cracking process. ERNEST OWEN. *Chem. Met. Eng.* 35, 737-40(1928).—Factors affecting the choice of a cracking process are (1) yields of gasoline, (2) quality of products, (3) capital investment, (4) fuel consumption, (5) gas and coke production, (6) flexibility of operation, (7) safety of operation, (8) ease and simplicity of control, (9) service factor, (10) operating costs, (11) license charges and patent protection. The following processes are discussed briefly and illustrated with sketches, Cross, Holmes Manley and Tank and Tube. The characteristics of cracked gasoline are discussed briefly. A superior anti-knock motor fuel is now being obtained from cracked gasoline.

Cracking of gas oil from Boryslaw. ANTONI SZAYNA. *Przemysl Chem.* 11, 451-46(1927); cf. *C. A.* 23, 507.—A fraction of Boryslaw gas oil above 225° was submitted to cracking influences under various conditions of temp., pressure, catalysts, and contg. vessels. Conclusions drawn are strictly limited to the oil studied. The only effect of the contg. vessel, whether made of Cu, Fe or quartz, is that of heat cond. of the material. Of activated charcoal, reduced Ni, and AlCl₃ tried as catalysts only the last showed a positive effect on the yield of benzine, a 44.4% yield by wt. being obtained. As the temp. of the treatment rises the yield on one treatment rises to a max. of 27% sp. gr. of the product and residue increases, % of unsatd. hydrocarbons in the product diminishes slowly, % of the aromatic compds. increases, and of the satd. compds. diminishes. Pressure has no effect on yield within exptl. error, but the degree of satn. rises rapidly with increasing pressure. H₂ used under high pressure as in the Bergius method is undoubtedly absorbed, probably by satisfying the newly produced free valences.

The Edeleanu refining process in the large plant. BERNHARD NEUMANN. *Chem. Fabrik* 1928, 641-4.—A very complete description is given of the Edeleanu process of

treating petroleum distillate with liquid SO_2 with diagrams and photostats. Nothing new. D. F. BROWN

The variation of viscosity with temperature. III. C. WALTHER. *Erdöl u. Teer* 4, 614-6(1928).—It is shown that the rate of change of viscosity of different oils, with pressure, increases, at const. temp., with their viscosities, and, for the same viscosity, with their temp. factors. Hence, at const. bearing temp., the best lubricating oil is the one with the largest temp. factor. With fluctuating bearing temp., the oil with the lowest temp. factor is best adapted. F. S. GRANGER

Natural crude-oil emulsions from the region Boryslaw-Tustanowic. II. TADEUSZ KUCZYNSKI. *Swow Polytech. Przemysl Chem.* 11, 429-50(1927); cf. *C. A.* 23, 270.—Droplets of water or of aq. solns. suspended in pure oil are always positively charged, i. e., they obey the rule of Coehen. Droplets of water suspended in unrefined or crude oils are positively charged when they show an acid reaction, but negatively charged when they show an alk. reaction. This rule clears up in full the mechanism of action of alk. solns. on natural emulsions in the crude oils. Loam, sand and asphalt obtained from acid leavings are charged negatively. This explains the mechanism of filtering action of sand. A phenomenon analogous to rapid electrolysis was discovered, depending on the fact that cataphoresis proceeds the faster the more rapidly revolving are the electrodes used. The asphaltic substances are an emulsifying agent in emulsions, and it is because of this that oils can be refined by means of producing emulsions. Attempts to synthesize emulsions without the aid of emulsifying agents led to a new convenient method of obtaining emulsions by elec. dispersion without producing an arc. The dielec. consts. of various oils before and after refining with H_2SO_4 and by physical methods were investigated; they are always lower in the product than in the raw material. Through the study of the influence of the elec. field on some very easily polymerizing substances, e. g., turpentine, it was shown that the emulsion probably changes the chem. compn. of the crude oil, polymerizing some of its components. A. C. Z.

Refining mineral oils with decolorizing powder. STANISLAW GASIOROWSKI. *Przemysl Chem.* 11, 466-72(1927).—Distillate of spindle oil from Boryslaw-Tustanowic crude oil was studied under the influence of a decolorizing powder. After the treatment the oil was filtered and the color of the filtrate compared with a standard $\text{K}_2\text{Cr}_2\text{O}_7$ soln. The adsorption is practically complete within less than 1 min. This shows that laborious or protracted mixing is superfluous. The effect of temp. between 20° and 110° is practically insignificant but outside these limits adsorption falls off sharply. It is useless to employ more than a certain min. amt. of the powder as further addns. do not help. Repeated treatments with fractional parts of a given quantity of powder are not so effective as one treatment with the whole batch. A. C. ZACHLIN

Water-miscible mineral oil preparations. RALPH HART. *Ind. Eng. Chem.* 21, 50-56(1929).—The manuf. of clear water-miscible mineral oils is primarily a problem in miscibility; free oleic acid is essential to a uniform product. Miscibility curves for sodium oleate and Turkey-red oil as emulsifiers are given by means of which uniform and non uniform mixts. were traced. Free oleic acid decreases the stability of the emulsion and may even prevent it altogether. The kind and quantity of mineral oil have practically no effect on the quantity of oleic acid the mixt. will tolerate and still give a good emulsion. Alc. acts as a liquefier for the soap, at first decreases and then as more alc. is added increases the quantity of oleic acid required for a homogeneous product and exerts no direct effect on the emulsion. Addn. of alkali in the absence of alc. first decreases and then increases the amount of free oleic acid required for a homogeneous product. In the presence of alc. the more alkali the less oleic acid is required to clear. The more neutralized the Turkey-red oil the better it functions as an emulsifier. Tests for the raw materials and for the stability of sol. oils are given. D. F. BROWN

Grozny oil gases. P. I. BOGAYEVSKII. *Neftyanoe Khozyaistvo* 15, 636-8(1928). The quantity of gasoline absorbed by natural gas was detd. by the absorption method. 9.42 gal. of gasoline (sp. gr. 0.700) per 1000 cu. ft. of gas were obtained from Novo-Grozny gushers, 5 gal. (sp. gr. 0.640) from Staro-Grozny gushers and 1.687-3.928 gal. (sp. gr. 0.635-0.658) from Staro-Grozny wells, where exhaust pumps had to be used. This includes gasoline condensed in the pipe lines. A. A. BOEHLINGK

Thermal characteristics and heat balance of a large oil-gas generator. ROBERT D. PIKE AND GEORGE H. WEST. *Ind. Eng. Chem.* 21, 104-9(1929).—The results of a five-day test on a large city-gas generator of the Jones type at the San Francisco plant of the Pacific Gas and Electric Company are described. The operating cycle is 10 min. of "make," during which oil and steam are introduced at several points in each of the two connected shells, passing downward in each shell, and the gas is removed to

the wash box, where the temp. is slightly above atm., and lampblack and tar are removed; a "blow" of five min., intended to burn out the C deposited in the generator during the make. Here the oil and most of the steam is shut off and air is blown in the top of the primary shell and auxiliary air is introduced at the bottom of the secondary after the first min. of the blow. The "heat" lasts five min., during which oil and air are fed in at the top of the primary and burn while passing both shells, leaving at the top of the secondary. Detailed material and energy balances are included for the test. 83,500 B. t. u. is lost as sensible heat in waste gases per 1000 cu. ft. of gas made or 376×10^6 B. t. u. per 24 hrs. operation, the temp. of the waste gases being 790° . A waste-heat boiler at 50% efficiency could recover 188×10^6 B. t. u. per 24 hrs. An economic analysis of lampblack production shows that 18.5% of the output is lampblack and 3.28% is tar, both of which are utilized in the boiler plant for steam production. The efficiency of the gas-producing process can then be materially increased by elimination of the production of these two by-products. A patented modification of the Jones process which allows this elimination is described briefly. J. H. PERRY

The Conradson value. W. JUNOSZA PIOTROWSKI AND J. WINKLER. Chem. Lab. Refinery "Galicja," Drohobycz. *Przemysl Chem.* 12, 573-80(1928); cf. Conradson, C. A. 21, 2379.—A detn. of the Conradson value when performed strictly according to the standard procedure is sufficiently accurate (showing an error of 0.2%) and because of its simplicity should be made frequently in tests on lubricating oils. For well-refined oils it can be used to decide whether a given oil is a distillate or a residue, because in the former it never exceeds 1%, and in the latter it is as a rule over 1%, and may go as high as 7%. The addn. of fatty acids up to 10% does not affect the value. Practical tests give results proportional to the detd. Conradson values, i. e., the lower the Conradson value the less carbon is there left in the cylinders of the automobile engine. It can be noticed in results of tests on Polish oils that the distillate from a naphthenic crude oil as well as crude oil of aromatic character has the least inclination to carbonization, while oils from naphtheno-aliphatic crude oils have a greater tendency to coking. Oils obtained as low-pressure (3 mm. Hg.) distillates although unrefined have the lowest Conradson value. From all this it follows that a high content of unsatd. hydrocarbons which at a higher temp. easily decompose, leaving a carbon residue, probably influences the Conradson value. Method, procedure and exptl. data are presented. A. C. Z

Sediments in turbine oils. N. I. CHERNOZHUKOV. *Izvestiya Teploekhnicheskogo Instituta* (Russia) (*Trans. of the Thermo-Tech. Inst.*) 1927, No. 4, 41-4.—Reviewing the literature, C. disagrees with the statement of Funk (cf. C. A. 18, 3711) that cases are known where oil with a comparatively high % of acids (org.) was used for a considerable time without any noticeable harm. According to C., the higher viscosity of such an oil is likely to cause trouble owing to insufficient circulation and lubrication. To investigate the sludge a sample was taken of oil used in one of the turbines for 4 months. The sludge was composed of water (Dean and Stark) 35.5%, oil 29.5% and 35.0% of compds. insol. in gasoline; these latter were composed of 16.5% alc.-sol., 72.6% C_6H_6 -sol. and 11.2% C_6H_6 -insol. compds. The alc. soln. comprised org. acids and org. Fe salts. The benzene soln. contained Fe and Cu salts from org. acids and asphalts. The C_6H_6 -insol. part was composed of free Fe (detd. as Fe_2O_3) 13.92%, and free Cu (detd. as CuO) 5.06%, the rest being sand, C, etc. The ash contained Fe_2O_3 66.6%, CuO 5.1%, sand, etc., 28.0%. This turbine oil had the following characteristics before use: d_{15} , 0.8825, flash pt. (Brenken) 198° , viscosity E 50° , 3.98, ash 0.001%, acidity 0.006% SO_3 , sapon. none, water by Dean and Stark none. The corresponding figures for used oil were: d_{15} 0.8961, 192° , 5.35, 0.007%, 0.11% SO_3 , 5.1%, 0.4%. The same turbine was washed out and charged with new oil which formed emulsions and showed characteristics of an inferior oil; this is explained by the presence in the turbine of a part of the sludge from the old oil evidently not properly removed. C. distinguishes 3 different kinds of sludge: (1) Sludge formed through the polymerization and oxidation of tarry substances and having the appearance of the so-called asphaltenes. This sludge is never formed in properly refined oils. (2) Sludge of a distinctly acid character formed through the oxidation and polymerization of unsaturated compds. and the basic hydrocarbons of the oil. The sludge is usually a sticky and viscous mass of a brownish color. (3) Sludge comprised of Fe and Cu salts from org. acids; they are formed through the presence of water in the turbine, whereby $Fe(OH)_3$, etc., are formed, which react with org. acids and forms org. salts. Iron soaps are good emulsifying agents and the excess ppts. on the walls of the turbine forming very adherent crusts, this applies also to Cu and other soaps. The soap increases the viscosity of oil decreasing its lubricating value, the thermometers become covered interfering with temperature readings, etc. A. A. POERTLING

Methods of analysis of light gasolines. J. GIRZEJOWSKI. Chem. Lab. "Gazolina," Boryslaw. *Przemysl Chem.* 12, 584-6(1928).—Gases from the Engler condenser are led to a long glass tube from which there are branching several outlets to as many adsorption towers contg. activated charcoal. By manipulating the proper stopcocks, gases from the various fractions are led to desired towers where they are completely adsorbed, and with which they are later weighed. In some of the expts. reported as much as 68% of the gasoline was recovered as adsorbed gases. The resulting error of the distn. analysis falls from 40% to 1 or 0.5%. A. C. ZACHLIN

Action of nitric acid on Polish gasoline. EUGENIUSZ TURKIEWICZ. Jan Kazimir Univ., Lwow. *Przemysl Chem.* 11, 381-9(1927).—This investigation was concerned with the action of HNO_3 in presence of H_2SO_4 on the lightest fractions of Boryslaw gasoline prep'd. by the compression method. The presence of benzene and toluene in this gasoline was established. They probably undergo quant. nitration. Trinitrohexane obtained by Zaloziecki (Akad. Umiejetnosci, Krakow. 1903) could not be identified, perhaps because of decompn. caused by many crystns. A. C. ZACHLIN

Anti-knock fuels. GRAHAM EDGAR. *J. Soc. Chem. Ind.* 47, 230-2T(1928); cf. C. A. 23, 270.—General explanation in simple terms. ALBERT L. HENNE

Metallic colloids and knock suppression. H. L. OLIN AND W. J. JEBENS. *Ind. Eng. Chem.* 21, 43(1929).—A repetition of the work reported in an earlier paper (C. A. 21, 817) on the effect of metallic colloids dispersed in gasoline showed, as before, that they played no part in knock suppression. It was found also that Sims and Mardles (C. A. 20, 2750, 2806) who reached entirely opposite conclusions in work done at approx. the same time were in error, because of faulty technic in prepg. their materials. H. L. O.

X-ray quantitative analysis of tetraethyl lead in gasoline. R. H. ABORN AND R. H. BROWN. *Ind. Eng. Chem. Anal. Ed.* 1, 26-7(1929).—A quick method requiring standardization and with an error in analysis of 0.1 cc. of PbEt_4 is described. M. D.

Greases to withstand high vacua. FR. HEINRICH AND F. PETZOLD. *Chem. Fabrik* 1928, 692-3.—Nine samples of greases for stopcocks were tested by use of stopcocks connected to small vessels provided with vacuum gages. Commercial greases show wide variations in properties, and "home-made" stopcock greases are quite as good as those on the market. Greases contg. vaseline, pale crepe and paraffin are recommended, but very careful work is necessary in prepg. them. W. C. EBAUGH

Paraffin wax in Apsheron crude oils. A. N. SAKHANOV AND L. G. ZHERDEVA. *Vysvanye Khozyaistvo* 15, 639-42(1928).—To det. paraffin wax in mineral oils mix 10 g. of crude oil with 500 cc. of light gasoline and treat at room temp. with 60-70 g. of fuller's earth; ext. the fuller's earth with gasoline in a Soxhlet extractor for 2 days, to dissolve the paraffin wax; evap. the ext. so obtained to 10-20 cc. and ppt. the wax by Holde's method with alc.-ether; redissolve the crystals in ether and reppt. by the Holde method to sep. the last traces of oil. By this new method 2-3 times more paraffin wax, m. 65° , was detected in the Surakhanui crude oil. Surakhanui paraffins have a ceresin character; the low-melting fractions are plastic. Balakhanui-Sabunchi crude oil yielded 1.95% of wax, m. 50.5° ; the sepd. wax recrystd. from ether was similar to the Surakhanui wax except in m. p. (37.5°). Bibi-Eibat crude oil contains 1.25% wax, m. 50° , which is also of the ceresin type. Binagadui crude oil has 0.7-0.8%, m. 47° , and Kutmaki crude oil only traces amounting to 0.1-0.2%. The paraffin contained in Apsheron crude oils is distributed in the higher fractions and particularly in the heavy bottoms as compared with the Grozny crude oils, where paraffin distills over with the medium fractions. The Surakhanui paraffin was further dissolved in Baku solar oil and the satn. temps. were detd. 100 g. of this oil dissolved 0.18% of wax at 19° ; the soly. was 10.42% at 65° for a wax m. 83° . The soly., then, of Surakhanui wax is the higher the lower its sp. gr. and the lower the m. p. of the ceresin. Surakhanui waxes crystallize in the form of many single crystals, which drop to the bottom of the container and hardly form a compact mass; the Grozny waxes soon become gelatinized. A Surakhanui crude oil congeals at -20° having 6% wax as compared with Grozny crude oil with a smaller amount of paraffin, which congeals at 10° . The Grozny crude oils having a high proportion of wax in the lubricating oil fractions are noted for their viscous lubricating oils at low temp., while the Baku oils, which have a high % of wax in the heavy bottoms, give lubricating oils with lower freezing points. A. A. B.

Resin determination in mineral oil products. N. I. CHERNOZHUKOV. *Izvestiya Tekhnicheskogo Instituta (Trans. Thermo-Techn. Inst. (Russia))* 1927, No. 4, 35-6.—A 15 cc. centrifugation flask graduated in 0.1 cc. is charged with 5 cc. H_2SO_4 (d. 1.84) and an equal vol. of the oil to be tested is added from a buret (viscous oils must be dild. in equal parts with gasoline with initial b. p. above 100° which has been previously

treated with an equal vol. of $H_2SO_4.H_2O$ to ext. olefins and aromatics). The temp. is noted and the flask shaken for at least 5 mins., and centrifuged for 5 mins. Naphthenic acid (1-2 drops) is added if the sludge does not ppt., the flask is then shaken again and centrifuged for another 5 mins. or longer until the sludge level becomes const. The quantity of naphthenic acids used must be added to the final readings, which are made after the soln. has cooled to the original temp. The readings are accurate within 0.05 cc. The reading so obtained less the vol. of acid divided by the vol. of the oil and multiplied by 100 gives the % of sludge (resin) by vol. in the mineral oil product. A. A. B.

Petroleum asphalts and resins. N. I. CHERNOZHUKOV. *Neftyanoye Khozyaistvo* 15, 670-3(1928).—Paraffinum liquidum of viscosity E_{60} 5.0, oxidized by Butkov's method at 150° under 15 atm. O_2 for 4 hrs., yields, on diln. with petroleum ether, 9.25% of a white ppt., contg. C 71.64, H 8.81, O 19.55%; S is absent; acid no. 75; the acidity of oxidized oil 36 mg. of KOH. The same oil heated with O_2 at 250° and 12 atm. for 2 hrs. had dark yellow tint; a flaky sediment was again obtained on adding petroleum ether. Neither asphaltenes nor carbenes were formed. Crude oils from Balakhanui, Grozny (non-paraffinic) and Emba with O_2 or air for 3 to 12 hrs., at $150-200^\circ$ and 15 atm. gave sediments of an asphaltenic character; simultaneously the oils become brighter. The asphaltenes sepd. from turbine oil distillate had the formula $C_{172}H_{176}O_{14}S$; from light spindle oil $C_{136}H_{142}O_{12}S$. Baku and Emba white oils of viscosity E_{60} 5 heated with 3% of S for 3-4 hrs. at $200-270^\circ$, the S-contg. oils oxidized under pressure, and dild. with petroleum ether gave a dark-colored ppt. This ppt., filtered, washed with petr. ether, dissolved in benzene and reprecipitated with petr. ether 5 to 6 times gave finally a ppt. amounting to 0.2 to 0.4% of the original oil, sol. in C_6H_6 , CS_2 and $CHCl_3$, insol. in petr. ether. On heating to 100° in the presence of air it became insol., melted at higher temp., with decompn. and swelling; i. e., asphalt-like compds., $(C_{24}H_{27}O_3S)_x$, were obtained from medicinal oil and $(C_{36}H_{41}O_6S)_x$ from white "viskozin." Tuichinin after pptg. the asphaltenes from crude oil with petr. ether treated this oil with dry HCl and obtained a considerable amount of a compd. after another petr.-ether treatment which was very much like asphaltenes. When treating the sulfur-treated oil with HCl asphaltenes were also obtained. On treating the S-treated oils with H_2SO_4 , SO_2 is developed proving that an oxidation process is taking place; the acid sludge looks like ordinary acid sludge and the oil so obtained has a yellow tint. The compds. obtained as a result of S treatment and oxidation are adsorbed by fuller's earth. These tars obtained from Baku medicinal oil after the sepn. of asphaltenes amounting to 5.3% had the compn. C 80.69, H 11.26, O 7.05, and S 1.00%. They are very similar to tars obtained by Sakhanov from machine-oil distillate from Grozny non-paraffinic crude oil. Conclusion: Asphaltenes are formed from crude oil by unknown S compds. All S compds. contained in oils and able to change into asphaltenes are in the following state: (1) Purely sulfurous compds., (2) S compds. in different stages of oxidation, sol. in oil products and pptg. on diln. of the crude oil with petr. ether, (3) sulfurous compds. with a higher degree of oxidation, pptg. with petr. ether and sol. in benzene (asphaltenes), (4) sulfurous compds. highly oxidized insol. in benzene, CS_2 , etc. (carbenes). A. A. BOEHLING.

Asphalt-precipitating benzene from mineral oils. II. H. BURSTIN AND J. WINKLER. Chem. Lab. Refinery "Galicia," Drohobycz. *Przemysl Chem.* 12, 581-3(1928). To establish further the recommendations made earlier (cf. C. A. 22, 4786) B. and W. report the results of comparative tests on the asphaltene-pptg. power of 3 benzenes, one of Kahlbaum, and two others made by mixing Boryslaw gasoline with Boryslaw benzene and cracked gasoline, both of which conformed to the specifications of Holde; all three gave different results. In order to establish a uniform detn. of asphalts in oils purely aliphatic benzenes conforming to the specifications earlier devised should be used.

A. C. ZACHLIN

Simplification of oil-testing processes (FRIEDEBACH) 27. A system of analysis for oil-field waters (REISTLE, LANE) 14. Pure C (Fr. pat. 641,908) 18. Heat treatment of coal, mineral oils, etc. (Fr. pat. 641,344) 21. Separating paraffin constituents from fluid hydrocarbons (U. S. pat. 1,699,286) 10. Purifying liquids such as oil mixts. which tend to emulsify (U. S. pat. 1,698,270) 13. Heat exchange and pumping apparatus for heating and pumping oils (U. S. pat. 1,697,605) 1. Apparatus for separating oil and water by gravity (U. S. pats. 1,698,002; 1,698,067 and Brit. pat. 291,123) 1. $PbEt_4$ (Fr. pat. 642,120) 10. Me formate or similar formates as solvents in purifying oils (Brit. pat. 291,817) 13. Air-excluding device for C_6H_6 petroleum, etc. (Ger. pat. 469,293) 1.

EHLERS, CURT: *Schmiermittel und ihre richtige Verwendung.* Leipzig: Otto

Spamer. 112 pp. Paper covers, M. 8; bound, M. 10. Reviewed in *Ind. Eng. Chem.* 21, 95(1929).

Distillation of petroleum. ALLGEMEINE GES. FÜR CHEMISCHE INDUSTRIE M. B. H. (Lazar Edeleanu, inventor). Ger. 469,289, June 26, 1927. To reduce the S content and improve the odor of petroleum hydrocarbons, the distillate is treated with liquefied SO_2 and the part insol. therein sepd. and treated with a dil. alk. soln. of PbO , with or without addn. of S. A table of distillates and their properties is given.

Distilling petroleum oil. WARREN K. LEWIS and NATHANIEL E. LOOMIS (to Standard Oil Development Co.). U. S. 1,697,195, Jan. 1. A body of oil is distd. by direct fire heat under very low abs. vapor pressure and at a temp. below that at which substantial cracking would occur in the body of oil; vapors are led off through substantially unobstructed passages for condensation and no substantial drop in temp. is permitted in the vapors until they approach the condensing zone, so that refluxing is "minimized." An app. is described. Cf. *C. A.* 23, 967.

Still (with scrapers moving over its bottom) for distilling petroleum oils. HENRY S. BETTINGILL, JR. (to Empire Refineries). U. S. 1,698,507, Jan. 8.

Catalytic oxidation of petroleum hydrocarbons. CARLETON ELLIS (to Ellis-Foster Co.). U. S. 1,697,262, Jan. 1. A reaction mixt. of petroleum vapor and air is passed over a catalytic mass which may comprise Cu gauze or Al and V oxide and which is maintained at a "black heat" just below a temp. of redness by suitable cooling. The process is applicable to the production of aldehydes and acids from oil gas, etc. U. S. 1,697,263 specifies effecting similar processes with kerosene or other petroleum hydrocarbons with use of a catalytic mass such as Fe and V or their oxides which possesses high heat conductivity. U. S. 1,697,264 specifies production of org. acids or other oxidation products by cracking oil such as kerosene under a pressure of 4 or 5 atm., removing the heavier products of the cracking, and passing the residue of the cracked products admixed with air through a mass of catalytic material which may comprise Mo or V oxides supported on a granular carrier, at oxidation temp., passing the oxidation products through water, oil and silica gel, resp., and recovering gasoline, org. acids and other products of oxidation from the scrubbing agents. U. S. 1,697,265 specifies subjecting vapors derived from petroleum cracking to the action of O in the presence of a catalyst which may comprise V oxide on pumice and which is maintained at a temp. of incipient redness so that oxidation products such as aldehydes and acids are obtained. U. S. 1,697,266 specifies oxidation of petroleum oils such as kerosene by treatment with an or other O-contg. gas at a temp. below redness under conditions which will produce oxidized products such as alcs., ketones, aldehydes, acids, etc. while controlling the quantity of O used to regulate the extent of oxidation effected. U. S. 1,697,267 specifies passing gas from petroleum cracking into contact with a heated catalyzer which may comprise Cu gauze or Fe, Cr, V or Ag compds. and which is maintained at a temp. of just below dull redness, in the presence of an O-contg. gas such as air while using more than 1 atom of O for each mol. of readily oxidizable constituents in the gas to produce products such as aliphatic acids, etc.

Petroleum spirit. WILLIAM-MAY KNOWLING (Michael Kostevitch, inventor). Fr. 641,926, Mar. 16, 1927. Petroleum spirit, particularly for motors, is purified by means of active C either alone or with SiO_2 gel.

Hydrocarbons from rock and sand. BRUCE M. CLOUD. U. S. 1,697,260, Jan. 1. Natural hydrocarbon-contg. rock and sand such as that of depleted wells is treated with water gas or other gas comprising CO and H, together with C_2H_2 , in order to effect further oil recovery.

Purifying hydrocarbons. ALLGEMEINE GESELLSCHAFT FÜR CHEM. INDUSTRIE M. B. H. Fr. 641,312, Sept. 22, 1927. The products of distn. of natural hydrocarbons have their quantity of S reduced and their disagreeable odor removed by a treatment with an alk. soln. of Pb oxide after the usual Edeleanu treatment with liquid SO_2 .

Purification of hydrocarbon compounds. ERNST B. AUERBACH. Can. 285,782, Dec. 25, 1928. Oils contg. constituents of different mol. wt. are purified by bringing the oils into contact with liquid CO_2 , absorbing constituents of lighter mol. wt. in the liquid CO_2 , sepg. the liquid CO_2 and absorbed constituents from the remaining oil and then sepg. the absorbed constituents from the CO_2 .

Treating hydrocarbon oils. CHAUNCEY B. FORWARD. U. S. 1,698,811, Jan. 15. A stream of oil such as crude oil is passed through heating coils exposed to superheated steam and the heated product is atomized together with a compressible fluid such as superheated steam in a closed vessel; the volatilized and atomized product is forced from the closed vessel through heating coils exposed to superheated steam of about

540° or higher until highly heated and volatilized material is finally liquefied and the liquids thus obtained are sepd. An app. is described.

Distilling hydrocarbon oils under pressure. FRANCIS M. ROGERS and EDWARD J. SHAEFFER (to Standard Oil Co. of Ind.). U. S. 1,697,573, Jan. 1. In order to produce products of low b. p., an oil such as an oil of 30° Bé. is heated under pressure to a conversion temp., and liquid hydrocarbon oil is introduced into the vapors evolved by the oil, the liquid hydrocarbon having approx. the characteristics of the desired products, vapors of the desired products are removed together with vapors of the oil introduced and condensed products of higher b. p. than those desired are returned to the oil undergoing heating for further treatment. An app. is described. Cf. C. A. 22, 3289.

Refining hydrocarbon oil distillates. HENRY J. BRODERSON (to Standard Oil Co. of Ind.). U. S. 1,698,428, Jan. 8. A flowing stream of distillate such as naphtha, pressure still distillate or "burning oil" is heated to about 32-37° and there is continuously added to the oil stream a treating reagent such as Na plumbite soln. and the oil stream and admixed reagent are then conducted into a body of the liquid treating reagent below the surface of the latter so that the oil passes through the reagent and is continuously withdrawn as it seps. above the main body of reagent. An app. is described.

Partial oxidation of cracked hydrocarbon products. CHARLES S. PALMER. U. S. 1,699,627, Jan. 22. Oil or gas is cracked to obtain products more active and capable of oxidation and these products are then partially oxidized to form aldehydes and other products by the further action of oxidizing gas such as O or air and steam which is preheated by heating from the cracking operation. An arrangement of app. is described.

Desulfurizing liquid hydrocarbons. T. B. KIMBALL. Brit. 291,379, May 31, 1927. S compds. such as mercaptans are removed from hydrocarbon distillates such as gasoline or kerosene by bringing the hydrocarbons in vapor form into contact with an alk. soln (suitably an aq. NaOH soln.) heated to above the condensation temp. of the vapors but below the b. p. of the soln. used. The treatment may be effected counter-currentwise in a scrubbing tower.

Cracking oils. G. C. HARGROVE (to Gasoline Products Co.). Brit. 290,996, May 23, 1927. Conditions of temp., pressure and time of a cracking operation are so controlled that not more than 25% of the crude oil is converted into gasoline in a single passage through the app. The process may be carried out continuously and the fresh feed of crude oil may be dild. with about twice its volume of clean overhead distillate produced. The crude oil is preferably subjected to a preliminary "stripping" to recover gasoline which it naturally contains. An app. is described.

Cracking of oils. LOUIS J. WALSH. Can. 285,669, Dec. 18, 1928. Liquid hydrocarbons for cracking are preheated and forced in a stream under initial pressures of 40 or more atms. in succession through several tubular heaters having hydraulic resistance to flow, whereby flow is under successively diminishing pressures in each of said heaters. The material is heated in each of said heaters to a temp. appropriate to cracking in liquid phase at the pressure in the heater and acted upon during flow from heater to heater to volatilize and remove from the liquid stream substantially all of the volatile substance produced during flow in the preceding heater. The liquid material effluent from the heaters is subjected to vaporization at a temp. of 650°F. and a pressure of 4 atms. or less, and a portion of higher-boiling fractions of the product are recycled with the addn. of fresh feed stock.

Coatings for oil-cracking retorts. A. C. HOLZAPFEL. Brit. 291,585, April 30, 1927. The interior surfaces of oil-cracking retorts are coated with a paint-like compn. comprising water-glass, water, an alk. earth compd. such as slaked lime or magnesite and one or more powdered inert refractory mineral substances such as Ti oxide and fireclay and the coating is heated to an oil-cracking temp. Several coatings may be applied, as may also a temporary waterproofing coating of heavy mineral oil.

Purifying mineral oils. G. PETROV. Brit. 291,823, Feb. 1, 1927. Mineral oils and naphtha are treated in the presence of fatty acids such as stearic and oleic acids with a sulfonating agent. Tarry matter seps. and is heated with water to remove the sulfonic acids and the treated oil may be washed with alkali.

Refining mineral oils. ERIC T. HESSLE. U. S. 1,696,913, Jan. 1. Oils such as crude petroleum or shale or tar oils or gas oils while heated (suitably to about 250-400°) and in the form of a "true fog" (which may be produced by a special described app.) are subjected to a "decompn. catalyst" contg. Sn together with about 1% of Sb. An app. is described. A high yield of gasoline may be obtained.

Oils, etc., for use as electric insulating materials. FELTEN & GUILLEAUME CARLS-

WERK A.-G. Brit. 291,722, June 3, 1927. Insulating oils, mixts. of oils and resins, transformers, switch-gear casings, storage containers for cable-impregnating substances, etc. are stored in an inert gas such as N.

Electrical insulation. I. G. FARBENIND. A. G. (Erik Reissmann and Adolf Richter, inventors). Ger. 488,394, Dec. 5, 1924. The non-resinifiable parts of natural mineral oils sol. in liquid SO₂ are used as insulating materials for high-tension switches, transformers, etc.

Cleaning crude oil. WILLIAM L. PALMER. U. S. 1,699,374, Jan. 15. Oil such as crude petroleum is treated with a reagent mixt. prepd. by dissolving oxalic acid in a solvent such as glycerol, honey or castor oil and admixing this soln. with glacial HOAc, cresylic acid and oleic acid, and the oil and reagent are permitted to stand until water settles out from the mixt.

Refining crude fuel oil. ELMER A. SPERRY (to Sperry Development Co.). U. S. 1,699,379, Jan. 15. The oil is centrifuged under pressure and simultaneously heated, in order to prepare it for use in Diesel engines. An app. is described.

Handling distillation residues of asphaltic crude oils. OSCAR E. BRANSKY and FRANCIS M. ROGERS (to Standard Oil Co. of Ind.). U. S. 1,698,471, Jan. 8. The residue is dild. with a hydrocarbon oil having a b. p. within the gasoline range, and undissolved asphaltenes are sepd.

Oil from shales, coal or similar oil-bearing materials. N. H. FREEMAN. Brit. 291,475, Dec. 1, 1926. The material is heated to and maintained at a predetd. crit. temp. until substantially all the hydrocarbon content is sol. in a hydrocarbon oil, as described in Brit. 248,014 (C. A. 21, 647), and the oil is removed in a heated entraining agent such as superheated steam, gas or oil vapor. Heating to about 300° for about 1 hr. is ordinarily suitable. An app. and various details are described.

Automatic crude-oil discharge valve. K. M. MOSHKOVSKII. Russ. 3916, Oct. 31, 1927.

Distillation of tar or oils. INTERNATIONAL COMBUSTION ENGINEERING CORP. Fr. 641,473, Sept. 20, 1927. A hollow heating body, the cross section of which is star shaped, is mounted inside the still and heated by hot gas.

Forged tubes suitable for oil pressure distillation apparatus. WALTER M. CROSS (to Gasoline Products Co.). U. S. 1,699,688, Jan. 22. In forming tubes for withstanding high temps. and pressures, an ingot of steel is annealed and drilled longitudinally rotated and forged on a mandrel to a definite length so as to leave end portions of greater wall thickness than the main portion of the tube, and the ends are forged on a mandrel of smaller diam. to produce constricted openings and bottle-neck-shaped ends.

Oil filter. WILLIAM H. McMACHEN and MARION F. McMACHEN. U. S. 1,698,600, Jan. 8. A filter is described which is suitable for purifying oil from internal-combustion engine crankcases.

Preservation of heated oils. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 641,147, Sept. 20, 1927. Deposition of solids or mud in oils heated for a long time as in transformers is prevented by the addn. of fuller's earth.

Detecting moisture in transformer oil. GOVERNMENT ELECTROTECHNICAL TRUST. Russ. 4712, Feb. 29, 1928. A strip of paper, asbestos, etc. is placed between 2 electrodes connected to an outside source of elec. supply. This app. is immersed in transformer oil which if wet displaces the oil in the paper, etc. by water and an elec. current begins to flow which is indicated on an electrometer.

Apparatus for separating oil from water. J. CRICHTON and J. CRICHTON & Co., Ltd. Brit. 291,123, Dec. 21, 1926.

Apparatus for separating oil and water or other liquids of different densities by gravity. FRANK PINK. U. S. 1,698,067, Jan. 8.

Apparatus for separating oil and water or other liquids of different densities by gravity. FRANK PINK. U. S. 1,698,002, Jan. 8.

Apparatus for separating benzene and water or other liquids by gravity. W. LINNMANN. Brit. 291,608, June 9, 1927.

Apparatus and system of operation for producing oil-gas. ALVIN J. BASSETT (to Bruce Macbeth Engine Co.). U. S. 1,698,525-6, Jan. 8.

Coking oils. STANDARD OIL CO. Fr. 641,168, Sept. 20, 1927. Hydrocarbon oils are coked at a temp. above 482° in vessels made of an Ni-Fe or Ni-Cr alloy, such as Monel metal to which the coke when formed does not adhere. A suitable app. is described.

Oil burner. M. I. L'VOVICH-KOSTRITZ. Russ. 4606, Feb. 29, 1928.

Oil burner. N. V. OSTRIKOV. Russ. 3888, Oct. 31, 1927.

Oil burner from steam boilers. V. A. VARGANOV. Russ. 3735, Oct. 31, 1927.

Fire-fighting equipment for oil wells. S. A. MNATZAKANYANTZ and K. K. RIDEL. Russ. 4601, Feb. 29, 1928.

Equipment for emptying mazout separated from water from oil tankers. N. F. SKVORTZOV. Russ. 3753, Oct., 1927.

Lead tetraethyl. CHARLES A. KRAUS and CONRAL C. CALLIS (to Standard Oil Development Co.). U. S. 1,697,245, Jan. 1. Pb is alloyed with about 10% of Na, the alloy is subdivided, suitably in N, while avoiding oxidation and is then reacted on with EtCl at a temp. of 35-70°. Cf. C. A. 23, 970.

Lubricant. JAMES W. FINLAY (to Pierce Petroleum Corp.). U. S. 1,699,961, Jan. 22. A "grease lubricant" contains mineral oil 73.5%, heavy tar 5% and small quantities of Ca and Na soaps of animal fats.

Lubricant. JOSEPH H. JAMES (to Clarence P. Byrnes, trustee). U. S. 1,700,055, Jan. 22. A lubricant suitable for various uses comprises partial oxidation products of mineral oil in the range from alcs. to oxygenated org. acids. U. S. 1,700,056 specifies greases contg. soap of mineral oil oxygenated org. acids.

Lubricating oil. GEORGE H. TABER, JR. (to Sinclair Refining Co.). U. S. 1,698,076, Jan. 8. Steam is injected into a body of oil contg. lubricating oil constituents and the latter are vaporized and the lubricating oil vapors are sep'd. from heavier constituents of the oil vapors produced and are treated with a caustic alkali soln. and condensed. An app. is described.

Filter for lubricating oil as used in internal combustion engines. ERNEST J. SWEETLAND. U. S. 1,699,680, Jan. 22. Structural features.

Treating used lubricating oil. EDWIN S. PEARCE. U. S. 1,698,273, Jan. 8. In order to clean oil such as that which has been used for lubricating railway car journals, the oil is introduced continuously into a tank and caused to flow upwardly in the tank, heated at the lower portion of the tank, and impurities are sep'd. at different points in the tank as the oil flows through it and may be retained by raffle bars on baffle plates. An app. is described.

Reclaiming used lubricating oil. GEORGE L. CHERRY (to DeLaval Separator Co.) U. S. 1,698,257, Jan. 8. Used oil contaminated with water and solids is heated to not above about 99° and mixed with NaOH in a substantially dry state until the NaOH is dissolved, and the oil is then sep'd. from impurities (suitably by centrifuging). An app. is described. Cf. C. A. 23, 698.

Apparatus for the dry distillation of schists. PATENTAKTIEBOLAGET GRÖNDAL-RAMÉN. Fr. 641,798, Oct. 4, 1927.

Treatment of bituminous schists. PATENTAKTIEBOLAGET GRÖNDAL-RAMÉN. Fr. 641,669, Sep. 30, 1927. Schists are prepd. for dry distn. by fine grinding and making into small balls by mixing with water and passing through a rotating drum.

Destructive distillation of bituminous materials. DEUTSCHE ERDÖL A.-G. Ger. 469,366, Feb. 21, 1926. The materials descend a shaft in sep. streams while a current of O-free heating gases ascends the center of the shaft out of contact with the materials. The distn. gases are withdrawn from the annular circumferential space in the shaft, the pressure in the gas-withdrawing space being always the same as that in the hot gas space.

Aqueous pastes from bituminous materials. LOUIS C. JONES, CHAUNCEY C. LOOMIS and HENRY W. BANKS, 3RD. U. S. 1,699,536, Jan. 22. Bituminous materials such as crude Trinidad asphalt are ground with water to produce a pasty mass, and then, without heating, gasoline or other suitable solvent for bitumens is added, while the grinding is continued to produce a smooth paste, and a small quantity of alk. material such as soap is also added to facilitate dispersion and form a product which is suitable for paints or other coating compds. U. S. 1,699,537 specifies forming a viscous mixt. of china clay and denatured alc., pouring into this mixt. while stirring a previously melted soln. of blown asphalt and resin, to effect dispersion, and adding alc. to maintain the viscous condition of the mixt. during the stirring and form products which may be used as an elec. insulation.

Aqueous emulsions of oils, tars, asphalt, sulfur, rubber, etc. NAAMLÖÖZE VENNOOTSCHAP DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ and H. LIMBURG. Brit. 291,393, June 1, 1927. Aq. emulsions or dispersions are prepd. by use of aromatic or hydroaromatic sulfonic acids of mol. wt. not less than 250 or their alkali, Ca or Mg salts. Sulfonic acids derived from treatment of mineral oil, contg. aromatic substances, with "oleum" may be used. Emulsions of asphalt or other materials thus prepd. are stated to be stable even in the presence of HCl, lime or concd. salt solns. and to be unaffected by boiling or freezing. Albumin in weakly acid soln., basic dyes, solns. of salts of multi-

valent metals or hydrosols having positively charged particles may be added to the prep'd. emulsions or dispersions. The sulfonic compds. may be added as stabilizers to rubber latex or similar compns.

Emulsions. BENNETT, INC. Brit. 291,502, Feb. 28, 1927. Aq. emulsions of bitumens, gums, waxes, etc., are prep'd. by feeding the molten substances continuously into an inclined cylinder wherein they are agitated by rotating helical blades while adding a continuous stream of emulsifying agent such as Na silicate soln. Various details of app. and manipulation are described.

Emulsion. ASPHALT COLD MIX (1925), LTD. Ger. 470,306, May 5, 1923. An aq. bituminous emulsion is prep'd. by mixing fatty acids with molten bituminous material with addn. of caustic alkali or alkali carbonate. The amt. of fatty acid is less than 5% of the wt. of the bitumen. The mixt. may contain 4% oleic acid, 0.5% of 1-2% NaOH and 25-50 parts of water to 100 parts of bitumen.

Artificial asphalt. ALBERT TUREK. Austrian 110,401, Mar. 15, 1928. Tars, tar mixts. and pitches which are unsuitable for the manuf. of artificial asphalt by treatment with air or O are rendered suitable for that purpose by mixing them with other tars so that their phenol content reaches 12-24%. Mixts. so prep'd. may be treated with warm air in presence of catalysts such as Fe_2O_3 contg. S.

Treating asphaltic residues of oil distillation. FRANCIS M. ROGERS (to Standard Oil Co. of Ind.). U. S. 1,698,452, Jan. 8. Residues obtained by distn. of asphalt-bearing crude oils are mixed with a hydrocarbon oil of lower viscosity such as "miner's oil distillate" and the mixt. is treated with H_2SO_4 and the added oil is thereafter sepd. from the residue (suitably by distn.) and the sepd. residue may be mixed with naphtha and treated with fuller's earth.

Apparatus for determining the crushing point of asphalt and bituminous products. HELFRIED FERMITZ. Ger. 470,119, Feb. 22, 1927.

Treating carbonaceous material such as asphalt or oil shale. DANIEL PYZEL (to Simplex Refining Co.). U. S. 1,699,989, Jan. 22. Bituminous material such as asphalt is initially mixed in a closed vertical retort with pieces of fire brick or other suitable inert non-combustible material in the form of pieces which will withstand high temps. without disintegration, and steam is injected into the lower part of the resulting porous mass to generate water gas; air is injected into the mass above the point of steam injection to establish a partial combustion zone, and gases of combustion are allowed to rise to the top of the porous mass to distil volatile matter from the carbonaceous material. An app. is described.

Acetic acid from wood carbonization. HERMANN SUIDA. U. S. 1,697,738, Jan. 1. A "detarred" mixt. of wood gases, pyrolygneous acid vapors and wood-spirit vapors, in vaporious or gaseous condition, is subjected to direct extn. with an extn. agent such as cresol which is difficultly sol. in water and has a b. p. higher than that of HOAc, to remove the HOAc from the mixt. and the HOAc is withdrawn in coned. form as a liquid with the extn. agent.

Dismountable plant for carbonizing and distilling wood. JEAN BONELLO. Fr. 641,893, Mar. 12, 1927.

Charcoal kiln. M. A. TOKARSKII. Russ. 4158, Aug. 31, 1928. The kiln is characterized by channels or free space between the brick work and the jacket provided for the escape of gases or vapors

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

What the x-ray tells us of the structure of cellulose. E. A. HAUSER. *Ind. Eng. Chem.* 21, 124-5(1929).—A review. R. J. H.

The structure of the crystallized components of cellulose. KURT H. MAYER AND H. MARK. *Ber.* 61B, 593-614(1928).—X-ray studies of cellulose show a cryst. component to be present, having a unit cell 10.3 A. U. long in the fiber axis direction and 7.9 and 8.7 A. U. long in the other directions. The unit cell contains 4 glucose residues. The following model is discussed in the light of the x-ray results and chem. considerations. Five C atoms and 1 O atom form a hexose ring with a 1:5 linkage. Two hexose rings are joined to form cellobiose by linkage through an O atom, the latter joining N C of one ring to No. 4 of the other. The C-C distance is 1.5 A. U., the C-O distance 1.2 A. U. The length of the two joined rings is 10.3 A. U., agreeing with the x ray identity period along the fiber axis. The cellobiose residues are thus joined

by an O bridge from unit cell to unit cell, the axis of the chain thus formed being the fiber axis, which from the geometry of the model must be a two-fold screw-axis. In the monoclinic system C_2^2 is a satisfactory space-group from the standpoint of the model; for the special case where the planes of the hexose rings are parallel to the a axis (8.7 A. U.) the proper axial ratios and good agreement with observed x-ray intensities result. In this cell the cellobiose chains are arranged along the (010) edges, and the (010) axis in the center, of the cell; (010) is a polar direction. In the rhombic system V^3 and V^4 are in agreement with the x-ray intensities and axial ratios but (010) is not polar. Mercerized cellulose shows a diagram of a unit cell shorter along the fiber axis and larger in the other directions. A turning of the cellobiose chains about the fiber axis through an angle of approx. 45° , half clockwise and half counter-clockwise, supplies an arrangement which agrees with the x-ray data. The lateral expansion of the cell indicates a weaker bond between parallel cellobiose chains than in native cellulose and hence explains the greater reactivity of the mercerized product. Alkali-cellulose diagrams indicate that the alkali penetrates into the voids in the cellulose lattice, causing the changes noticed in the mercerized diagram. Completely nitrated cellulose shows a simple fiber diagram, somewhat similar to that of cellulose. There are no distinct diagrams corresponding to the mono- and di-nitrates. The diagrams of a nitrated cellulose of 7-12% N may either show both the cellulose and tri-nitrate patterns or no distinct pattern at all, depending upon the conditions of nitration. In the first case some fibers have been completely nitrated while others are not affected; in the second all fibers are partly nitrated. The acid is apparently taken into the lattice, causing some distortion, until sufficient is present for the complete nitration when a new sharply defined lattice is formed, which is closely related to the original. In this view of the structure of cellulose the masses osmotically, etc., effective in solns. are not mols. in the usual sense, but particles or micelles made up of cellobiose chains, arranged in parallel and held together by inter-micellar forces, which are similar in nature to van der Waal forces. The great tensile strength in the fiber axis direction of cellulose fibers is due to the primary valence structure of the cellobiose chains. The strength in lateral directions indicates a strong inter-micellar force, as might be expected from the length of the chain and the known strong attraction of OH groups (e. g., in H_2O and the alcohols). The increased solubility of cellulose nitrates and acetates may be due to the replacement of the OH groups and the consequent weakening of the attractive forces. The breadth of the x-ray interference lines and diffusion coefficients indicate about 1500-2000 glucose residues per micelle. 40-60 cellobiose chains each having 30-50 glucose residues is approx. the constitution of a micelle. Whereas alkalis penetrate the lattice without rupturing the O linkages of the chains, acids do cause such rupture and induce decomposition, simultaneously weakening the inter-micellar forces, which depend upon the chain length. A series of decomposition products from cellulose to glucose might be expected and are obtained as a result of this chain breakage. Coagulation of solns. of cellulose or its esters is not a true recrystn. in the sense that new lattice units are built up during the coagulation. The strength of the products is increased if the dissolved particles are forced to assume a parallel arrangement, apparently bringing the inter-micellar forces into play, but no new O linkages along cellobiose chains are established. This primary valence linkage into long chains may be expected to be characteristic of a number of natural compds. R. I. H.

Action of reagents upon cellulose. CHAS. E. MULLIN. Clemson College Textile School. *Textile Colorist* 50, 92-4; *Textile Weekly* 2, 437-8(1928).—A review of the effects of the various more common reagents upon cotton, linen, rayon (except acetate), etc. CHAS. E. MULLIN.

The nature of nitrocellulose. H. BRUNSWIG. *Z. ges. Schiess-Sprengstoffu.* 23, 337-40, 384-7(1928).—Convincing arguments are presented to show the fallacy of the claim of Herzog and von Naray-Szabó (*C. A.* 22, 4244), based on x-ray studies, that the various cellulose nitrates are simply mixts. of the trinitrate and unchanged cellulose. In the examn. of many hundreds of samples of nitrocellulose, B. has found none with any appreciable content of unchanged cellulose. The existence of a heterogeneous chem. equil. between product and nitrating acid is shown by the fact that products of the same chem. and phys. properties (% N, soly., hygroscopicity, etc.) result from either nitration or denitration under appropriate conditions, as in examples cited. The rate of decompn. of nitrocellulose shows no linear relation to its N content, as would be the case in a mixt. of trinitrocellulose and unchanged cellulose. A product of 13% N requires long boiling with H_2O for stabilization, while one of 11% N can be stabilized to an equal degree by mere washing at room temp. The relation is undoubtedly an exponential one, indicating that cellulose nitrates of different N content are

mixts. of unlike components. Both N content and soly. are functions of the compn. of the nitrating acid at completion of the nitration. This depends upon both the original compn. and the ratio of cotton to acid mixt. The results of numerous expts. showing the effects of variations in these factors are tabulated and plotted. A "gelatin cotton" of 12.25% N was dissolved in Me_2CO (1% soln.) and pptd. in 3 fractions by successive addns. of H_2O . The N contents of the fractions were 12.43, 12.28 and 11.92%. The 2nd fraction was repptd. into 2 portions of 12.34 and 12.15% N. C. G. STORM

Steamed straw—a new process for the conversion of straw. JANATA. *Wochbl. Papierfabr.* 59, 978-81(1928).—An exposition of German patent 413,285. Straw is steamed without the addn. of chemicals at about 5 atm. pressure for 2 to 4 hrs., broken up in kollergangs and finally beaten in hollanders. The yield is some 67% of a dark brown pulp, relatively free from lignin, and about twice the strength of ordinary lime-cooked straw pulp. Possible new uses are enumerated. **Steamed straw.** RIEFGERSTE. *Ibid* 1241-3.—A patented process of the Berlin Gesellschaft für mechanische Cellulose, which is similar to that of the foregoing abstract, is described. The small amt. of waste liquor obtained by pressing the steamed straw may be used as sizing agent, dyestuff or cattle feed. R. H. DOUGHTY

Viscose—fibers, pulp, gel and filaments. JAMES SCOTT. *Silk J.* 5, No. 49, 67-8(1928).—A discussion of the microscopy of these products. C. E. M.

Manufacture of viscose silk with special regard to the dyeing properties. H. F. CROW. *Silk J.* 5, No. 50, 54, 66(1928).—The affinity of rayon for dyestuffs is largely a phys. property and therefore the phys. form of the thread is quite as important as its chem. constitution. The properties of viscose depend on a variety of factors from the kind of pulp used to the temp. of the factory. Pulp shipments should be checked regularly and the Cu number should be below 0.3 or the fastness of the colors on the rayon may be impaired. The methylene blue absorption factor gives a clue as to the evenness of dyeing and a low figure is desirable. Uneven caustic impregnation of the pulp causes uneven dyeing rayon, just as does uneven mercerization on cotton. Experience indicates that a low temp. in aging the crumbs gives a more level dyeing silk. Viscose which has been ripened for only a short time gives a silk dyeing heavier than that from a ripper viscose, but the colors are brighter on the latter. The ripper viscose gives threads of lower elasticity and it has been noticed that as the elasticity of the threads grows less, so does the dyestuff affinity, and this applies equally well to the products of different manufacturers. The temp. and concn. of the spinning bath are also important for even dyeing silk. But in spite of all of the above, the majority of dye-house faults are caused by the mechanical processes through which the silk passes in the finishing department. Great care is necessary in reeling the damp cakes into hanks as the wet fiber has little strength or elasticity, so that if the tension varies, with uneven stretching, uneven dyeing will result. Inefficient desulfurization may also cause uneven dyeing, as well as dull and yellow rayon. Bands in woven fabric caused by uneven steaming during finishing may be removed by rewetting the goods, but if caused by uneven yarn or defects in knitting, they cannot be removed. If strain has occurred after dyeing, bright spots will appear running across the fabric. If the strain occurred before dyeing, the dyestuff is taken up unevenly. Rayon oils, sizing and scouring are also discussed. CHAS. E. MULLIN

Denitration in the manufacture of rayon from nitrocellulose. A. NADAI. *Z. physik. Chem.* 136, 289-313(1928).—A study of the reaction velocity of the denitration of nitrocellulose with NaSH shows that this process can be expressed as a reaction of the first order although it occurs in a heterogeneous system. Temp., concn. of soln., and addn. of swelling agents influence velocity analogous to that of a homogeneous reaction. Alc. up to 1% increases velocity, 1.5% giving no further increase. NaSH becomes oxidized by the NO_2 to polysulfides, simultaneously the NO_2 being reduced to NO and NH_3 . The NH_3 catalyzes the denitration. Addn. of NaNO_2 increases this autocatalysis. NaNO_2 was not detected in the reaction liquor. F. C. H.

Manufacture of fine-fiber artificial silk. ADOLF HILRINGHAUS. *Silk J.* 4, No. 48, 54-5(1928).—A brief discussion of the method of manuf. and some of the patents. CHAS. E. MULLIN

The manufacture of acetate silk. CHAS. E. MULLIN. *Silk J.* 4, No. 46, 49-50; No. 48, 50; No. 49, 62; No. 50, 51-2(1928).—A discussion of the patents and literature upon the manuf. and properties of cellulose acetate and its conversion into acetate silk. CHAS. E. MULLIN

Acetic acid. Its recovery in the manufacture of acetate silk. J. L. GENDRE. *Rev. chim ind.* 37, 378-82(1928).—A review of the present methods in use and others not commercially developed. P. THOMASSET

Cellulose (Hess, *et al.*) 10. Substances accompanying cellulose (Hess, *et al.*) 10. Survey of the important kinds of plastic masses (Schmidt) 18. Cellulose ester solvents (Wolff, *et al.*) 26. Wise, Louis F.: *Chemical Treasures of the Forest*. Washington, D. C.: The Am. Forestry Assoc. 28 pp. Reviewed in *J. Chem. Education* 5, 1712(1928).

Cellulose. CHARLES HARNIST. Ger. 469,372, July 9, 1920. See Brit. 156,777 (C. A. 15, 1811).

Cellulose. WOLFF & Co. KOMMANDIT-GESELLSCHAFT AUF ACTIEN AND RICHARD WEINGAND. Fr. 642,176, Oct. 11, 1927. See Brit. 289,997 (C. A. 23, 703).

Cellulose from beechwood. HERMANN SUIDA and HANS SADLER. Austrian 111,385, July 15, 1927. Cellulose suitable for the manuf. of artificial silk is prepd. from beechwood by treatment at a temp. not exceeding 85° with a dil. mixt. of HNO₃ and H₂SO₄ contg. 15-25% HNO₃ and less than 10% H₂SO₄, followed, after removal of excess acid, by treatment with 9% alkali lye

Method for obtaining cellulose from wood, straw and other vegetable materials. G. S. PETROV, N. L. ALEKSEEV and V. Y. RYABTZOVSII. Russ. 4590, Feb. 29, 1928. The alk. soln. used with the above materials is mixed with high mol. sulfonic acids from crude oil hydrocarbons and phenol.

Cellulose articles. CHARLES ZARFEL and WILLY DESIRÉ STROEVER. Fr. 641,573, Sept. 20, 1927. Waste products, lignified vegetable fiber, spent tan and crude bark are boiled for several hours in a closed vessel with a caustic lye contg. 3-4% of the wt. of the material in alkali, the mass being freed from lye, washed and molded into articles. The hardness of the mass may be increased by adding paper fiber.

Cellulose compounds. I. G. FARBENIND. A.-G. Fr. 642,220, Oct. 13, 1927. Cellulose is rendered more easily convertible into ethers or esters by a treatment before or during conversion with softening agents such as propylnaphthalenesulfonic acid or higher substituted derivs. thereof or their salts. Examples are given of the prepn. of viscose, nitrocellulose and alkali-cellulose.

Treating cellulose compounds. CAMILLE DREYFUS. Fr. 642,628, Oct. 20, 1927. Artificial silk contg. cellulose acetate or other org. deriv. of cellulose is treated with a swelling agent such as HCOOH, AcOH, PhOH, pyridine, etc., and then with a weighting agent such as SnCl₄ or ZnCl₂, or the swelling agent may be added to the bath contg. the weighting agent. The weighting agent may be used in such concn., *e. g.*, a soln. of SnCl₄ of sp. gr. 1.2, that it acts as a swelling agent.

Cellulose derivatives. I. G. FARBENIND. A.-G. Fr. 641,043, Sept. 16, 1927. Sol. derivs. of aminocellulose are prepd. by treating cellulose esters from organically substituted inorg. acids with an acid chloride or acid anhydride in the presence of a tertiary aliphatic aromatic or aralyphatic amine; or by esterifying or etherifying in either order and treating with a primary, secondary or tertiary amine. In examples, cellulose-toluene-4-sulfoacetate, from acetylcellulose and toluene-4-sulfochloride, is heated with isoamylamine, di- or tri-ethylamine, diphenylamine or PhNMe₂. Alkali cellulose is esterified with benzenesulfochloride, acetylated and heated with PhNH₂. Cellulose-toluene sulfonate is boiled with pyridine and BzCl. The products have a pronounced affinity for acid colors. They may be converted into threads or films which are easily dyed in fast tints, and if added to cellulose esters or ethers they render the latter more easily dyed. Cf. C. A. 23, 703.

Thin foils of soluble cellulose derivatives. CELLON-WERKE ARTHUR REICHENGRUN. Ger. 469,317, Aug. 11, 1922. A soln. of one cellulose deriv., especially an ester or an ether, is spread on a base composed of another cellulose deriv. which is not easily sol. in the solvent.

Treatment of cellulose derivatives. HENRY C. OLPIN (to Henry Dreyfus). Can. 285,979, Dec. 25, 1928. Materials comprising cellulose acetate and an animal or a cellulosic fiber are dyed in solid or differential effects, by applying thereto a sulfuric ester of an anthraquinonylamino alc. in the form of an alkali salt thereof.

Treatment of cellulose derivatives. HENRY DREYFUS. Can. 285,800, Dec. 25, 1928. Goods made of or contg. cellulose esters of org. acids which are homologs of AcOH are loaded with a metallic salt or salts by treatment in succession with a bath

contg. in soln. a salt or salts of a metal or metals such as Sn, Zn, W or Al and a bath contg. a soln. of phosphate, silicate, tannin or other compd. or compds. adapted to deposit the metal or metals as an insol. salt or salts or compd. or compds. upon the goods. The loading operation may be repeated as it increases the capacity for absorbing dyestuffs. The goods, after loading, may be dyed with direct acid, basic or other dyestuffs.

Treatment of cellulose derivatives. HENRY DREYFUS. Can. 285,801, Dec. 25, 1928. Material comprising ethyl cellulose is dyed with an aq. dispersion of a relatively water-insol. coloring compd. prepd. by pretreating the compd. with a solubilizing agent comprising a Na salt of sulforicinoieic acid.

Weighted cellulose compounds. HENRY DREYFUS. Fr. 642,331, Sept. 16, 1927; Can. 285,802, Dec. 25, 1928. Cellulose derivs. in the form of artificial silk, etc., are weighted with metals, e. g., Sn, partly or wholly in the form of thiocyanate. Examples are given of treatment with solns. contg. SnCl_4 and NH_4CNS in proportions suitable for the formation of $\text{Sn}(\text{CNS})_4$, $\text{SnCl}(\text{CNS})_3$ and $\text{SnCl}_2(\text{CNS})_2$. The material may be treated afterward with a soln. of phosphate.

Preparing cellulose for esterification. HENRY DREYFUS and CLIFFORD I. HANEY (to Celanese Corp. of America). U. S. 1,697,907, Jan. 8. Cellulosic material is preliminarily treated with a small proportion of formic acid, which renders it highly reactive for esterification, e. g., with acetylating reagents.

Cellulose esters. I. G. FARBENIND. A.-G. Brit. 291,360, May 30, 1927. Cellulose esters of lower aliphatic acids are prepd. by treating the cellulosic material with a halide of a lower aliphatic acid such as acetyl chloride in the presence of an org. base such as pyridine and an "indifferent" org. medium such as PhCl which at least partly dissolves the addn. product of acid halide and org. base formed in the esterification mixt. but which is not a solvent of the cellulose ester which is produced.

Cellulosic esters containing bromine-substituted stearic acid groups. HANS T. CLARKE and CARL J. MALM (to Eastman Kodak Co.). U. S. 1,698,049, Jan. 8. Cellulosic material such as cotton or bleached sulfite pulp is treated with an esterifying bath contg. Br-substituted stearic acid and chloroacetic anhydride. The product is suitable for making non-inflammable films.

Soft and pliable masses from cellulose esters. OSKAR LOEHR (to I. G. Farbenind. A. G.). Can. 285,919, Dec. 25, 1928. A compn. of matter contains a cellulose ester and an ester of a polyethylene glycol with an aromatic carboxylic acid. The product is suited to the manuf. of plastic masses, lacquers, artificial leather, etc. Example: Dissolve 16 parts by wt. of acetylcellulose together with 8 parts by wt. of a mixt. of the benzoic acid esters of a mixt. of polyethylene glycols consisting essentially of diethylene glycol b_{15} from 230° to 260° and contg. no free OH group, in 50 parts by wt. of acetone and 20 parts by wt. of cyclohexanone. The soln. on pouring and evapg. the solvent yields a film of excellent properties.

Plastic cellulose compositions. SOC. CHIMIQUE DES USINES DU RHÔNE. Swiss 127,543, June 24, 1927. Plastic and finely divided compns. are prepd. from cellulose esters by adding an adjuvant to the soln. of the ester. A coloring matter may also be added. Thus, ultramarine blue and ethyl-*p*-toluenesulfonamide are added to a soln. of cellulose acetate in acetone. The cellulose acetate is then pptd. and washed. Other examples are given.

Plastic substances in powder form. SOCIÉTÉ CHIMIQUE DES USINES DU RHÔNE. Fr. 333,066, Feb. 22, 1927. Addn. to 622,733. Plastic substances having a basis of cellulose ether are obtained as a powder by dissolving them in a solvent and adding a liquid precipitant which does not dissolve the plastic substance, but is miscible with and less volatile than the solvent, and distg.

Moldable powders containing cellulose esters and ethers, etc. A. EICHENGRÜN (trading as Cella-Werke, Dr. A. Eichengrün). Brit. 290,989, May 20, 1927. Compns. contg. viscous solns. of cellulose derivs. such as esters or ethers, with or without addnl. substances such as softening agents, fillers, resins, dyes, artificial resins, rubber, etc., are pressed through narrow apertures in a highly heated state so that the issuing mass swells and the solvent evaporates, leaving a dry brittle product which may be easily disintegrated into a powder suitable for molding.

Cellulose acetates. A. WACKER GES. FÜR ELEKTROCHEMISCHE INDUSTRIE GES. Brit. 291,001, May 23, 1927. Cellulose acetates sol. in CHCl_3 and of high viscosity and good mech. properties are obtained with use of ZnCl_2 as catalyst by carrying out the first phase of the acetylation at an elevated temp. (suitably 55 – 60°) and the second phase at a lower temp. (suitably about 40°). An "indifferent" liquid such as benzene may be added to the acetylation mixt.

Sheets, filaments or other forms from cellulose acetate or other cellulose derivatives. A. EICHENGRÜN. Brit. 291,386, May 31, 1927. The material is caused to swell by use of a liquid which is a non-solvent or acts as a solvent only when heated or of a mixt. of a non-solvent with only a small proportion of a solvent. A doughy plastic mass is formed which can be made into molded articles, sheets, films or filaments, with or without addn. of fillers, artificial resins, etc. Several examples are given.

Cellulose acetoöleate. HANS T. CLARKE and CARL J. MALM (to Eastman Kodak Co.). U. S. 1,698,048, Jan. 8. Partially deacetylated cellulose acetate is treated with an esterifying bath including chloroacetic anhydride and oleic acid. The product obtained is suitable for making films. Other similar esters also are referred to.

Nitrating cellulose. M. G. MILLIKEN (to Hercules Powder Co.). Brit. 291,082, May 28, 1927. An app. is described in which cellulose is passed through a body of nitrating acid in which it remains submerged until the desired degree of nitration is effected.

Nitrocellulose. I. G. FARBENIND. A.-G. Fr. 640,087, Aug. 27, 1927. Cellulose is heated with water under pressure to 140–170° for a prolonged time to obtain any desired viscosity of solns. in the usual solvents of nitrocellulose made from this cellulose. Cellulose heated for 6 hrs. in this way gives a nitrocellulose with 0.1 the viscosity of ordinary nitrocellulose. Cf. C. A. 23, 703.

Cellulose solutions. I. G. FARBENIND. A.-G. Fr. 641,685, Sept. 30, 1927. Ammoniacal CuO solns. of cellulose are prepd. by using the cellulose in the form of paper.

Cellulose wadding. JULIUS RICHTER. Austrian 109,878, Feb. 15, 1928. A cellulose pulp is dried in a loose unpressed state. The drying may be effected on perforated bands with warm air, if necessary with application of suction.

Manufacture of cellulosic products. ERNEST MULLER. Swiss 127,275, May 30, 1927. In the manuf. of cellulosic products by coagulation from solns., particularly in the manuf. of films from viscose, a softening agent is added only during the drying stage, and preferably toward the end of that stage.

Sugars from cellulosic materials. Soc. D'ÉTUDES CHIMIQUES POUR L'INDUSTRIE. Swiss 127,238, April 25, 1927. Fermentable sugars, not intended for human consumption, are obtained by boiling cellulosic materials with dil. mineral acids, first at ordinary pressure and then at 150° under increased pressure.

Synthetic materials. LEON LILIENFELD. Ger. 467,003, May 20, 1924. Prior Austrian application April 4, 1924. *N-Alkyl thiourethans of cellulose* with or without other colloids, plasticizers, pigments, fillers, etc., in alk. soln. are ppt. with a suitable precipitant. A similar soln. of the cellulose deriv. and its admixtures in a volatile solvent may be dried. The process yields *plastics, paints, lacquers, artificial silk, cements, textile and paper sizes and coatings, waterproofing agents, artificial leather, linoleum substitutes, electric insulators and bookbinding material.*

Treating cork with esterifying reagents. I. G. FARBENIND. A.-G. Brit. 291,773, June 8, 1927. Cork is suspended in an inert vehicle such as PhCl and caused to react with reagents such as are used for esterifying cellulose, *e. g.* with Ac₂O or lauryl chloride in the presence of pyridine or POCl₃ in the presence of pyridine. The products are plastic under pressure and when heated.

Viscose. LOUIS CHARLES PHILIPPE JARDIN. Fr. 641,868, Mar. 5, 1927. Cellulose in any form is transformed into defibered alkali cellulose by a simultaneous cutting and wetting with the calculated amt. of NaOH soln. The app. may consist of a vat contg. rotating screws and a fixed cutting piece between which the cellulose is torn.

Viscose. LOUIS CHARLES PHILIPPE JARDIN. Fr. 641,866, Mar. 4, 1927. Sheets of cellulose pulp are transformed into alkali cellulose by intimate and homogeneous impregnation with a soln. of NaOH which is determined beforehand to correspond exactly with the amt. necessary for the transformation. The sheets are freely suspended in a frame which can be immersed in a steeping vessel and raised again for washing.

Artificial silk. I. G. FARBENIND. A.-G. Swiss 126,778, June 28, 1927. A device for receiving spun artificial silk is made of a durable alloy impervious to acids, especially HNO₃. A suitable alloy contains Fe, Cr, Ni and Mo.

Artificial silk. I. G. FARBENIND. A.-G. Swiss 127,493, Apr. 29, 1927. In spinning artificial silk from cuprammonium solns. of cellulose, a pptg. bath contg. free CO₂ is used. An aq. soln. of CO₂ is suitable. Cf. Brit. 289,942 (C. A. 23, 982).

Artificial silk, etc. KIKUCHIKO HAGIWARA (to Toshiya Iwasaki). U. S. 1,699,615, Jan. 22. In forming artificial silk and like filaments from viscose or similar materials, an elec. current (suitably an induction current) is passed between electrodes, one of which is in a soln. of the raw material and another in the coagulation bath, in order to

accelerate flow through the spinning nozzle and decompose S compds. Cf. C. A. 23, 705.

Perpendicular spinning device for artificial silk and other artificial threads. C. G. HAUBOLD A.-G. Ger. 469,345, Feb. 5, 1927. Details of arrangement.

Digesting fibrous material. THOMAS L. DUNBAR and AUGUST F. RICHTER (to Chemipulp Process, Inc.). U. S. 1,699,056, Jan. 15. Fibrous material such as wood chips is digested with acid liquor and high pressure existing in the digester during a portion of the cooking period is utilized for discharging heated high-pressure gas and vapor from the digester during that portion of the cooking period and for introducing the same in its heated condition into acid liquor in an accumulator; suction is exerted on the digester during another portion of the cooking period to withdraw heated low-pressure gases and vapors from the digester and these low-pressure gases and vapors are contacted while heated with a flowing stream of acid liquor; acid liquor thus pre-conditioned, from the accumulator and flowing stream, is utilized for digesting fibrous material. An arrangement of app. is described.

Calcium bisulfite liquor. RICHARD BÖHLIG. Ger. 464,262, July 26, 1928. $\text{Ca}(\text{HSO}_3)_2$ liquor contg. 1–5° Bé. of SO_2 is prepd. by treating lumps of CaO with water and SO_2 in a rotating app. contg. iron balls, the purpose of these being to expose fresh surfaces of the lime.

Sulfite pulp. GEORGE H. TOMLINSON. U. S. 1,697,032, Jan. 1. Hot liquor discharged with the cooked pulp from a digester into a blow-pit is used to preheat and to wash into position a second charge of chips in the digester and there is mixed with the second charge a quantity of cooking acid which has been preheated by the fluid passing through the relief valve of the digester while the first-mentioned charge of pulp was undergoing cooking. Cf. C. A. 22, 4247.

Sulfite cellulose lye. Soc. BARBOU ET CIE. Fr. 642,270, Jan. 21, 1927. The waste liquor from the treatment of cellulose with Na_2S is treated with H_2SO_4 to convert the sulfonated org. content into Na_2SO_4 with the ptn. of the org. substances and liberation of SO_2 . Na_2S is reformed and used again.

Treatment of residual liquor. PIERRE A. BARBOU (to Soc. Barbou et Cie). Can. 285,952, Dec. 25, 1928. The lye or liquor accruing from the boiling of vegetable matter with Na_2SO_3 is treated with lime at 75° in an open or closed container. The mixt. so formed is agitated and then allowed to stand. After leaving the mixt. for 24 hr. the liquid supernatant on the ppt. is drawn off and transferred to a further open or closed container. The correct amt. of calcium bisulfite soln. is now added to the liquor. The mixt. is then agitated for a few min. and allowed to stand. After an hour the clear supernatant liquid is drawn off and neutralized with NaOH to obtain a soln. of NaSO_3 which may be used for further lixiviating operations.

Treatment of black or brown liquors from sodium sulfate-cellulose manufacture. FRITZ WALLENBERGER. Austrian 110,272, Mar. 15, 1928. The liquors are treated in a closed container with a mineral acid or acid salt, the H_2S being drawn off and absorbed in NaOH soln. in a closed system.

Recovery of caustic soda. GIUSEPPE DONAGEMMA. Fr. 641,901, Mar. 12, 1927. The water used in the dialyzers for the recovery of NaOH solns. used in *alkali cellulose* manuf. has 1 to 2% of NaOH added to it to prevent crust formation on the diaphragms.

Dialyzer diaphragm. GIUSEPPE DONAGEMMA. Fr. 641,886, Mar. 11, 1927. Diaphragms used for the recovery of NaOH solns. used in *alkali cellulose* manuf. are made of natural stone having a micro-granular structure by cutting from a single block of stone having no chem. reaction with NaOH or fragments of stone cemented together with a binding agent.

Treating strawboard waste. JOHN T. TRAVERS (to Travers-Lewis Process Corp.). U. S. 1,699,257, Jan. 15. Waste such as the fluid wastes from strawboard manuf. is initially subjected to the action of CaSO_4 and $\text{Ca}(\text{OH})_2$, the pptd. material is permitted to settle, the effluent is removed and the removed effluent is treated with a mixt. contg. mono- Ca phosphate (such as a mixt. also contg. waste cement dust and FeSO_4) in order to effect coagulation.

Treating sulfite pulp waste. JOHN T. TRAVERS (to Travers-Lewis Process Corp.). U. S. 1,699,258, Jan. 15. Sulfite pulp mill waste is permitted to stand quiescent in a settling zone to permit suspended matter to settle out, and the liquid waste thus sepd. from substantially all the suspended matter is then passed through porous CaCO_3 and maintained in contact with the CaCO_3 for about 2 min., in order to clarify the effluent.

Treating waste sulfite liquor. ERIK L. RINMAN. U. S. 1,699,808, Jan. 22. The waste liquor is evapd. and combustion of its combustible matter is then effected in

such a manner that the Na compds. present are converted into Na sulfide and soda; the combustion residue is dissolved in water and treated with an oxide of a metal such as ZnO, the S compds. of which are insol. in NaOH soln. so that all the Na_2S is transformed into NaOH; the sepd. soln. is then treated with SO_2 to produce fresh digester liquor.

Treating waste sulfite liquor. GUY C. HOWARD. U. S. 1,699,845, Jan. 22. An alk. soln. of sulfite liquor from which the major portion of the Ca ligninsulfonic acid constituent has been previously decomposed and removed is treated with an excess of a solid reagent such as lime to effect complete decompn. and removal of the residual ligninsulfonic acid and the ppt. and associated solid reagent thus formed are used together in treating a further quantity of the liquor to effect removal of the major portion of its Ca ligninsulfonic acid constituent.

Paper-making apparatus. HAROLD F. DUNBAR. U. S. 1,698,189, Jan. 8.

Suction box for paper-making apparatus. ARCHELAUS LEWIS. U. S. 1,696,917, Jan. 1. Structural features.

"Beating engine" for treating paper pulp. J. WHITE. Brit. 291,173, March 9, 1927. Structural features.

Paper pulp by the acid sulfite process. ROBERT B. WOLF. U. S. 1,699,556, Jan. 22. An app. is specified comprising a digester and acid liquor storage tanks and an absorber, arranged for circulation of the contents of the storage tanks through the absorber; a connection is provided for delivering gas from the digester to the absorber, and a separator for moisture and fiber is interposed between the digester and absorber.

Apparatus for separating impurities from fluent aqueous paper pulp by gravity and straining. S. MILNE. Brit. 291,154, Feb. 25, 1927.

Plant for semi-continuous digestion of cellulose or paper pulp from bamboo, etc. EXECUTORS OF BARON CABLE, G. C. GODFREY, F. C. BENTHALL, E. S. TARLTON and H. F. WHEELER (trading as Bird & Co.) and E. SPENCER. Brit. 291,064, May 28, 1927. A plant is specified which is adapted for carrying out processes such as described in Brit. 283,910 (C. A. 22, 4248) in which the digesting liquor after use in any one digester is passed to the digester next-but-one lower in the cycle of operative sequence. Brit. 291,065 specifies a semi-continuous progressive process for prepn. of cellulose or paper pulp from bamboo, grasses, wood or reeds by digestion under a gradually increasing pressure and digesting liquor concn. and in which the liquor concn. in the last stage or the compn. of the liquor, and if desired also the pressure in the final stages, may be so reduced or modified as to render its action less severe and thus avoid hydrolysis of the fiber. Mixed digesting liquors may be used such as caustic alkali, sulfides and sulfites with a greater proportion of the latter during the later stages of the process.

Tank and mixing devices suitable for treating wet paper stock. JOSEPH A. WHITE (to Grellet Collins). U. S. 1,696,994, Jan. 1. Structural features.

Centrifugal apparatus for purifying paper-making material. HERMANUS THOMASSEN. Ger. 469,318, Apr. 8, 1923. Description of method and app.

Manufacture of fibrous materials. EMIL CLAVIEZ. Ger. 469,393, Apr. 12, 1925. Fibrous husks, *e. g.*, of the coconut, are subjected to the same grinding and other treatments as are applied in prepn. wood fibers.

Waterproofing fibrous materials or paper. E. I. ORLOV. Russ. 4821, Mar. 31, 1928. The above materials are impregnated with a Reinicke salt, *e. g.*, $[\text{Cr}(\text{NH}_3)_4(\text{SCN})_2]\cdot\text{NH}_4(\text{K},\text{Na})$ or a Morland salt, *e. g.*, $[\text{Cr}(\text{NH}_3)_2(\text{SCN})_4]\cdot\text{H}\cdot\text{NH}_2$ and

preliminarily heated with neutral salts until the color of the soln. changes from purple to violet. These operations are followed by drying with heat, washing and drying again.

Waterproof straw pulpboard. EDWARD B. WESTON and WILLIAM G. CLARK (to Terre Haute Paper Co.). U. S. 1,697,702, Jan. 1. Pulpboard is formed from straw fibers substantially free from alkali and having a rosin size incorporated with them.

Means for tightening loosely wound paper rolls. FREDERIK SCHADE. Ger. 469,676, July 12, 1927.

Apparatus for making coreless rolls of paper, etc. CARL NEBRICH. Ger. 469,675, July 13, 1927.

Carbon or duplicate paper. FELIX PELTZER & Co. Swiss 127,545, Mar. 7, 1927. Details of prepn. of the colored layer.

Manufacture of pasteboard. "CARINTHIA" PAPPENFABRIKEN GUSTAV HORNBORG & Co. Austrian 110,727, May 15, 1928. The manuf. of a uniformly thick product is

facilitated by measuring micrometrically the distance between the rollers, or the spindles of the rollers, from which the damp sheet is delivered.

Felt paper. PIERRE DREWSSEN (to The Barrett Co.). Can. 285,687, Dec. 18, 1928. Felt paper is produced by blending flax tow fibers which have been cooked by a pentasulfide process with felt paper-making material which has high satg. qualities and forming a sheet of felt paper contg. said components.

Felt. PIERRE DREWSSEN (to The Barrett Co.). Can. 285,686, Dec. 18, 1928. Cordage fibers are placed in a paper mill beater with hot water maintained at 90° to 100°, to which strong alkali, such as NaOH, or Ca(OH)₂, etc., has been added to approx. 10% by wt. of the raw fibrous substance used. Live or exhaust steam is used for heating. The time of treatment varies with the strength of alkali used and nature of the fibrous substance. Before the fiber produced in this manner is used for paper making it is washed to remove the chemicals, in order to avoid difficulties in the subsequent paper-making operations.

Apparatus for forming bottles, cups, plates, etc., from paper pulp. EUGENE P. KENNEDY. U. S. 1,697,244, Jan. 1. A mold is passed through a pulp vat and then through a drying chamber in both of which continuous suction is maintained on the mold.

Baking pan. OTTO HERTING (to Sani Paper Products Co.). U. S. 1,699,843, Jan. 22. A pan suitable for baking pies is formed of wood or vegetable pulp or other suitable fibrous material impregnated with substances such as those which may be formed by the interaction of Al₂(SO₄)₃, Ti sulfate, Na tetraborate and Na silicate. U. S. 1,699,844 specifies similar impregnated utensils, the inner surface of which is coated with paraffin of high m. p. and carnauba wax.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

Present situation of the question of mercury fulminate substitutes. F. BLECHTA. *Chem. Obzor* 3, 330 6(306 English)(1928).—The fulminates of other metals, PbN₃, and other azides, diazo compds., Pb salt of methylenediisonitramine, and cyanuric triazide, though many of them possess greater initial igniting acceleration, have proved to be either too sensitive or too unstable for practical use. JAKOSLAV KUČERA

Ignition of mixtures of air with natural gas and with methane by induction-coil sparks. E. G. MEYER. *Ind. Eng. Chem.* 20, 1353-4(1928).—The U. S. Bureau of Mines uses natural gas rather than methane for producing explosive atms. for its investigations of the safety of mining equipment and of explosives. A knowledge of the relative inflammabilities of mixts. of air with each of the two gases is important because the flame properties have been considered approx. the same. The app. and method have been described by Sastry, Wheeler, Coward and Meier (*C. A.* 10, 2149; 11, 1596; 14, 3157; 21, 1185-6). The results show that the most sensitive mixt. of a natural gas (CH₄ 88.9, C₂H₆ 7.4, C₃H₈ 2.4, C₄H₁₀ 0.8, higher hydrocarbons 0.1, N₂ 0.1%) and air is more easily ignited by an induction-coil spark than the most sensitive mixt. of CH₄ (natural and with less than 2% impurity; purified) and air; but the difference is small. The use of natural gas instead of CH₄ for testing the safety of elec. machinery in explosive atms. is therefore on the side of safety. The most readily ignited mixts. of natural gas and air, under the conditions used, are those which contain between 7.3 and 8.6% natural gas. A. J. MONACK

Determination of sensitiveness to friction of priming compositions. H. RATHSBURG. *Z. angew. Chem.* 41, 1284-6(1928).—No reliable method of expressing numerically the sensitiveness to friction of priming compns. is known. The falling wt. test is only a compromise. A steel pestle rotating at 80 r. p. m. pressed by definite loading wts. on priming compn. contained in a porcelain or steel mortar gives definite, reproducible results. E. M. SYMMES

The continuous nitroglycerin process of Dr. Arnold Schmid as installed at Brig. GOTTFRIED VON FRILITZEN. *Z. ges. Schiess-Sprengstoffw.* 23, 343-4(1928).—The app. installed in the Swiss plant at Gamsen-Brig has a vol. of only 25 l., but produces 100 kg. C₃H₅(ONO₂)₃ per hr. (cf. *C. A.* 21, 4070). Its many advantages over the batch process from the standpoint of safety are discussed (cf. *C. A.* 22, 3047), and the process is fully indorsed. C. G. STORM

The initiation and propagation of explosion and the testing of detonators, based on foreign reports. HAID AND GLOBIG. *Z. ges. Schiess-Sprengstoffw.* 23, 302-5, 350-2 (1928).—The authors review the various published articles on the influence on rate

of detonation in high explosives of such factors as diam. of charge, confinement, temp., cryst. size, aging of gelatin dynamite and strength of detonators. The limitations of various tests proposed for detonators are discussed (cf. C. A. 10, 1930; 16, 4347; 21, 3270). C. G. STORM

Fighting dust explosions. HYLTON R. BROWN. *Pit and Quarry* 7, 74-5(1928).—The use of inert gases properly introduced into the dust producing or conveying system is discussed. In planning for this there must first be known (1) quantity of air which normally enters the machine or systems, (2) reduction of O necessary to prevent explosions of the materials being handled, (3) percentage of O, if any, in the gas used to create the inert atm., (4) quantity of gas required, (5) availability of the required quantity of gas, (6) type of gas-conditioning equipment, if necessary, (7) the type of gas-distributing system best adapted to the plant. By giving consideration to these important points on planning the protective system accordingly it is possible to eliminate from the most hazardous points in industrial plants all danger of dust explosions.

CHARLES E. MUNROE

Evaluation of stibnite (McNABB, WAGNER) 7. The spontaneous ignition of benzene (TROTMAN) 25.

Explosive. ALEXANDER C. SCOTT (to Mexico, Ltd.). U. S. 1,700,085, Jan. 22. Particles such as those of KClO_3 or like compds. are isolated from each other by a synthetic resin which forms a continuous phase between the particles.

Black powder. LIGNOZA S. AKCYJNA. Fr. 641,442, Aug. 23, 1927. C in black powder is replaced by hydrocarbons such as C_{10}H_8 , sulfo acids of C_{10}H_8 or of phenols, or nitrosulfo acids of phenols. Carbohydrates such as cellulose, starch or sawdust also may be used.

Smokeless powder. SOC. ANON. ITALIANA DINAMITE NOBEL. Fr. 642,598, Oct. 19, 1927. A powder contains nitroglycerin 20-45, nitrocellulose 50-70, plastifier 2-10 and vaseline 2-6%. The plastifier may be diphenylurethan.

Flameless gun powder. N. I. DOVGELVICH. Russ. 5039, Sept. 15, 1924. Flameless powder is obtained by adding 3 to 10% of un-nitrated cellulose to the nitrocellulose during treatment in hollanders.

Apparatus for testing percussion caps. S. A. BROUNS. Russ. 3841, Oct. 31, 1927.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Classification of dyestuffs. CHAS. E. MULLIN. *Clemson College Textile School Textile Colorist* 50, 17-8(1928).—The classification of dyestuffs, including those for acetate silk, based upon their methods of application. CHAS. E. MULLIN

Dyeing in the seventeenth century. DAVID PATERSON. *Dyer, Calico Printer* 61, 8-9(1929). RUBY K. WORNER

Applying Indigosol O by the steaming process. CHAS. E. MULLIN. *Clemson College Textile School. Rayon J.* 2, No. 12, 15-6, 42(1927).—Methods and formulas are suggested. CHAS. E. MULLIN

Iron carbonyl in dyeing. H. POMERANZ. *Melliand Textilber.* 9, 843-4(1928). Iron carbonyl, $\text{Fe}(\text{CO})_5$, according to Ger. 441,179, is capable of reducing indigo and similar dyestuffs suspended in alk. soln. Mol. wts. indicate that 118 parts by wt. of Rongalit C is equal to 196 parts by wt. of $\text{Fe}(\text{CO})_5$. E. R. CLARK

The luminosity of dyeings. FRIEDRICH JACOBY. *Kaiser Wilhelm Institut für Physik. Chem., Berlin. Melliand Textilber.* 9, 837-40(1928).—Practical observation suffices to teach that with increasing time of dyeing or increasing concn. of dyestuff, a max. is reached beyond which the dyeing loses in brightness. Physically expressed, the effect is due to an approach to total absorption or blackness. With various methods of dyeing and with the aid of various dyeing assistants some variation in the shade corresponding to max. brightness is possible. Rational technological procedure should be based on the most economical production of lively, attractive shades. E. R. C.

Causes of unlevel dyeing on artificial silk. WM. BENNETT. *Silk J.* 5, No. 49, 66-7(1928).—A general discussion of the causes and suggested remedies. CHAS. E. MULLIN

The dyeing phenomena of acetate artificial silk. V. KARTASCHOFF AND G. FARINE. *Inst. chim. phys. Bâle. Helv. Chim. Acta* 11, 813-36(1928).—The soly. of several

anthraquinonic derivs. in abs. alc. has been detd.: 1-aminoanthraquinone, 3.51 g./l. at 60°; 1,4-diamino-, 5.54; 1,5-diamino-, 6.85; 1,8-diamino-, 6.82; 1,4,5,8-tetraamino-, 1.84; alizarin, 3.70; purpurin, 3.61; 1-hydroxy-4-amino-, 5.14; diaminoanthrarufin, 1.06; 1-methylamino-, 14.96; 1-amino-2-methyl-, 5.83; 1-amino-4-anilino-, 6.57; 1-amino-4-*p*-toluino-, 0.47; 1,4-di-*p*-toluino-, 0.34; 1,4-di-*p*-toluino-2-methyl-, 2.25. By using alc. solns. to dye the acetate silk, it is found that the partition coeff. is a const. The silk dyeing is thus a soly. phenomenon. There is an analogous mol. formation in the alc. and in the silk. In the dyeing with suspension of the dye in H₂O, pptn. on the surface of the fiber occurs first; solubilization in the fiber is a secondary process. The solubilities of the dyes in the silk have been detd. by color titration of the alc. soln. before and after dyeing. An NH₂ group favors the soly. of the silk. The 1,8-position is the most favorable. OH is a little more effective yet. CH₃ *para* to NH₂, or introduced into the NH₂ group itself, is favorable. Ph and MeC₆H₄ are unfavorable. The dyeing of acetate silk is explained as a soln. of the dye in the fiber. A. L. HENNE

Formulas and procedure for printing viscose rayon in the skein. RAYMOND CURTIS. *Textile World* 75, 493-5(1929). RUBY K. WORNER

Advances in textile chemistry. Recent German patents. ANON. *Wool Record* 33, 1639-41(1928).—A review. RUBY K. WORNER

Electrical conduction in textiles. I. E. J. MURPHY AND A. C. WALKER. Bell Tel. Lab., N. Y. *J. Phys. Chem.* 32, 1761-86(1928).—A study of the resistance of cotton, silk and wool samples with relative humidity and moisture content. The conductance of a cotton thread is equal to the sum of the conductances of the fibers of which it is composed; the rate of change of insulation resistance with relative humidity is independent of the form of the sample and of its electrolyte content. Equations are given for calcg. the resistance of a cotton sample for any moisture content. The rate of change of resistivity with moisture content is much greater for silk and wool than for cotton, and for a given moisture content the resistivity of silk or wool is greater than that of cotton. E. G. VAN DEN BOSCHE

A fiber comparator. S. G. BARKER AND M. C. MARSH. *Wool Record* 33, 1564-6, 1571(1928).—A comparator for fiber diams. is described and illustrated. It is a sample projection microscope with 2 sep. optical systems, giving adjacent images on the same screen of 2 sets of fibers, one being the sample and the other the standard. R. K. W.

Moisture content of textile fibers. W. G. SCHAFOSCHNIKOFF. *Melliand Textilber.* 9, 844-50(1928).—Samples of various types of cotton and of hemp, jute, wool, silk, linen and flax were weighed daily in Kiev for a period of 549 days. These tests showed that the international standards adopted in Turin in 1874 do not properly represent Russian conditions. Thus while 8.5% has been considered as the normal regain for cotton, the tests showed a min. of 6.87%, a max. of 15.28% and an av. of 11.66%. The av. regain of silk was 13.75%, of water-retted flax 14.15%, of hemp 14.72%, of jute 16.35%, of rayon 18.79%, of woolen 19.56% and of worsted 19.54%. The av. relative humidity was 76.8%. Hence the use of the Turin standards based on 65% relative humidity leads to transactions in terms of wts. which are quite erroneous in Kiev. It would seem that the maintenance of international standards of regain is impractical and that these should be replaced by standards suited to the given locality. E. R. CLARK

Absorption of colloidal solutions by fibers. W. HERBIG AND H. SEYFERTH. *Melliand Textilber.* 9, 921-4(1928).—The evaluation of wetting agents by measurement of the rise or spread of solns. in a supported or stretched thread gives data obviously contradictory to practical observation. So tested, soap solns. for example did not appear superior to plain H₂O. E. R. CLARK

Abacá-soil conditions in two districts of the Philippine Islands and their relation to fiber production. P. L. SHERMAN. *Philippine J. Sci.* 37, 1-19(1928); cf. following abstr. This study was made in 5 Bicol provinces and in Davao Province, thus furnishing examples of culture methods of 75 yrs. ago and those introduced within 2 or 3 yrs. Mech. and chem. analyses of 39 soil samples are tabulated, also the chem. analyses of ash of abacá fiber. The results of the continued cropping of the past are an exhaustion of plant-food minerals, a permanent acid condition, and a lack of essential mineral salts on which the plant depends for growth and resistance to disease. In the long-cultivated districts the yield is low, the fiber contains an excess of acidity and is low in tensile strength. The benefits of modern practice of abacá production in the Davao district are shown in increased yield and a uniformly high quality of fiber. L. W. RIGGS

Tensile strength of abacá fibers in relation to their acidity. P. L. SHERMAN AND HARTLEY EMBREY SHERMAN. *Philippine J. Sci.* 37, 21-40(1928); cf. preceding and

following abstr.—As the tensile strengths of abacá samples decrease about 10 kg. per g. of wt. per m. of length, the natural acidity of the fiber increases about 0.42 cc. (0.1 *N* NaOH, phenolphthalein indicator) for each 10 g. The natural acid content is also higher for Canton fibers with a low tensile strength, but the mathematical relationship between tensile strength and the acid content is less definite for these hybrids than it is for true abacá. Loss of tensile strength in abacá during storage is affected by the acid content, but the mathematical relation between loss of tensile strength and acid content so far has not been discovered. L. W. RIGGS

Fermentation as affecting the quality of Philippine abacá. TRINIDAD BANUELOS AND P. L. SHERMAN. *Philippine J. Sci.* 37, 41–65(1928); cf. preceding abstr.—In the Philippines some 85% of the semi-annual plant growth is cut down in the harvesting of the fiber and is allowed to ferment and decay underneath the growing immature plants. Accordingly the growing plant is infested with a large diversified bacterial flora. The process of drying, which should immediately follow the stripping of the fiber, sterilizes the fiber so long as it remains dry. Failure to dry the fresh fiber promptly and thoroughly, or wetting after once drier, results in fermentation, the immediate effects of which are the production of increased acidity, lowering of tensile strength, change of color and all of the phenomena that characterize damaged and perished fiber. These damaging effects on the fiber appear to be caused by the acid fermentation products of its sol. constituents, as well as by direct action of the bacteria on the fiber. L. W. RIGGS

Foreign matter in fabric and its effects on finishing operations. C. MARTINI, JR. *Melliand Textilber.* 9, 745–8(1928).—A collection of photographs showing the damage caused by metallic particles, pins, etc., present in fabric becoming embedded in calender rolls. E. R. CLARK

Cloth milling with acids. ALEXANDER YEWDALL. *Wool Record* 33, 830–3, 892–5, 955–7, 1018–21(1928).—General characteristics of the process, prepn. of solns., effects of stronger concns. and milled worsteds are considered. RUBY K. WORNER

What constitutes good fulling practice? A. W. DAVISON. *Textile Recorder* 46, No. 547, 67(1928).—See *C. A.* 22, 2468. RUBY K. WORNER

In mercerization, practice has kept ahead of the knowledge of principles. JOHN H. SKINKLE. Lowell Textile Inst. *Textile World* 75, 371–3(1929).—A brief survey of the theory of mercerization is given. RUBY K. WORNER

Measuring whiteness. ERHARD ZIEGER. *Melliand Textilber.* 9, 916–21(1928). Detrs. of the whiteness of cloth by use of the Ostwald half-shadow photometer gave results which varied with the nature of the illumination, the position of the sample, and particularly with the character of the fabric surface as this is influenced by the fiber, the weave and the smoothing operations of finishing. The use of such a test in com. transactions seems impractical; yet carefully handled the photometer gives data for routine operation control which are superior to the results of visual examination and comparison with fixed standards. E. R. CLARK

Warp sizing. PAUL SEYDEL. *Cotton* 90, 759–60; *Chem. Zentr.* 1927, II, 1399–S. describes the production, properties and chem. compn. of the weighting materials and other chemicals used for sizing the warp, as china clay, talcum, BaSO₄, CaSO₄, BaCl₂, MgSO₄, Na₂SiO₃, Na₂SO₄, glucose, dextrans and starch solns. G. S.

Four most likely causes for the shedding of size from warp yarn. GEOFFREY E. GOVIER. *Textile World* 75, 364–6(1929).—The chief cause is improper cooking of the starch. Other causes are the prepn. of too viscous or heavy a size, the excessive use of fatty matter, and the maintenance of too low a temp. in the size box. R. K. W.

Testing of cloth for wear resistance. H. MALDWIN WILLIAMS. *Wool Record* 34, 105–7(1928).—Various machines designed for this test are described. With the possible exception of one recently devised by Morton and Turner, none of these gives a practical measure. RUBY K. WORNER

Electrolytic bleach liquor for artificial silk. WM. BENNETT. *Silk J.* 4, No. 48, 60–1(1928).—General. CHAS. E. MULLIN

The progress of rayon. JANICE REED. *Wool Record* 34, 363–7, 379–83(1928). RUBY K. WORNER

Differences among commercial cottons and some suggestions regarding test methods. H. FIKENTSCHER. *Melliand Textilber.* 8, 521–4, 606–8, 685–8, 777–80, 855–8, 933–5(1927); 9, 129–31, 389–92, 479–82, 506–7(1928).—The results of phys. tests of 48 samples of cotton of different geographical origin are given. For technological purposes, cotton should be graded on color, purity, staple length, fineness, breaking length, roughness and extensibility. Each might be expressed numerically and a number arrived at which concisely represents the quality. Thus the number 2,136,548 would indicate cotton which rated No. 2 in color, No. 1 in purity, etc. E. R. C.

Some characteristics of wool as affecting worsted spinning. S. G. BARKER AND R. BURGESS. *Wool Record* 33, 823-9, 883-91, 951-3(1928). RUBY K. WORNER

Oils for wool. CHAS. E. MULLIN. Clemson College Textile School. *Textile Colorist* 50, 591-6(1928).—Where the oil must subsequently be removed by an aq. scouring bath, only mineral oils suitably blended with fatty oils, emulsifiers, etc., should be used. Emulsifying bases, the prepn. of wool oil emulsions and p_H control of the same, the "scourability" of wool oils, and p_H control in scouring are considered. C. E. M.

Effect of chemical and physical treatments on the hygroscopicity of wool. L. G. LEITES. *Melliands Textilber.* 9, 835-6(1928).—In connection with the operation of dryers for wool it is necessary to note that excessive temp. causes a permanent reduction in the affinity of wool for atm. moisture. Lab. tests with an oven operated at 10° intervals showed that the permanent change takes place at about 180° in 1 hr. of heating. This limiting temp. may be greatly reduced by the presence of residual chemicals. Cloth dried out of dil. Na_2CO_3 , H_2SO_4 and $K_2Cr_2O_7$ shows a permanent reduction in hygroscopicity. The mech. treatments given wool in the course of mfg. yarns and fabrics all tend to decrease its hygroscopicity, and the effects are permanent as was shown by weighings of the samples at regular intervals over a period of 1 year. The estn. of the H_2O absorption of wool in a definite atmosphere is suggested as a means of detecting undesirable effects of mfg. operations. E. R. CLARK

Solvents used for removing foreign matter in woollen pieces. KENNETH E. MARSDEN. *Textile Recorder* 46, No. 546, 66(1928).—A list of solvents is given for the removal of such impurities as spinning oils used in the mfg. process and loose dirt. Suggestions are also given for the removal of Fe, alum and white paint stains. RUBY K. WORNER

The spontaneous ignition of benzine. S. R. TROTMAN. *Textile Recorder* 46, No. 547, 65(1928).—In the dry-cleaning industry, conditions which favor ignition of the benzine are absence of moisture, presence of air, presence of hydrocarbons with a low flash point, and friction between the garment and solvent, or in the case of materials contg. 2 different fibers, friction between the adjacent threads. All the vessels used should be made of metal and be grounded. All sudden movements of the garments when not completely immersed in the solvent must be avoided. R. K. W.

Colour Lakes. Imperial Chemical Industries, Ltd. British Dyestuffs Corp., Ltd. Glasgow: British Dyestuffs Corporation, Ltd. 75 pp.

Dyes. FELICE BENSA. Fr. 640,959, Sept. 14, 1927. Perylene-3,9-dinitrile is heated with concd. H_2SO_4 , whereby a product contg. S and N is obtained, whose aq. or slightly acid soln. dyes wool and silk directly in yellow shades.

Dyes. D. GARDNER. Brit. 291,827, Feb. 5, 1927. Water-sol. products suitable for direct dyeing are obtained by treating dyes with anhydrous tetrachlorides or tetrabromides of metals of the fourth group of the periodic classification, with the use if necessary of an anhydrous org. solvent such as glacial HOAc. The process is applicable to insol. dyes such as "Indanthrene" vat dyes, indigoid dyes and aniline black and may also be applied to "more or less sol." dyes such as rhodamines and purpurin. Examples are given of the use of SnCl_4 and TiCl_4 .

Dyes. BRITISH DYESTUFFS CORP., LTD., ARNOLD SHEPARDSON and SYDNEY THORNLEY. Fr. 641,251, Aug. 23, 1927. Vat dyes are prep'd. by condensing a sulfo-benzanthrone with NH_4OH followed by alkali fusion. The products dye cotton from the vat in shades going from bluish violet to gray-blue or black. Examples are given using benzanthrone sulfonated with H_2SO_4 of 60° Bé. and with oleum, and 3-chloro-benzanthrone sulfonated with oleum as starting materials.

Dyes. J. R. GEIGY A.-G. Swiss 127,529, July 8, 1927. A monoazo dye is prep'd. by coupling the diazo comp'd. of 1-amino-2-sulfo-4-chlorobenzene-5-carboxylic acid with β -naphthol. The dye is a light red powder giving an orange color in water and a magenta color in concd. H_2SO_4 .

Dyes. E. I. DU PONT DE NEMOURS & Co. Ger. 469,179, Mar. 18, 1926. Dye comp'ds. sol. in org. solvents are prep'd. by converting a dye contg. the carboxyl or sulfo group into salts of di- or polyaryl- or aralkylguanidine. Thus, Pontamine yellow CH is dissolved in water and treated with dixylylguanidineacetate. The dye is ppt'd. It is readily sol. in $(\text{CH}_3)_2\text{CO}$, MeOH and AcOEt. It gives a fast blue color. Other examples are given.

Dyes. I. G. FARBERIND. A.-G. Brit. 291,546, March 14, 1927. The product obtained by alk. fusion of 1,2,1',2'-dinaphthazine-8,8'-disulfonic acid (which is regarded as 8,8'-dihydroxy-1,2,1',2'-dinaphthazine) is converted into halogenated products contg. more than 4 halogen atoms in the mol. by vigorous halogenation. The acyl derivs., or the lower halogenated products obtained by the process described in Brit. 241,270 (C. A. 20, 3576) may also be used as starting materials. The halogenation may be carried out in a diluent such as Ac_2O , a halogenated fatty acid, PhNO_2 , a halogenated hydrocarbon or a mixt. of diluents; a halogenation catalyst such as I also may be added. The products are converted into vat dyes, with partial removal of the halogen, by treatment with agents capable of splitting off halogen hydride such as concd. H_2SO_4 , inorg. or org. bases, NaOAc and the like, or by treating with reducing agents such as metals, SO_2 and its salts, hyposulfites, alcs., phenols, hydrazine and hydroxylamine. The final products in all cases contain more than 4 atoms of halogen in the mol. and dye vegetable and animal fibers from the vat in red shades, with a bluish or yellowish tinge depending on the temp. of the vat. By treatment with H_2SO_4 , or with org. solvents, the products may in some cases be sep'd. into dyes dyeing with a bluish tinge and those dyeing with a reddish tinge. Several examples are given.

Dyes. I. G. FARBERIND. A.-G. Brit. 291,552, March 18, 1927. *N* Dihydro 1,2,1',2'-anthraquinoneazine is chlorinated in H_2SO_4 of 85-95% strength, preferably with warming (suitably to 50°) and in the presence of a catalyst. The product is stated to be faster to Cl than that obtained by chlorinating in the presence of 96% H_2SO_4 .

Dyes. I. G. FARBERIND. A.-G. Brit. 291,851, March 7, 1927. The 9,10 disulfuric acid esters (or their salts) of anthrahydroquinones having an amino group (mono-substituted or not) in β -position and a free α -position ortho to the amino group are converted into vat dyes by the action of oxidizing agents while heated in a slightly acid soln. Examples are given of the manuf. of several dyes which give various blue shades on cotton from the vat. Details are also given of the production of the starting materials for the dye manuf.

Dyes. I. G. FARBERIND. A.-G. Brit. 291,878, March 10, 1927. 1-Aminoanthraquinone-2-aldehyde is condensed with a 1-haloanthraquinone (or a deriv. or substitution product) in the presence of an acid-binding agent such as NaOAc and a catalyst facilitating the elimination of halogen hydride such as Cu or a Cu salt. The dianthraquinonylamine-2-aldehydes thus formed yield condensation products with aniline and by treatment with acids or alkalies are converted into dianthraquinone-acridines, which dye cotton from the vat. Examples are given of dyes which give yellow-brown and dark blue-violet dyeings.

Dyes. I. G. FARBERIND. A.-G. Brit. 291,887, March 11, 1927. Triarylmethane dyes are obtained by condensing 2 mols. of an aromatic *o*-hydroxycarboxylic acid with 1 mol. of 4-benzylamino-3-sulfobenzaldehyde or one of its salts and oxidizing the resulting leuco compd. By using *o*-cresotic acid and 4-benzylamino-3-sulfobenzaldehyde as starting materials, a dye is obtained which dyes wool violet.

Dyes. I. G. FARBERIND. A.-G. Brit. 291,888, March 11, 1927. Dyes giving orange-red to yellow shades are obtained by condensing a 1,3,3-trialkyl-2-methyleneindoline base or substitution product with an ester or salt of nitrous acid in the presence of an acid anhydride such as Ac_2O which serves as a condensing agent. NaNO_2 or AmNO_2 may be used.

Dyes. I. G. FARBERIND. A.-G. Fr. 640,939, Aug. 30, 1927. Vat dyes are prepd. by condensing *N*-benzanthranylpyrazoleanthrones with alk. condensing agents. Other dyes may be prepd. by halogenating the condensation products, or by nitrating and reducing, or by oxidizing and alkylating. In examples, the benzanthranylpyrazoleanthrone obtained by treating pyrazoleanthrone with *Bz*-1-bromobenzanthrone in the presence of K_2CO_3 is condensed with KOH , giving a product which dyes cotton pure blue from the vat. If a higher temp. is used a different product is obtained which dyes cotton grayish green to black. *Bz*-2-Phenylbenzanthranylpyrazoleanthrone gives a product which dyes cotton green. *N*-*Bz*-1-Benzanthranyl-4-methylpyrazoleanthrone (from 4-methylpyrazoleanthrone and *Bz*-1-bromobenzanthrone) when condensed gives a greenish blue on cotton. *N,N'*-Dibenzanthrondipyrazoleanthrone (from 1 mol. of dipyrazoleanthrone and 2 mol. of *Bz*-1-bromobenzanthrone) when condensed gives a reddish blue. Several other examples are given.

Dyes. I. G. FARBERIND. A.-G. Fr. 641,816, Oct. 4, 1927. Azo dyes are obtained by combining aromatic diazo compds. with 2,6-naphtholcarboxylic acid. In an example PhNH_2 is diazotized and the soln. run into an aq. soln. of Na 2,6-naphtholcarboxylate with the addn. of the necessary amt. of NaOAc to neutralize the free mineral acid. The dye colors wool in yellowish red shades. Similar shades are obtained with the dye from *p*-chloroaniline-*o*-sulfonic acid, and brown shades are obtained with the dye from *p*-nitro-*o*-aminophenol. A further list of components and colors obtained is given.

Dyes. I. G. FARBERIND. A.-G. Fr. 641,716, Oct. 1, 1927. Vat dyes are prepd. by treating benzanthrone compds. contg. one or more arylsulfonamido groups with alk. condensing agents. If compds. contg. one or more arylsulfonamido groups in positions other than the 2- and *Bz*-1 positions are used, the condensation products are treated with saponif. agents to sep. the arylsulfonyl radical from the arylsulfonamido group in these positions. In examples: *Bz*-1-(*p*-tolylsulfonamido)benzanthrone (by treating *Bz*-1-benzanthrone with *p*-toluenesulfonyl chloride, or by condensing *Bz*-1-halobenzanthrone with *p*-toluenesulfonamide) is condensed with KOH in alc. giving a product which dyes cotton reddish blue from the vat. 6-Phenylsulfonamido-*Bz*-1-bromobenzanthrone (by nitrating *Bz*-1-bromobenzanthrone, reducing and treating with benzenesulfonyl chloride) is condensed and the phenylsulfonyl radical removed from the phenylsulfamido- in the 6-position by H_2SO_4 ; the product dyes cotton in grayish blue shades of excellent fastness. 6-*Bz*-1-Bis(phenylsulfonamido)benzanthrone prepd. as above is condensed and saponif. as above, giving a product which dyes cotton in gray to black shades.

Dyes. I. G. FARBERIND. A.-G. Fr. 641,769, Oct. 3, 1927. New *o*-hydroxyazo dyes are prepd. by combining aromatic *o*-hydroxydiazo compds. with 2,8-dihydroxynaphthalene-6-carboxylic acid, preferably in alk. soln. In examples: 4-chloro-2-aminophenol is diazotized and coupled with the above acid, the dye giving uniform brown shades on cotton. Chroming gives black shades. With 4-nitro-2-aminophenol, a dye is obtained giving brownish red shades on cotton, turning to brown after chroming. Other examples are given.

Dyes. I. G. FARBERIND. A.-G. Fr. 641,832, Oct. 5, 1927. Dinitroarylamino-diarylamine dyes are obtained by condensing *p*-aminodiphenylamine, its homologs or its substitution products with 4-halo-1,3-dinitro-6-*X*-benzene or 4-halo-3,5-dinitro-1-*X*-benzene, where *X* may be $-\text{COOH}$, $-\text{COO}$ metal, $-\text{COO}$ alkyl, $-\text{CON}$ -arylalkyl,

$-\text{SO}_2\text{N}$ arylalkyl or $-\text{SO}_2\text{O}$ aryl. The products dye animal fibers yellow to brown-red shades and give fast dyes on cellulose esters or ethers. In examples, 4-aminodiphenylamine 4-methyl-2-sulfonic acid is heated in water contg. chalk with 4-chloro-3,5-dinitro 1 (SO_2N -PhMe)-benzene. 4-Aminodiphenylamine-2-sulfonic acid is heated

with 4-chloro-3,5-dinitro-1-benzoic acid. *p*-Aminodiphenylamine is heated with 4-chloro-3,5-dinitro-1-benzoic acid.

Dyes. I. G. FARBENIND. A.-G. Fr. 642,127, Oct. 8, 1927. Vat dyes of the dipyrazoleanthrone series are obtained by heating dipyrazoleanthrone obtained as in Fr. 451,093, or its substitution products, contg. at least 1 atom of H attached to the N capable of being substituted, with aromatic or aliphatic aldehydes in the presence of chlorides of P, Sb or Al, with or without diluents. In examples, dipyrazoleanthrone is suspended in BzH and PCl_3 is added. The mass is heated to 130–140°. The product dyes cotton a clear yellow from the vat after exposure to the air. Dichloropyrazoleanthrone (see Fr. 599,479) is suspended in PhNO_2 , BzH and SbCl_5 are added and the mixt. is heated as before. The product dyes cotton brownish yellow shades. Tetra-bromodipyrazoleanthrone (see Fr. 599,479) is heated in BzH in the same way, giving a product which dyes cotton an orange shade. Other examples are given.

Dyes. I. G. FARBENIND. A.-G. Fr. 642,206, Oct. 12, 1927. New azo dyes are prepd. by coupling diazo compds. of 2-aminobenzene-1-carboxylic-sulfonamides or their derivs. or substitution products with any components and the products are treated in substance or on the fiber with substances yielding metals. In examples, 2-aminobenzene-1-carboxy-5-sulfo-2'-anisidide is diazotized and coupled with 1-naphthol 5 sulfonic acid. The product dyes wool orange-yellow in an acid bath. By chroming the color changes to Bordeaux. 2-Aminobenzene-1-carboxy-5-sulfonanilide is diazotized and coupled with the pyrazolone and 2-amino-1-phenol-4-sulfo-6-carboxylic acid. A reddish yellow is obtained on wool, which is changed to a greenish yellow by chroming. Other examples are given.

Dyes. I. G. FARBENIND. A.-G. Fr. 642,248, Oct. 13, 1927. Azo dyes are obtained by combining the arylides of 2-arylamino-8-naphthol-6-carboxylic acid with a diazo compd. In examples, cotton is impregnated with the anilide of 2-phenylamino-8-naphthol-6-carboxylic acid in the usual way and the color is developed in a soln. contg. diazotized 3-chloroaniline. An olive shade of good fastness is obtained. A tetraazo soln. of dianisidide is combined with a soln. of the β -naphthalide of 2-phenylamino-8-naphthol-6-carboxylic acid in dil. NaOH contg. NaOAc to neutralize the mineral acid. With the usual substrata a black lake of excellent fastness is obtained. Other examples are given.

Dyes. I. G. FARBENIND. A.-G. Fr. 642,351, Sept. 13, 1927. New vat dyes are obtained by treating with alk. agents the aminobenzanthrone (I) which is formed by reduction of the nitrobenzanthrone (II) prepd. according to Fr. 6,435,349,531 or its derivs. contg. substituents in the *Bz*-1 position capable of being exchanged or their *N*-acylated derivs. The crude dye may be subsequently treated with oxidizing agents, or the nitro compd. may be used instead of the amino compd. In examples I is heated with KOH-EtOH; the product dyes cotton in full green shades. If the product is oxidized with chromic acid it dyes cotton brown shades. If molten KOH is used instead of KOH-EtOH a gray color is obtained on cotton. Amino-*Bz*-1-bromobenzanthrone (III) (by brominating the acetyl deriv. of I and sapon.) is heated with KOH-EtOH; the product dyes cotton green which turns brown by chloring. Examples are also given, using acetylaminobenzanthrone-*Bz*-1-thiocresylic ether (by condensing III with *p*-thiocresol), the Me ether of amino-*Bz*-1-benzanthronemercaptan (by methylation of the Na compd. of amino-*Bz*-1-benzanthrone (IV) formed as a by-product in the reduction of (II) with Na_2S), and diacetyl-amino-*Bz*-1,*Bz*-1'-dibenzanthronylic sulfide (by condensing the acetyl deriv. of IV with the acetyl deriv. of III).

Dyes. I. G. FARBENIND. A.-G. Fr. 642,501, Oct. 17, 1927. Cellulose esters and ethers are dyed brown by dyes not contg. free sulfo groups obtained by condensing *p*-aminodiphenylamine or its homologs or substitution products with 1,2,4,6- $\text{ClC}_6\text{H}_2\text{X}_2$, where 2 of the X symbols represent nitro groups and the 3rd is any substituent, the dye contg. at least one carboxyl group. Examples of dyeing with these compds. are given.

Dyes. I. G. FARBENIND. A.-G. (Kurt H. Meyer, Heinrich Hopff and Arthur Krause, inventors). Ger. 469,019, Aug. 28, 1925. Addn. to Ger. 436,536. A further development of the method of prepn. of vat dyes of the anthraquinone series consists in condensing with aminoanthraquinone or its derivs., *m*-substituted derivs. of benzoic acid, including the carboxylic acid, halide and anhydride. Thus diaminoanthraquinone, nitrobenzene and *m*-toluyl chloride are heated, giving a dark violet vat which dyes cotton a fast bluish red color. Isophthalic acid, α -aminoanthraquinone and trichlorobenzene are heated and thionyl chloride is added at 70–80°, giving a cherry-red vat, which dyes cotton a fast greenish yellow. A table of dye constituents with the corresponding vat, and cotton colors is given.

Dyes. I. G. FARBENIND. A.-G. (Karl Schirmacher and Hans Neumann, inventors).

Ger. 469,178, Oct. 22, 1926. Benzocoumaranone is condensed with a 2-deriv. of isatin, 2,3-diketodihydronaphthene, coumaranone, penthiophene, or an *o*-diketone; or a 2-deriv. of benzocoumaranone is treated with indoxyl, oxythionaphthene, coumaranone, penthiophene or methylene compds. having a removable H atom in the methylene group. Thus, benzocoumaranone dissolved in pyridine, glacial AcOH, or PhNO_2 , with isatinanilide, produces a dye which appears as copper-red crystals of m. p. 350° . It colors animal and vegetable fibers a red-violet tone. Another example is given.

Dyes. I. G. FARBENIND. A.-G. (Richard Stüsser, inventor). Ger. 469,341, Apr. 22, 1927. Disazo dyes are prep'd. by coupling the urea or thiourea substitution compds. contg. aminoaroyl-2,5-diaminobenzoic acid groups with azo compds. The substitution compd. may have one or more similar or different aminoaroyl groups. Thus, nitroanthranilic acid is diazotized and coupled with 1-*p*-mercaptophenyl-3-methyl-5-pyrazolone. The nitroazo dye resulting is then reduced to the aminoazo dye and condensed with $m\text{-O}_2\text{NC}_6\text{H}_4\text{COCl}$ until no free amino group is left. The filtered *m*-nitrobenzoyl-aminoazo dye is then treated with Na_2S to obtain the *m*-aminobenzoylaminoazo dye. This is converted to the urea compd. in the usual way with AcONa . The dye is a yellow-brown powder, coloring unmordanted cotton light and washing-fast yellow. Other examples are given.

Dyes. I. G. FARBENIND. A. G. (Wilhelm Bauer, Wilhelm Neelmeier and Theodor Nocken, inventors.) Ger. 469,343, June 12, 1926. An indigoid dye is prep'd. by condensing the reactive α -deriv. of 2,3-naphthisatin which has been halogenated in the nucleus, with the ethers of 1,4-naphthalenediol or derivs. in which there is no substitution of the hydroxyl group in the *o*-position. Thus, bromo-1-chloro-2,3-naphthisatin is coupled with 4-methoxy-1-naphthol in a soln. of chlorobenzene. The dye so formed gives a fast green color to textile fabrics.

Dyes. I. G. FARBENIND. A.-G. Swiss 127,525, Mar. 15, 1927. A mordant disazo dye is prep'd. by sulfonating the benzene-1,4-disazosalicyclic acid obtained by the action of the diazo compd. on *p*-aminobenzencazosalicyclic acid. A sulfo group is introduced into the *o*-position of both salicylic acid radicals in the dye mol. The dye is salted out from alk. soln. as a red-brown powder which, in water, is orange-red, and in H_2SO_4 red-violet.

Dyes. I. G. FARBENIND. A.-G. Swiss 127,526, Apr. 21, 1927. A black azo dye is prep'd. by coupling diazotized diethylphenosafranin with *p*-cresol.

Dyes. I. G. FARBENIND. A.-G. Swiss 127,527, May 4, 1927. An azo dye is prep'd. by coupling the diazo compd. of 2,4,6-trinitro-1-aminobenzene with *N*-ethyl- λ -1'-sulfobenzyl-*m*-toluidine. The dye is a reddish blue in water, and blue-black in acid baths.

Dyes. I. G. FARBENIND. A. G. Swiss 127,528, July 8, 1927. An azo dye is prep'd. by coupling the diazo compd. of 1,3-dimethyl-4-amino-6-chlorobenzene with 2-hydroxynaphthalene-3-carboxylic acid 4'-chloro-2'-methylanilide. The dye is a red powder giving in alk. baths a clear red color, fast to light.

Dyes. I. G. FARBENIND. A.-G. Swiss 127,532, Apr. 1, 1927. An indigoid dye is prep'd. by halogenating 8-chloro-1,2-naphthisatin in the α -position, and acting upon the product with 4-methyl-6-chloro-3-hydroxythionaphthene. The dye is dark violet and gives a green color in concd. H_2SO_4 . It dyes cotton from an orange-yellow vat with a violet tone which is fast to light, water and Cl.

Dyes. I. G. FARBENIND. A.-G. Swiss 127,533, May 4, 1927. A vat dye is prep'd. by brominating 7-methyl-2,2-indolethionaphtheneindigo in H_2SO_4 till two atoms of Br are taken up. The dibromo-7-methyl-2,2-indolethionaphtheneindigo gives a fast violet color.

Dyes. I. G. FARBENIND. A.-G. Swiss 127,704, May 7, 1927. Addn. to Swiss 117,356. A stable diazo compd., $\text{Cl}(\text{MeO})\text{C}_6\text{H}_3\text{N}_2\text{Cl}$, is prep'd. by treating 4-chloro-2-aminoanisole with a Zn compd. It reacts readily with coupling components to form dyes.

Dyes. SOC. ANON. POUR L'IND. CHIM. A BALE. Brit. 291,768, June 8, 1927. Derivs. of vat dyes are obtained by treating their leuco compds. such as leucothioindigo or indigo white with org. acids such as chloroacetic acid, contg. an exchangeable halogen atom. β -Chloropropionic acid and sulfobenzyl chloride also may be used. The products may be used for printing and may be developed with oxidizing agents. Several examples are given.

Dyes. SOC. ANON. POUR L'IND. CHIM. A BALE. Brit. 290,179, May 7, 1927. Dyes which give dyeings on cotton, from a Na sulfide bath, that are fast to washing and to light are obtained by the action of sulfurizing agents on Cr compds. of various azo dyes. Dyes of various bluish shades are thus obtained and among the dyes which may be

used as starting substances are the monoazo dye from 1-naphthol and 1,2-aminonaphthol-4-sulfonic acid and the monoazo dye from 5,8-dichloro-1-naphthol and 1,2-aminonaphthol-4-sulfonic acid.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Ger. 467,349, Mar. 12, 1925. Metallic compds. of *o*-hydroxymonoazo dyes are prepd. from 1,8-naphthosultone either by sulfonation, nitrication, splitting the sultone rings by adding ammonia, and reducing, or by sulfonation, splitting the sultone rings by adding ammonia, nitrication, and reducing. The 1-hydroxynaphthalene-8-sulfamido-2-amino-4-sulfonic acid so produced is diazotized, united with developing components, and the hydroxyazo dye resulting is treated with suitable metallic compds., such as those of Cu and Cr. A table of developing components and corresponding dye colors is given.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 127,715. Addn. to Swiss 119,986. Brominated violanthrone contg. about 30% Br is treated with a chlorinating agent immiscible with water, at 80°. The substance obtained is a mixt. of the tetra- and pentachloro derivs. and only contains a trace of Br. It dyes cotton blue, fast to water.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 636,970, July 4, 1927. New azo dyes are prepd. having the general formula $R^1-N=N-R^2-NH-C(:X)-NH(R^3)$, in which R represents an α -naphthol residue coupled in the *peri*-position to the azo group, R² an aromatic ring coupled in the 4-position to the amino group, X an atom of O or of S, R³ a complex group contg. at least 2 aromatic rings united by an azo group, by combining by means of COCl₂ or its substitutes or CSCI₂ or CS₂, two mols. of aromatic amino compds. of which at least one is an aminoazo dye obtainable by coupling a diazotized 1,8-aminonaphthol (of which the OH group may be acylated) with a primary amine of the benzene or naphthalene series, while the other is any ammono- or polyazo dye or a component of such a dye which can be transformed into the dyestuff after being united with the first-mentioned aminoazo dye. The products dye vegetable fibers in various shades of orange, red and blue, fast to light. The fastness in some cases may be increased by after-treatment with metal salts, or the dyes may be converted into metal compds. In an example the monoazo dye obtained by coupling the *p*-toluenesulfonate of 1,8-aminonaphthol-3,6-disulfonic acid with cresidine is treated with COCl₂ and the product obtained by salting out is treated with NaOH soln. to remove the acyl group. It dyes cotton in blue-red tints. Several other examples are given.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 641,675, Sept. 30, 1927. Amino azo dyes obtained by coupling non-sulfonated diazo compds. contg. a nitro group *o*- to the diazo group with primary, secondary or tertiary amines, are used for dyeing cellulose derivs., e. g., acetate silk. In examples, diazotized *o*-nitroaniline is added to Na aniline-*o*-methanesulfonate and NaOAc. The sulfonic group is saponified and the dye pptd. Diazotized *o*-nitroaniline is coupled with PhNMe₂. The nitroamine may be replaced by 4-chloro-2-nitroaniline, *m*-nitro-*p*-toluidine, etc., and these may be coupled with PhNEt₂, *o*-toluidine, *o*-anisidine, *p*-xylydine, etc.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 642,578, Oct. 19, 1927. New vat dyes are prepd. by sulfonating violanthrone and isoviolanthrone dyes, fusing with caustic alkalis and treating with etherifying agents or with halogenating agents followed or not by etherification. Similar dyes are obtained by sulfonating benzanthrone, fusing with alkalis and etherifying. In examples violanthrone is sulfonated with oleum; the product dyes cotton blue from the vat. If this dye is fused with KOH a product is obtained which dyes cotton gray tinged with blue, and methylation gives a product which dyes cotton bluish gray fast to Cl. Halogenation with SO₂Cl₂ instead of methylation gives a product which dyes cotton slightly bluer. Other examples are given.

Azo dyes. ERWIN HAFFA, ERWIN THOMA and HANS HRYNA (to Grasselli Dyestuff Corp.). U. S. 1,698,884, Jan. 15. By coupling a 2,5-dimethyl-4-halo-1-diazo-benzene in which one of the H atoms standing in the 3 and the 6 positions is replaced by a further halogen with an arylamide of 2-hydroxynaphthalene-3-carboxylic acid, azo dyes are obtained which are of especially good fastness to kier-boiling. Examples are given of dyes producing various red shades. Cf. C. A. 23, 990.

Azo dyes. HERMANN WAGNER and OTTO SOHST (to Grasselli Dyestuff Corp.). U. S. 1,698,898, Jan. 15. 4-Benzenesulfomethylamino-2-amino-1-methoxybenzene or a similar aromatic amine (such as may be produced by causing an aryl sulfonyl chloride to react upon a 4-amino-2-nitro-1-alkoxybenzene and subsequently alkylating or benzylating and reducing) is diazotized and coupled with a 2-hydroxynaphthalene-3-car-

boxylic acid arylamide. Numerous examples are given, for the production of dyes giving various shades of red.

Azo dye. I. G. FARBENIND. A.-G. Swiss 127,261, Feb. 14, 1927. An azo dye is prep'd. by coupling diazotized 4,6-dinitro-2-amino-1-hydroxybenzene with 1-amino-8-hydroxynaphthalene in the presence of an acid-binding agent. The product is sol. in water and is useful in the direct dyeing of ethers and esters of cellulose or its conversion products. Acetate silk, for instance, is dyed in black shades, which are deepened if the dye is diazotized on the fiber and developed with 2,4-tolylene-diamine.

Azo dyes. I. G. FARBENIND. A.-G. Swiss 127,441-127,444, May 10, 1926. Addns. to 123,737. Azo dyes are prep'd. by treating the following compds. with salicylic acid sulfonyl chloride: (1) 1,1'-azobenzene-3,4'-disulfoazo-2-methylamino-5-naphthol-7-sulfonic acid (127,441), (2) 1,1'-azobenzene-3,4'-disulfoazo-2-methylamino-8-naphthol-6-sulfonic acid (127,442), (3) 2',5'-dimethyl-1,1'-azobenzene-2,5-disulfoazo-2-methylamino-5-naphthol-7-sulfonic acid (127,443), and (4) 2',5'-dimethyl-1,1'-azobenzene-2-sulfoazo-1-ethylamino-8-naphthol-3,6-disulfonic acid (127,444).

Azo dye. I. G. FARBENIND. A.-G. Swiss 127,714, Apr. 27, 1927. Addn. to 126,200 (C. A. 23, 715). An azo dye is prep'd. by coupling diazotized *p*-aminoacetanilide with *p*-cresol and splitting off the Ac group from the product by heating with NaOH. The dye is suitable for cellulose esters and ethers.

Azo dyes. I. G. FARBENIND. A.-G. Fr. 637,131, July 6, 1927. Certain halogenated xylydines, particularly the 5-halo-2,4-xylydines and the 3,5-dihalo-2,4-xylydines when diazotized and coupled with an arylamide of 2-naphthol-3-carboxylic acid give dyes fast to Cl, light and boiling. Similar dyes are obtained if the 5-halogen is replaced by H or an alkyl group. Thus, yellow or red shades are obtained by coupling diazotized 5-chloro-2,4-xylydine with the 5-chloro-2-methoxyanilide of 2-naphthol-3-carboxylic acid or with the 4-chloro-2-methylanilide of 2-naphthol-3-carboxylic acid or with the *β*-naphthylamide. Examples are given. The dihalogen bases referred to are new and are prep'd. by halogenating 2,4-xylydine in H₂SO₄.

Azo dye. I. G. FARBENIND. A.-G. (Richard Stüsser, inventor). Ger. 469,340, Mar. 11, 1927. A disazo dye is prep'd. by coupling tetraazotized 4,4'-diaminodiphenyl-3,3'-dicarboxylic acid and its derivs. in any sequence with an aryl-naphthylaminesulfonic acid or one of its derivs., and such azo components as contain sulfo, carboxyl, hydroxyl or amino groups. Thus, 4,4'-diaminodiphenyl-3,3'-carboxylic acid is tetraazotized and coupled with 8-hydroxy-1-phenylaminonaphthalene-4-sulfonic acid. The dye so obtained colors cotton a blue fast to light and to washing. Other examples are given.

Azo dye. I. G. FARBENIND. A.-G. (Ernst Fellmer, inventor). Ger. 469,288, Oct. 15, 1925. A trisazo dye is prep'd. by combining an aminoazo substance derived from a nitro- or acyl-*p*-diamine or its derivs. and a further diazotized intermediate component, with an amino group-contg. deriv. of aminonaphtholsulfonic acid. The diazo dye so obtained is further diazotized and coupled with methylketol or methylphenylpyrazolone or its derivs. and the acyl group of the initial component split off, or the nitro group reduced. Thus 4-acetyl-amino-1-aminobenzene-2-sulfonic acid is diazotized, and 1,2-aminoethyl-naphtholate-6-sulfonic acid added. The product is diazotized and coupled with *p*-aminobenzoyl-2-amino-5-naphthol-7-sulfonic acid. The diazo dye is then diazotized and coupled with methylphenylpyrazolone. The acetyl group is split off by heating in a weak acid or alk. soln. and the trisazo dye isolated in the usual way. It gives a clear green color when used directly and when developed by *β*-naphthol. Other examples are given.

Azo dye. SOC. ANON. POUR L'IND. CHIM. A BALR. Swiss 127,259, Dec. 4, 1926. A yellow azo dye is prep'd. by coupling diazotized 4-acetamido-2-amino-1-benzene-sulfonic acid with 1-*p*-sulfophenyl-5-pyrazolone-3-carboxylic acid. On wool, the product gives effects like those of tartrazine.

Azo dye. SOC. ANON. POUR L'IND. CHIM. A BALR. Swiss 127,260, Dec. 24, 1926. A yellow azo dye is prep'd. by coupling diazotized 2-nitro-1-amino-4-methylbenzene with 3-methyl-5-pyrazolone. The product dyes acetate silk in yellow shades.

Disazo dyes. HEINRICH CLINGSTEIN and HARRY W. GRIMMEL (to Grasselli Dyestuff Corp.). U. S. 1,697,107, Jan. 1. A disazo dye which gives deep black dyeings is formed from 7-hydroxynaphthocarbazole and 2,7-diaminocarbazole. Other similar components produce brown, to violet, to blue, to black dyes.

***o*-Hydroxyazo dyes.** SOC. ANON. POUR L'IND. CHIM. A BALR. Ger. 468,483, Aug. 28, 1926. The aminoazo dyes formed by reduction of the coupling products from nitrated diazo compds. of 1-amino-2-naphthol-4-sulfonic acid and naphthols are treated with CH₂O and NaHSO₃ or with formaldehydesulfurous acid (sulfurous acid methylol ester) or its salts. An example is given. Cf. Brit. 258,854 (C. A. 21, 3133).

Polyazo dyes. RUDOLPH KRECH and ERICH KEINER (to Grasselli Dyestuff Corp.). U. S. 1,697,122, Jan. 1. A disazo dye which gives red dyeings is formed from 4,4'-diamino-3,3'-dichlorodiphenylmethane and Na 2-naphthol-4-sulfonate and similar dyes may also be produced from various similar starting materials.

Vat dyes. GEORG KALISCHER and RUDOLF MÜLLER (to Grasselli Dyestuff Corp.). U. S. 1,697,361, Jan. 1. Yellow to orange vat dyes are obtained by heating, to above 200° (suitably to about 240–250°) 2-methylantraquinone, S and a primary aromatic diamino compd. such as 1,5-naphthylenediamine or diaminobenzanthrone and purifying the products by the action of alk. oxidizing agents such as NaOCl. Cf. C. A. 23, 991.

Vat dye. I. G. FARBENIND. A.-G. Swiss 127,264, Jan. 13, 1927. A vat dye is prep'd. from the benzobenzanthronecarboxylic acid described in Swiss 126,194 (C. A. 23, 991) by treating it first with an alk. condensing agent and then with an acid condensing agent. The product gives violet-black vats with alk. Na₂S₂O₄ from which cotton is dyed in the same colors, changing to greenish blue on hanging or soaping.

Vat dye. I. G. FARBENIND. A.-G. Swiss 127,265, Feb. 24, 1927. A vat dye is prep'd. by heating 2-bromo-1,9-pyrazoleanthrone in the presence of an acid-binding agent and a metalliferous catalyst. The product dyes cotton blue in the vat, the color changing to red on hanging. 2-Bromo-1,9-pyrazoleanthrone may be prep'd. from 1-amino-2-bromanthraquinone by diazotizing and reducing to the hydrazine deriv., which undergoes internal condensation.

Vat dye. I. G. FARBENIND. A.-G. Swiss 127,268, Feb. 14, 1927. A vat dye is prep'd. by condensing 4,7-dimethyl-5-chlorohydroxythionaphthene with a 5,7-dichloroisatin having a labile substituent in the α -position. 4,7-Dimethyl-5-chlorohydroxythionaphthene may be prep'd. from 1-amino-4-chloro-2,5-xylene by conversion into 4-chloro-2,5-xylene-1-thioglycolic acid and effecting ring closure by known methods. Cf. Brit. 274,527 (C. A. 22, 2277) and 266,382 (C. A. 22, 689).

Vat dye. I. G. FARBENIND. A.-G. Swiss 127,448, Dec. 28, 1926. Addn. to 125,722. 1-Hydroxy-3,4-benzo-8,9-(γ -methyl)benzopyrone-5,10-quinone is prep'd. by treating the *p*-toluic acid ester of Bz-2-hydroxybenzanthrone with acid-condensing agents. The product is useful as a dye or dye intermediate. The *p*-toluic acid ester of Bz-2-hydroxybenzanthrone is prep'd. by heating Bz-2-hydroxybenzanthrone with an equal amt. of the acid chloride.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 33,005, Jan. 29, 1927. Addn. to 600,843. 1,4,5,8-Naphthalenetetracarboxylic dianhydride or the acid itself is condensed with *o*-nitroamino compds. or their salts in the presence or absence of a solvent or diluent and the product reduced to obtain the same dyes as obtained in Fr. 600,843. In examples 1,4,5,8-naphthalenetetracarboxylic acid is boiled with 3-nitro-4-aminophenetole in PhNO₂ and the product reduced. The dye gives brown-red shades on cotton from the vat. The formula is probably

A clear brown shade is obtained if the phenetole compd. is replaced by the anisole compd., and a brilliant red if *o*-nitroaniline is used.

Vat dye. I. G. FARBENIND. A.-G. (Hans Heyna, Carl J. Müller and Ernst Fischer, inventors). Ger. 469,342, Feb. 21, 1926. A dye of the 2-thionaphthene-2'-indole-indigo series is prep'd. from 3-hydroxy-1-thionaphthene which has substituted in the 4-, 6- and 7-positions, three halogen atoms, or two halogen atoms and an alkyl group, or one halogen atom and two alkyl groups, by condensing it with α -derivs. of isatin or its substitution products, homologs, or analogs. Thus, 5-chloro-*o*-toluidine-HCl is transformed into 4-methyl-6,7-dichloro-3-hydroxy-1-thionaphthene by 1-methyl-2-amino-4,5-dichlorophenyl-3-thioglycolic acid. By condensation of this hydroxy-thionaphthene with 5,7-dichloroisatin-2-chloride in chlorobenzene, the 4-methyl-6,7-

lichloro-2-thionaphthene-5',7'-dichloro-2'-indoleindigo is obtained. It colors cotton red-violet fast to light and washing.

Nitrogenous vat dyes. I. G. FARBENIND. A.-G. (Max Kunz and Karl Köberle, inventors). Ger. 468,577, Jan. 19, 1927. Vat dyes are prepd. by reaction between negatively substituted *ms*-naphthodianthrone or its derivs. and aminoanthraquinones having at least one unsubstituted H atom in the NH_2 group. The reaction is preferably conducted in presence of diluents; acid-binding substances may also be present. Examples describe the prepn. of dyes from tribromo-*ms*-naphthodianthrone (prepd. from tribromo-*ms*-benzodianthrone by heating with AlCl_3) and α -aminoanthraquinone; tetrabromo-*ms*-naphthodianthrone (prepd. from tetrabromo-*ms*-benzodianthrone by treatment with AlCl_3) α - and β -aminoanthraquinone; dichloro-*ms*-naphthodianthrone (prepd. by chlorinating *ms*-naphthodianthrone) and α -aminoanthraquinone; and bromo-2,2'-dimethyl-*ms*-naphthodianthrone (prepd. by brominating 2,2'-dimethyl-*ms*-naphthodianthrone) and 1-amino-4-methoxyanthraquinone, each reaction being effected in PhNO_2 soln. or suspension and in presence of AcONa and CuCO_3 . The product from tetrabromo-*ms*-naphthodianthrone and 1-amino-4-methoxyanthraquinone is mentioned also.

Vat dyes of the anthraquinone series. I. G. FARBENIND. A.-G. (Paul Nawiasky and Arthur Krause, inventors). Ger. 468,356, Nov. 23, 1926. Vat dyes of the anthraquinone series are prepd. by oxidizing the condensation products from 1-aminoanthraquinone or its derivs. and *Bz*-1-halobenzanthrones. An example describes the oxidation of *Bz*-1-halobenzanthronyl-1-aminoanthraquinone with MnO_2 and H_2SO_4 . The products prepd. by oxidizing (1) the condensation product from 1,5-diaminoanthraquinone and 2 mols. of *Bz*-1-bromobenzanthrone and (2) the condensation product from 1-benzoylamino-5-aminoanthraquinone and *Bz*-1-bromobenzanthrone are also mentioned.

Dyes and intermediates. I. G. FARBENIND. A.-G. Fr. 642,221, Oct. 13, 1927. Thio ethers of the anthraquinone series are prepd. by reaction of either any diazo compd. on anthraquinonemercaptans, their derivs. or substitution products, or diazo compds. of the anthraquinone series on any mercaptan. The reaction is of importance in the prepn. of 1-thioarylanthraquinone 2-carboxylic acids, which are starting materials for the production of anthraquinonethioxanthenes. The thio ethers which are formed by the action of 1 mol. of the sulfate of 2,6- or 2,7-tetraazoanthraquinone on 2 mols. of 1-mercaptoanthraquinone-2-carboxylic acid or 2 mols. of 1-diazoanthraquinone-2-carboxylic acid on 1 mol. of 2,6- or 2,7-dimercaptoanthraquinone or by condensation of 2 mols. of 1-chloroanthraquinone-2-carboxylic acid with 1 mol. of 2,6- or 2,7-dimercaptoanthraquinone and which are the bis-(2'-carboxy-1'-anthraquinonyl)-2,6-2,7-dimercaptoanthraquinones, furnish by cyclization valuable vat dyes different from the known dyes containing 3 anthraquinone radicals. In an example, 1-rhodanthraquinone 2-carboxylic acid (from diazoanthraquinone-2-carboxylic acid by the method Ger. 206,054) is heated with NaOH soln. and 2,5-dichloro-1-aniline is run in, and the mixture is heated. The 1-dichlorothiophenylanthraquinone-2-carboxylic acid is converted by heating to 90–100° into the corresponding thioxanthone, which dyes cotton a golden yellow from the vat. Other examples are given.

Intermediates and dyes. I. G. FARBENIND. A.-G. Brit. 291,361, May 30, 1927. 6-Dialkoxypheyl- and 4,6-dialkox-5-halophenyl-1-thioglycolic-2-carboxylic acids are prepd. from 3,5-dihydroxy- and 3,5-dihydroxy-4-halobenzoic acids, resp., by alkylation, nitration and reduction and substitution of the resulting amino group by the thioglycolic acid residue. 5,7-Dialkox- and 5,7-dialkox-6-halo-3-hydroxythionaphthenes are made by treating the thioglycolic carboxylic acids with alk. condensing agents and removing CO_2 or by treating with Ac_2O and removing the Ac group. Thio-indigoid dyes are prepd. by oxidation of the thionaphthenes or by coupling them or their α -anils or other α derivs. with usual components of the benzene, naphthalene, or anthracene series. Several examples are given.

Naphthoquinone derivatives. I. G. FARBENIND. A.-G. Brit. 291,340, May 28, 1927. 7-Acylamino-1,4-naphthoquinones (which may be used as dye intermediates) are made by oxidation of a 7-acylamino-1-hydroxynaphthalene or a substitution product. Several examples are given.

6-Amino-5-acenaphthenecarboxylic acid. WILHELM ECKERT (to Grasselli Dyestuff Co., Inc.). U. S. 1,697,111, Jan. 1. 6-Amino-5-acenaphthenecarboxylic acid can be made by reducing (suitably with FeSO_4 in ammoniacal soln.) the 6-nitroacenaphthene-5-carboxylic acid obtainable by nitrating 5-acenaphthenecarboxylic acid. The product may be used as an intermediate for making vat dyes. Various details are given.

Lakes. I. G. FARBENIND. A.-G. Swiss 127,452–127,454, Mar. 30, 1926. Addns.

to 122,815. The manuf. of a lake by the interaction in an acid medium of substances forming complex W compds. and a salt of the Et ester of tetraethylrhodamine is carried out in the presence of an acid of a greater degree of dissocn. than tartaric acid. In the example, a substrate is prepd. by mixing heavy spar with Na_2SO_4 soln. and pptg. with BaCl_2 and to this are added, in turn, specified amts. of a salt of the Et ester of tetraethylrhodamine, Na_2WO_4 , Na_2HPO_4 , and HCl (127,452). Lakes are prepd. in the same way from a salt of the Et ester of diethylhomorhodamine (127,453) and from a salt of tetraethyldiaminodiphenyl- α -monoethylaminonaphthylcarbinol (127,454). Cf. Brit. 265,032 (C. A. 22, 323).

Anthraquinone dyes. SOC. ANON. POUR L'IND. CHIM. A BAËLE. Fr. 641,748, Oct 3, 1927. Vat dyes of the anthraquinone series contg. cyanuric radicals as described in Fr. 552,266 are purified by a treatment with aq. solns. of hypochlorites, the colors obtained with the dyes being purer and brighter. Thus, the crude product obtained by condensing 2 mols. of 1-aminoanthraquinone with 1 mol. of $(\text{CN})_2\text{Cl}_2$ are treated with a soln. of NaOCl contg. 8% active Cl, purer yellow shades being afterwards obtained on cotton.

Anthraquinone derivatives. I. G. FARBENIND. A.-G. (Paul Nawiasky and Fritz Helwert, inventors). Ger. 469,135, Jan. 1, 1927. 1-Hydroxyanthraquinone or its derivs. are treated with caustic alkali in the presence of an org. solvent or suspension medium in the warm, preferably in the absence of O. Thus, PhNH_2 is heated to 160° , and 1-hydroxyanthraquinone with powd. K added with the max. exclusion of O. The mixt. is heated to the b. p. of PhNH_2 and stirred and the dye extd. in the usual way. Other examples are given.

Anthraquinone derivatives. SOC. ANON. POUR L'IND. CHIM. A BAËLE. Swiss 127,530, Feb. 12, 1927. Amino anthraquinone derivs. are prepd. by heating $p\text{-C}_6\text{H}_4(\text{NH}_2)_2$ and PhNMe_2 with a deriv. of the general formula 1-amino-4-x-anthraquinone where x is a residue replaceable by an aminoaryl residue. Thus, 1-amino-4-methoxyanthraquinone gives 1-amino-4-(4-aminophenylamino)anthraquinone, which dyes acetate silk green-blue and has a m. p. of $247\text{--}248^\circ$. Instead of PhNMe_2 , PhNO_2 , $o\text{-C}_6\text{H}_4\text{Cl}_2$ or naphthalene can be used.

Arylaminoanthraquinones. KARL ZAHN and PAUL OCHWAT (to Grasselli Dyestuff Corp.). U. S. 1,699,419, Jan. 15. Dyes are obtained by heating 5,8-dihaloquinizarin with primary aromatic amines either in the presence or absence of an acid binding agent. Reaction of aniline or of *p*-toluidine on 5,8-dichloroquinizarin produces the corresponding dianilino- or ditoluino-dihydroxyanthraquinones which can be easily converted into sulfonic acids that give on wool fast pure yellowish green dyeings.

Green dye of the anthraquinone series. JAMES OGILVIE (to National Aniline and Chemical Co.). U. S. 1,698,821, Jan. 15. By the sulfonation of 1,4-*p*-toluinoanthraquinone or a similar 1,4-diarylaminoanthraquinone in which the aryl groups are of the benzene series, with oleum of about 10-30% strength, in the presence of H_2BO_3 , a dark green dye is obtained which dyes wool from an acid bath yellowish blue-green shades.

Sulfamic acids of the anthraquinone series. I. G. FARBENIND. A. G. (Walter Duisberg, Winfried Hentrich, Ludwig Zeh and Fritz Baumann, inventors). Ger. 469,564, July 20, 1924. Aminoanthraquinones or their derivs. are sulfonated in the presence of NH_3 or primary amines. The examples describe the prepn. of sulfamates from 2-aminoanthraquinone, 1,4-diaminoanthraquinone, and 1,4,5,8-tetraminoanthraquinone. The product of the last example dyes wool and acetate silk in clear blue shades.

Anthracene dyes. I. G. FARBENIND. A.-G. Fr. 636,352, June 13, 1927. Dyes of the anthracene series are prepd. by treating with an acid or alk. oxidizing agent an anthrahydroquinone of the general formula

in which, R^1 denotes H or an alkyl group, R^2 the radical of a compd. capable of reaction with the H of the OH groups in the 9,10-positions of an anthrahydroquinone, e. g., a halosulfonic acid, a halogenated fatty acid, or a H_2SO_4 ester, and X a H or any univalent substituent. Several examples are given.

Tetrakisazo dyes. I. G. FARBENIND. A.-G. Fr. 637,743, July 15, 1927. Tetra-kisazo dyes are prepd. (1) by diazotizing aminodiazodyes of the type $R^1-N=N-R^2-N=N-R^3-NH_2$, where R^1 represents an amine, R^2 a middle component of the naphthalene series which is capable of being further diazotized, and R^3 a deriv. of α -naphthylamine or its sulfonic acids joined in the *p*-position to the amino group and contg. hydroxy groups substituted or free, (2) coupling with derivs. of 2-amino-5-hydroxy-naphthalene-7-sulfonic acid substituted or not in the 1- or 3-position and contg. diazotizable amino groups in the heteronuclear side chain, (3) diazotizing again and combining with methylketol, its analogs or substitution products, pyrazolones or derivs. of β -ketoaldehyde, 1,3-dihydroxyquinoline, sulfazones or salicylic acid or its derivs. The dyes give a clear green fast to light on cotton. In examples (1) 1-aminobenzene-2,5-disulfonic acid-azo-1-aminonaphthalene-7-sulfonic acid-azo-1-amino-2-ethoxynaphthalene-6-sulfonic acid is diazotized and coupled with (4-aminobenzoyl)-2-amino-5-hydroxynaphthalene-7-sulfonic acid. The product is diazotized and coupled with methylketolsulfonic acid; (2) 2-aminonaphthalene-4,8-disulfonic acid-azo-1-aminonaphthalene-azo-1-amino-2-methoxynaphthalene-6-sulfonic acid is diazotized and coupled with (3-aminophenyl)-1,2-naphthimidazole-5-hydroxy-7-sulfonic acid, again diazotized and coupled with 1-(4-carboxyphenyl)-3-methyl-5-pyrazolone. A further example and lists of substituents in the examples are given. Cf. C. A. 23, 992.

After-chromable triphenylmethane dyes. I. G. FARBENIND. A.-G. Swiss 127,531, Apr. 29, 1927. Two mols. of *o*-cresotic acid are condensed with one mol. of 4-benzyl-amino-3-sulfobenzaldehyde or a salt thereof, and the obtained leuco base is oxidized. The new dye is a red powder, giving a deep red color in alk. soln. It dyes wool a red-blue in acid soln. and on chroming, a red-purple which is fast to light.

Indigoid dyes. I. G. FARBENIND. A.-G. Brit. 291,825, Feb. 3, 1927. A monoalkyl, monoaralkyl or monoaryl ether of 4-mercapto-1-naphthol, in which the hydrocarbon radical is attached to the S, is condensed with a reactive α -deriv. of an isatin, such as isatin chloride or anilide; e. g., 5,7-dibromisatin chloride is condensed with -methylmercapto-1-naphthol or 4-*p*-tolylmercapto-1-naphthol (which is obtained by condensing *p*-tolylsulfur chloride with 1-naphthol). The products dye cotton from blue to greenish blue shades. Cf. C. A. 23, 716.

Vat indigoid dyes from dihaloalkylisatins. CARL KRAUSS (to Grasselli Dyestuff Co.) U. S. 1,698,233, Jan. 8. Dyes giving fast blue shades are produced by condensing a dihaloalkylisatin compd. contg. a reactive substituent in α position with a dihaloalkylindoxyl or (preferably) by reducing dihaloalkylisatin compds. contg. a reactive substituent in α position. Such reactive substituents may be halogens (particularly Cl), S, arylamino groups, alkoxy groups, etc. Examples are given of dyes produced from the reduction with H_2S of the α chloride formed by reaction of PCl_5 on a soln. in $PhCl$ of 5,7-dichloro-6-methylisatin or 4,6-dimethyl-5,7-dichloroisatin.

1-Amino-4-hexahydroanilinoanthraquinone-2-sulfonic acid. I. G. FARBENIND. A.-G. Swiss 127,030, Apr. 4, 1927. 1-Amino-4-hexahydroanilinoanthraquinone-2-sulfonic acid is obtained by the action of hexahydroaniline on 1-aminoanthraquinone-2-sulfonic acid suitably substituted in the 4-position, for instance with halogen or OH. The product dyes wool blue.

Dyes from 1,3,3-trimethyl-2-methyleneindoline. I. G. FARBENIND. A.-G. Swiss 127,037, Apr. 29, 1927. 1,3,3-Trimethyl-2-methyleneindoline or a substitution product thereof is treated in presence of a condensing agent, such as Ac_2O , with ester or salts of HNO_3 . The products dye natural or artificial silk or tannin-mordanted cotton in greenish yellow shades.

Mordant dyes. DURAND & HUGUENIN A.-G. Swiss 127,445 and 127,446, July 7, 1926. Addns. to 123,930. Mordant dyes are prepd. by coupling diazotized *p*-amino-*o*-sulfobenzeneazo-*o*-cresotinic acid with *o*-cresotinic acid (127,445) and with *m*-cresotinic acid (127,446). *p*-Amino-*o*-sulfobenzeneazo-*o*-cresotinic acid may be prepd. by coupling diazotized monoacetyl-*p*-phenylenediaminesulfonic acid with *o*-cresotinic acid and eliminating the Ac group, or by coupling diazotized *p*-nitroaniline-*o*-sulfonic acid with *o*-cresotinic acid and reducing the NO_2 group. Cf. Brit. 255,086 (C. A. 21, 2804).

Reducing mordant on indigo. ADMINISTRATION OF THE IVANOV-VOZNESENSKII GOVERNMENT TEXTILE TRUST. Russ. 4586, Sept. 15, 1924. Indigo-dyed goods are printed by use of mixts. of hyposulfite or sulfoxylate compds. stable at low temp. and metal ammonia compds. which are not decompd. by H_2O or a mixt. of the same metal salts with ammonium salts, or a mixt. of the same metal oxides and ammonium salts with or without the addn. of anthraquinone, followed by a hot alkali wash, water wash, acid wash and final water wash.

Treatment of cellulose derivatives. GEORGE H. ELLIS (to Henry Dreyfus). Can. 285,978, Dec. 25, 1928. Materials made of or contg. cellulose acetate have applied thereto metallic mordants in the form of thiocyanates, the concn. of thiocyanate radical present being in excess of that chemically equiv. to the mordant metal radical, and subsequently applying a dyestuff.

Treatment of insoluble or difficultly soluble dyes. I. G. FARBERIND. A.-G. Swiss 127,223, Apr. 16, 1927. The finely divided state of freshly prep'd. insol. or difficultly sol. dyes is preserved by pasteing them with an alkylcellulose. Examples describe the treatment with methylcellulose of azo dyes from (1) 2-hydroxy-3-naphthoic acid anilide and diazotized 4-nitro-2-aminobenzoic acid methyl ester, and (2) β -naphthol and diazotized 3-nitro-4-aminotoluene.

Yellow dye containing chromium. I. G. FARBERIND. A.-G. (Hans Kämmerer, inventor). Ger. 468,576, Feb. 10, 1927. The dye from diazotized metanilic acid and salicylic acid is treated with chroming agents, for instance with $(\text{HCOO})_2\text{Cr}$.

Green dischargeable dyes for silk. ERNST FELLNER (to Grasselli Dyestuff Corp.) U. S. 1,699,427, Jan. 15. Dyes producing level green shades on silk, fast to washing but dischargeable to a perfectly clean white, are obtained by diazotizing aromatic monoacid diamines or their sulfonic or carboxylic acids, combining the diazo comp'd. thus produced with 1,2-aminonaphthol ethers or their sulfonic acids, rediazotizing the monoazo dye thus formed and further coupling with *peri*-amino-naphthol-, *peri*-dihydroxynaphthalenesulfonic acids or their derivs. Several examples are given.

Dyes for acetate silk. BRITISH DYESTUFFS CORP., LTD., A. SHEPHERDSON, W. W. TATUM and F. LODGE. Brit. 291,814, Dec. 13, 1926. Symmetrical 1,4-dialkyldiaminoanthraquinones are converted into products contg. fewer alkyl groups by treatment with H_2SO_4 at temps. above 150° or in the presence of H_3BO_3 at 130 - 150° . The dye thus formed from 1,4-dimethyldiaminoanthraquinone dyes acetate silk bright violet-blue shades.

Dyeing. HENRY DREYFUS. Fr. 641,566, Sept. 16, 1927. Compds. of or contg. cellulose esters are dyed with an aq. dispersion of an insol. or relatively insol. dye, obtained by grinding in a colloid mill or dissolving in an org. solvent and pouring into water, with or without a treatment with a solubilizing agent. Examples are given.

Dyeing. I. G. FARBERIND. A.-G. (Georg Wolfsleben, inventor). Ger. 467,060, Sept. 7, 1926. A triazo dye is prep'd. by diazotizing *p*-aminophenylazogamma acid, coupling with gamma acid and further diazotizing with *m*-phenylenediamine. Thus, nitroaniline is diazotized, coupled with gamma acid and reduced. The resulting aminophenylazogamma acid comp'd. is diazotized, further coupled with gamma acid and further diazotized with *m*-phenylenediamine. The resulting dye is bronze-black and sol. in water.

Dyeing. I. G. FARBERIND. A.-G. (Richard Fischer, inventor). Ger. 469,326, Aug. 17, 1926. In dyeing with leuco ester compds. of the indigo series and other vat dyes, the vat is mixed with dextrin, size, starch paste or similar substances to prevent uneven drying of the dye in the material.

Dyeing with vat dyes. D. GARDNER. Brit. 291,828, Feb. 5, 1927. In dyeing with vat dyes, such as indigo, the dye is reduced with a titanous salt such as titanous chloride and is used in an aq. non-alk. bath. Dyes may be used which are prep'd. as described in Brit. 291,827 (preceding abstract). The process may be applied to all kinds of fiber including wool and silk. For dyeing vegetable fibers or artificial silk, a substantially neutral bath is preferable such as may be obtained by dissolving the dye in an aq. soln. of glucose.

Dyeing cellulose. SOC. CHIMIQUE DES USINES DU RHÔNE. Swiss 127,542, June 24, 1927. Cellulose esters are colored by forming the pigment in the body of the soln. of the ester, and then sepg. the colored ester. Thus, cellulose acetate is dissolved in acetone and FeCl_3 added. After stirring, $\text{K}_4\text{FeC}_6\text{N}_6$ is added. The cellulose acetate is then pptd., washed and dried. Other examples are given. The pigment may be org. or inorg.

Dyeing acetylcellulose. BRITISH DYESTUFFS CORP., LTD., JAMES BADDILEY, JAMES HILL and ARNOLD SHEPHERDSON. Fr. 33,009, Feb. 5, 1927. Addn. to 623,761. The final phase in the prepn. of a dye is carried out in the presence of a dispersing agent and the paste obtained is dried. In examples, 5-nitro-2-anisidine is combined with PhNEt_2 in the presence of ligninsulfonic acid, and the product ground to a powder. In the same way, aniline \rightarrow α -naphthylamine is diazotized and coupled with PhOH in the presence of ligninsulfonic acid, mixed with the condensation product of sulfo-naphthalene and CH_2O , dried and powdered.

Dyeing cellulose derivatives. HENRY DREYFUS. Fr. 642,473, Oct. 14, 1927.

Cellulose derivs. are treated with a swelling agent such as HCOOH , AcOH , glycolic acid, lactic acid, EtOH , Me_2O , diacetone alc., diacetin, phenol or a thiocyanate, before dyeing, printing or stenciling with insol. or relatively insol. org. dyes which may be solubilized in known manner. Cf. C. A. 23, 718.

Dyeing cellulose esters. SOCIÉTÉ CHIMIQUES DES USINES DU RHÔNE. Fr. 33,001, Feb. 9, 1927. Addn. to 619,764. Cellulose esters are dyed with lakes by forming the lake in a soln. of the ester and isolating the ester from the soln. In an example, cellulose acetate is dissolved in acetone contg. eosin. A slight excess of $(\text{AcO})_2\text{Pb}$ in soln. in water is added. The colored cellulose acetate is pptd. with water, and may be used for varnishes, films, etc.

Dyeing cellulose esters. HENRY DREYFUS. Fr. 642,330, Sept. 16, 1927. Cellulose esters of carboxylic acids, other than AcOH , such as the formic, propionic or butyric esters, in the form of artificial silk, etc., are dyed, printed or stenciled with aq. dispersions of insol. or relatively insol. dyes. Several examples are given, the dispersion agents used being Na or NH_4 sulforicinolate, Na naphthalenesulforicinolate, Turkey red oil or glue.

Dyeing cellulose esters and ethers. H. DREYFUS. Brit. 291,118, Nov. 23, 1926. Materials such as cellulose formate, acetate, propionate or butyrate, "immunized cotton," or cellulose methyl, ethyl or benzyl ethers or condensation products from cellulose and glycols, are dyed, printed, stenciled or otherwise colored with compds. in which an aryl dye nucleus is linked to one or more thiocyanate, cyanate, isothiocyanate, isocyanate or simple or aliphatically substituted urea or thiourea residues. Numerous details and examples are given.

Dyeing cellulose esters and ethers. H. DREYFUS. Brit. 291,816, Dec. 14, 1926. Org. substitution derivs. of cellulose such as described in Brit. 291,118 (preceding abstract) are dyed, printed or otherwise colored with compds. in which an aryl dye nucleus or component is linked, directly or indirectly, to one or more thiourethan or substituted thiourethan residues. The dyes or components may be prepd. by heating the corresponding isothiocyanate compds. with alcs. or with alc. caustic alkali, by treating the corresponding thiourea chloride compds. with alc. or alcoholates, by treating halogen compds. with esters of sulfocarbamic acid, or in some cases by boiling an amino compd. with an alc. and CS_2 . Examples are given.

Dyeing and printing cellulose esters or ethers. I. G. FARBENIND. A.-G. (Erich Fischer and Erich Müller, inventors) Ger. 469,514, Apr. 24, 1926. The dyes employed are monoazo dyes prepd. by coupling suitable *p*-substituted phenols with diazo compds. of the C_6H_5 or C_{10}H_7 series having one SO_3H group at the most. An example describes the dyeing of acetate silk with the dye from *p*-phenylenediamine and *p*-cresol, and the use of the dyes from acetyl-*p*-phenylenediamine and *p*-cresol, *m*-chloroaniline and *p*-cresol, and *p*-phenylenediamine-*o*-sulfonic acid and *p*-cresol is referred to. Yellow shades are produced in each case.

Dyeing textiles containing cellulose derivatives. HENRY DREYFUS. Fr. 32,949, Jan. 28, 1927. Addn. to 627,071. Org. derivs. of cellulose are dyed, printed or stenciled with azo compds. contg. one or more amino groups substituted by one or more aliphatic side chains, each contg. two or more OH groups but no COOH groups. The dvestuffs may be solubilized by the known solubilizing agents, and protective colloids may be added to the dye baths. In examples (1) *p*-nitroaniline is condensed with chlorobutylene glycol, reduced, diazotized and coupled with α -naphthylamine giving a dye which may be diazotized on the fiber, e. g., with *o*-dihydroxypropylaniline, (2) the product obtained by coupling diazotized picramic acid with dihydroxypropylaniline, (3) the product of condensation of 2,4-dinitrochlorobenzene with δ -amino- α,β -dihydroxypropane reduced to 2-amino-4-nitrodihydroxypropylaniline, diazotized and coupled with *p*-xylylidine.

Dyeing textiles containing cellulose derivatives. HENRY DREYFUS. Fr. 32,948, Jan. 28, 1927. Addn. to 627,072; Can. 285,799, Dec. 25, 1928. Org. derivs. of cellulose are dyed, printed or stenciled with compds. in which an aryl dye nucleus or component thereof is linked directly or indirectly to one or more thiourethan or substituted thiourethan residues. Dyes of the anthraquinone, nitrodiarylamine, nitrodiarylmethane and azo series are specified; in the latter case the dyes may be applied in substance or developed on the fiber. Examples of dyes used are (1) 1-acetylaminanthraquinone-4-thiourethan, obtained by heating 1-acetylaminanthraquinone-4-isothiocyanate (from 1-acetylaminanthraquinone and CSCl_2) with EtOH or alc. KOH , (2) the disazo dye obtained by diazotizing phenylazo- α -naphthylamine and coupling with salicylic acid-5-thiourethan. Other examples are given.

Dyeing, printing or stenciling materials made of or containing cellulose derivatives.

HENRY DREYFUS. Can. 285,798, Dec. 25, 1928. Materials made of or contg. org. substitution derivs. of cellulose are dyed or otherwise colored with compds. comprising one or more aliphatic hydroxy ether or hydroxy thio ether groupings, *i. e.*, with compds. in which an aryl dye nucleus is linked through O or S with an aliphatic side chain or chains contg. 1, 2, 3 or more OH groups.

Dyeing artificial silk. KALLE & Co. A.-G. (Bruno Helmert, inventor). Ger. 469,513, June 5, 1925. Artificial silk made from esters or ethers of cellulose or its conversion products is dyed with azo dyes prepd. from nitrated hydroxydiazo compds. and aromatic amines or phenols or their substitution products. In the examples, acetate silk is dyed with dyes prepd. from diazotized picramic acid and β -naphthylamine, α -naphthylamine, *m*-phenylenediamine, and α -naphthol with the production of yellow, violet, orange and brown shades, resp. The dyes prepd. from amines can be diazotized and further coupled on the fiber.

Dyeing automatically and continuously ribbons of artificial silk fibers or yarn. BERTETTO MANUELLO, 2ND. Ital. 244,794, April 13, 1926. Mech. features.

Dyeing animal fibers. EDMOND DU BOIS (to Chemische Fabrik vorm. Sandoz) U. S. 1,698,226, Jan. 8. Animal fibers are treated with acylating agents such as *p*-toluenesulfonyl chloride in order to increase their affinity for dyes.

Process and apparatus for dyeing hat bodies. ADOLF SINDERMANN. Austrian 109,814, Jan. 15, 1928. The dye is applied in dry powder form, suitably by blowing through fine nozzles on to the damp bodies. Cf. C. A. 23, 994.

Dyeing apparatus. FRANK DAVIS. Fr. 641,138, Sept. 15, 1927. A coned dye soln. or reagents are led through a pipe immersed in the dye bath and added to the dye bath at the bottom along with a certain amt. of the liquid of the bath and aspirated by the said pipe from one side of the bath, the liquid thus revived, reentering the bath at the opposite side.

Dyeing apparatus, especially for natural- or artificial-silk stockings. U. PORNITZ & Co. A.-G. Ger. 469,600, Aug. 19, 1925.

Vat for bleaching and dyeing. FIRMA JOS. RIEDEL. Ger. 469,123, Feb. 11, 1927. Details of securing the acid-proof lining.

Apparatus suitable for dyeing goods in long lengths in a vat through which dye liquor is circulated. FRANK DAVIS. U. S. 1,699,391, Jan. 15.

Apparatus for dyeing sheets of fabric a uniform shade with circulating dye liquor. FRANK W. CLARK. U. S. 1,698,778, Jan. 15.

Printing colors. I. G. FARBENIND. A.-G. Fr. 642,079, Oct. 7, 1927. Pure nitrosamine printing colors are obtained by dissolving the colors in appropriate org. solvents, filtering and removing the solvents. Thus, to a soln. of 50 parts of the anilide of 2,3-hydroxynaphthoic acid, and 14 of NaOH in acetone, the Na salt of nitrosamine corresponding to 31.2 parts of *m*-nitro-*p*-toluidine is added, the soln. filtered and the solvent removed. A dry yellow compd. is obtained easily sol. in water without a harmful residue.

Luster or color differences in rayon textures by difference in dye absorption qualities. NAAMLIOOZE VENNOOTSCHAP NEDERLANDSCHE KUNSTZIJDEFABRIEK. Dutch 18,635, Sept. 15, 1928. Previous to the weaving part of the rayon (viscose) is heated (*e. g.*, 24 hrs. in glycerol at 150°) or oxidized (2 hrs. at room temp. in dil. NaClO-HCl soln.) so as to give it smaller or larger absorptive power for the dyeing after the weaving process.

Treating textiles. RENÉ VAN BUGGENHOUDT and RENÉ HOMMEYER. Fr. 642,492, Oct. 17, 1927. See Brit. 279,137 (C. A. 22, 2847).

Finishing textile materials. H. T. BÖHME A.-G. Brit. 291,094, May 27, 1927. Deleterious effects upon fabrics resulting from the liberation of free sulfuric acid during calendering and drying at elevated temps. are avoided by using, instead of the usual Turkey-red oil, the product obtained by treating castor oil or other suitable fats or oils or their free acids with H₂SO₄ in the presence of org. acid anhydrides or chlorides, *e. g.*, Ac₂O.

Producing patterns on vegetable textile material. EMIL GMINDER. Ger. 469,601, Mar. 14, 1928. The material, *e. g.*, cotton fabric, is mercerized and put under tension. The mercerizing agent is then neutralized at certain parts, *e. g.* with dil. HCl, with the fabric still under tension, and the tension is then released.

Impregnating textile materials with condensation products of phenols and formaldehyde. FOOTAL BROADHURST LEE CO., LTD., R. P. FOWLES, J. T. MARSH AND F. C. WOOD. Brit. 291,474, Dec. 1, 1928. Various fabrics of natural or artificial cellulosic material are rendered "non-creasing" or "non-crumpling" when crushed or folded under pressure by impregnating them with a condensation product of a phenolic compd.

and CH_3O . The compds. may be formed by condensation within the material. Various details and modifications are given.

Forming synthetic resins within textile materials. TOOTAL BROADHURST LEE CO., LTD., R. P. FOULDS, J. T. MARSH, F. C. WOOD, H. BOFFEY and J. TANKARD. Brit. 291,473, Dec. 1, 1926. Yarns or fabrics of cotton, silk, ramie, jute, hemp, artificial silk, etc., are rendered less susceptible to creasing or crushing, while retaining their original suppleness, by impregnating them with components for producing phenol- CH_3O or urea- CH_3O resins and then forming the resins within the material. Many details are given.

Embossing fabrics. C. DREYFUS (to British Celanese, Ltd.). Brit. 291,445, June 3, 1927. In order to produce permanent embossed effects on circular knitted fabrics or stockings of thermoplastic derivs. of cellulose such as the acetate, formate, or propionate, or methyl or ethyl ethers of cellulose, either alone or mixed with other materials such as cotton, wool or silk or artificial silk of the "cellulose type," the fabric is dampened with a swelling, softening or plasticizing agent such as a soln. of acetone, MeOAc , triacetin, *p*-toluenesulfonamide, diethyl phthalate, alkylated xylene or sulfonamide and then, while still in the double thickness, is subjected to an embossing operation.

Mercerizing or similar treatments of fabrics. F. THIES. Brit. 291,130, Feb. 18, 1927. Mech. features. An app. is described.

Apparatus for steam treatment of printed fabrics. HEINZ BACKHAUS. Austrian 110,386, Mar. 15, 1928. The steam is circulated across the fabrics by blowing and suction devices.

Apparatus (with a heated "nichrome" roller) for singeing and drying fabrics. A. W. MACHLET. Brit. 291,300, Dec. 3, 1927.

Cold-washing process for fabrics, etc. HULDREICH H. VONTOBEL. Swiss 127,227, May 12, 1927. The fabrics are washed in a cold aq. soln. contg. soda, soap, borax, enzymes such as peroxidase and tyrosine and heavy metal salts such as $\text{Al}_2(\text{SO}_4)_3$ and FeSO_4 . Cf. C. A. 22, 3789.

Fabric for making hats. GEORGE E. MCLEAN. U. S. 1,697,877, Jan. 8. A fabric specified with plies of regenerated cellulose fiber and linen and an intermediate ply of cotton.

Improving the tensile strength of vegetable fibrous materials. PAUL B. COCHRAN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,699,779, Jan. 22. Materials such as cotton tape for elec. insulation are exposed to the action of ozonized air while heated (suitably at a temp. of about 75–150°).

Increasing the wettability of vegetable or animal fibers. I. G. FARBENIND. A.-G. Fr. 642,222, Oct. 13, 1927. Sulfonic acids of aromatic compds. particularly of the C_{10}H_8 or tetrahydronaphthalene series, alone or combined among themselves or in combination with hydrocarbons, alcs. or ketones are incorporated in fibers to increase their wetting and absorbing properties.

Artificial fibers resembling wool. E. K. SCOTT. Brit. 291,120, Nov. 24, 1926. Materials as used for artificial silk manuf. are extruded and while still in a plastic condition are subjected to mech. treatment which will produce curls, spirals or crimps along their length and will also produce on the surface of the filaments serrations, projections or nodules. An app. is described.

Rendering jute woolly and resistant to washing. GIAN CARLO GUARNIERI. Ital. 245,907, October 3, 1927. For this purpose and to render the jute fiber capable of being milled with natural wool, it is treated in a lukewarm fermentation bath with cultures of ferments capable of strongly reacting on the lignin of the fiber. A Cl and NaOH bath then gives the woolly appearance, curliness and resistance to boiling H_2O and milling. An acidified bath of antichlor is then used, followed by washing and treatment with an emulsified fat for giving softness and luster.

Finishing or dressing composition for jute. JOSEF GÜRTLER. Austrian 110,864, May 15, 1928. The compn. comprises semisapond, colophony, alkali salts contg. water of crystn. and NH_3 soln. A typical compn. comprises, in 100 parts of water, 35 parts of colophony sapond. at 70–80° with 3 parts of NaOH , 2 parts of cryst. Na_2CO_3 and 5 parts of NH_3 soln. (0.91), to which addns. of Na_2SO_4 , NH_4 salts, AcONa and NaCl may be made.

Making artificial silk waste wool-like. ARTILIO DEL MASTRO. Ital. 244,247, Jan. 28, 1926. The waste is immersed in a 20% soln. of Na hyposulfite at 30°. After $\frac{1}{4}$ hr the excess of soln. is eliminated and 25° Bé. H_2SO_4 is added in slight excess over the theory (4 times the wt. of the waste) while agitating. After 15 min. the fiber is dark yellow, and is taken out, washed completely, pressed and dried. A slight soaping

renders it less hard. The shine disappears, and better calorific properties and a wooly appearance are acquired, without weakening occurring and without elasticity being reduced.

Treating artificial silk. HENRY DREYFUS. Fr. 637,764, July 16, 1927. Fabrics made of or contg. cellulose esters or ethers are rendered less liable to develop faults due to want of cohesion by a single or repeated impregnation at 80–100° with aq. solns. or dispersions contg. at least 10% of one or more of the following: (1) higher fatty acids such as oleic, stearic and palmitic acids or sulfonated or other derivs. thereof, (2) sulfo-aromatic fatty acids, such as sulfophenylstearic, sulfohydroxyphenyl or sulfonaphthylstearic, (3) sol. resin soaps. After impregnation the fabrics are piled and rolled and left for some time. Fr. 637,765 describes a treatment for the same purpose with one or more org. substances having a solvent or solute action upon the fibers. Examples are (a) hydrocarbons of the paraffin, aromatic, naphthene or terpene series and their hydrogenation and halogenated derivs., (b) alcs. and phenols of the various chem. series and their derivs., (c) amino compds., (d) ketones and aldehydes. Lists of substances under each heading are given.

Apparatus for treating yarn with paraffin. A. BÜRK and K. WILDER. Brit. 291,250, June 30, 1927.

Washing yarn. CARL RUDOLF LINKMEYER. Ger. 469,004, Mar. 1, 1925. Suspended skeins of yarn, especially artificial silk, are washed by intermittent irrigation.

Bleaching. H. GOLDARBEITER. Brit. 291,743, June 7, 1927. Catalysts such as Ni salts, Co salts, Ag salts or $K_2FeC_6N_8$ are used to control the speed of the reaction in bleaching vegetable fibers, feathers, skins, furs, bristles, etc., by H_2O_2 in the presence of an alkali.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Colloid-chemical problems (in paint industry). A. V. BLOM. *Farben-Ztg.* 33, 1969–72(1928).—A lecture dealing with general aspects of wetting power and interfacial tension applied to pigments and paints. B. C. A.

Ultra-violet light and its use in accelerated weathering tests on paints. E. BECKER. *Farben-Ztg.* 33, 2232–4(1928).—In a general theoretical discussion on the nature of electromagnetic waves it is shown that the use of the light emitted by the Hg-vapor lamp to represent the action of sunlight in accelerated weathering tests on paints, etc., must give erroneous results. The Hg-vapor lamp emits short-wave radiation down to λ 185 μ , while the radiation from the sun contains no waves shorter than 300 μ . It follows, therefore, that the greater energy quanta liberated by the former source induce reactions that cannot occur under the influence of sunlight. It is suggested that filtration of the Hg-vapor emission through suitable glass filters in order to eliminate the wave region not present in sunlight would render the artificial source applicable to accelerated weathering tests. B. C. A.

"Wetting-out agents" for the paint industry and their investigation. A. NOLL. *Farben-Ztg.* 33, 2293–9(1928); cf. C. A. 22, 710, 3795.—A general dissertation on the chem. nature of wetting-out and emulsifying agents used in water-paint manuf. (chiefly Na salts of complex org. sulfonic acids). Details of the compn., properties, purification and fluorescence characteristics of various com. products of this type, e. g., Nekal, Leonil, Betan, Majamin, Algosol, etc., are given, and the stability of emulsions formed by the aid of various combinations of these is tabulated. B. C. A.

Color standardization and testing in the paint and color industry. II. I. A. JORDAN, et al. *J. Oil Colour Chem. Assoc.* 11, 383–95(1928).—A discussion of different methods of color measurement and efforts to use them in the paint and dye industries. The effect of surface condition such as gloss on the color sample under examn. is large and interferes with exact measurement. Each color sample should be given a coat of high-gloss varnish, so that all measurements are made under a const. gloss factor.

R. J. MOORE
Standardization of dry colors. F. A. WERTZ, et al. *Am. Paint Varnish Manufs. Assoc. Circ.* No. 341, 874–9(1928).—The value of standardization is problematical but the committee (Federation Paint Varnish Clubs) recommends standard procedures for testing and a standardized nomenclature. Accelerated fading tests are included on various samples of chrome yellows and greens.

R. J. MOORE
Discoloration of paints and its prevention. ANON. *Farbe u. Lack* 1928, 578, 596.—

A review of the causes and prevention of discoloration due to the nature of the pigment and to various external influences.

G. G. SWARD

Experiments on colors fast to flue gas. A. JUNK. *Korrosion und Metallschutz* 4, 230-4(1928).—Various paints on various priming coats were exposed to vapors given off in coke quenchers. The best primers were those not attacked by the vapors such as red oxide or iron mica. White lead was almost as good while Pb oxides did not fare as well. Better results were obtained by using several coats of the covering paints and no primers.

B. E. ROETHELI

The distribution of pigment in paint films. HANS WOLFF. *Farben-Ztg.* 34, 669-70 (1928).—W. removed films of white lead and of ZnO paints in 10 steps by rubbing with pure SiO_2 and H_2O . The ether-sol. soaps and total PbO or ZnO were detd. in each layer. With white lead paints the outer and inner layers contained much more pigment than the intermediate layers. With ZnO paints only the layer next to the panel contained the greater quantity of pigment. The white lead paints showed evidence that neutral PbCO_3 had been formed in the outer layers. The results are further proof that paint films are not necessarily homogeneous.

G. G. SWARD

Oil consumption in the grinding of pigments. A. EIBNER. *Farben-Ztg.* 34, 725-9(1928).—The nomenclature of oil absorption should be standardized. The order of magnitude of the difference in the oil absorption of most pigments disappears if it is expressed as a vol. percentage. In order to clarify the situation, there are needed more accurate data concerning the quantity of oil necessary to form a paste (artists' colors), the quantity necessary to convert this paste to a brushable paint and the effect of the structure of the pigment. A close observance of the 3 stages in the absorption of oil by a pigment should be of value. These stages are the "crumbly," "critical" and "paste."

G. G. SWARD

Iron oxide pigments. A new process of manufacture. G. C. *Rev. prod. chim.* 31, 878-9(1928).—A soln. of FeSO_4 obtained from H_2SO_4 and Fe plates is spray dried in a hot chamber. The finely divided material is calcined by use of a rotary furnace heated by coke. The exhaust gases are used in the spray chamber. The SO_2 is oxidized to SO_3 by the presence of the Fe_2O_3 , and recovered as H_2SO_4 .

P. THOMASSET

A study of red lead. A. JUNK. *Farben-Ztg.* 34, 671-6(1928).—The sp. gr. of ordinary red lead was slightly higher (8.7-9.0) than that of the highly dispersed (8.5-8.7). The av. diam. of the former was over 5μ , of the latter from 2 to 5μ . Paints made from the former contained 15% oil compared with up to 28% for paints from the latter. The spreading quality ($5.7-6.9 \text{ m}^2/\text{kg}$) of the former was approx. half that of the latter ($8.2-13.25 \text{ m}^2/\text{kg}$) but with twice the pigment concn. per unit area probably affords twice the protection. In general, pigments contg. the most PbO_2 produce the least thickening in paints, 32% PbO_2 being recommended as a minimum. The settling of the pigment in the paint is inversely proportional to the thickening. An accelerated thickening test is carried out by heating the paint at 80° for 4 hrs.

G. G. SWARD

Pigment and vehicle. V. G. JOLLY. *J. Oil Colour Chem. Assoc.* 11, 361-75 (1928).—Relationships between pigment and vehicle are discussed which influence the character and properties of paints. Some expts. are cited of pastes thinned with various paint media and examd. periodically for settling. A medium oil enamel varnish contg. a poor grade Congo and petroleum thinners gave hard settling. The same varnish with turpentine as thinners gave much less and soft settling. The same varnish with petroleum thinners but a high-grade Congo gave soft settling. The use of various wetting agents is discussed. A slight modification of Gardner's mobilometer is described.

R. J. MOORE

Testing paint and varnish. HANS WOLFF. *Farben-Ztg.* 34, 732-4(1928).—Paints and varnishes which prove superior in one test may not do so in another and the early history of a coating is of more importance than usually recognized. W. advocates the deductive or statistical method of judging the probable merits of a coating.

G. G. SWARD

Auer's conception of the drying of oils. A. EIBNER. *Farben-Ztg.* 33, 2165-9 (1928).—The "gas-coagulation" theory is criticized mainly on the grounds that in its evolution Auer has ignored the work of earlier investigators on the individual characteristics of various oils, the hydrophilic nature of linseed oil films, etc. Some of the author's expts. in this field are briefly recapitulated.

B. C. A.

Tung oil. HENRI BLIN. *Mat. grasses* 20, 8370-2(1928).—Characteristics, production and uses of tung oil are described.

P. THOMASSET

Oil conversion. AMASA BOWLES. *Paint Oil Chem. Rev.* 86, No. 22, 10(1928).—The classes of condensation products suitable for varnish products are briefly reviewed.

A resin is described which is a combination of vegetable oil and a coal-tar product. This resin reacts with tung oil, changing the latter from an oxidizing oil to a gum or oleoresin through polymerization.

R. J. MOORE

Production of flat oil varnishes. F. WILBORN. *Farben-Ztg.* 33, 2169-70(1928).—Various substances are added to oil varnishes to produce a "matt" finish, e. g., waxes, $\text{Al}(\text{OH})_3$, MgCO_3 , kaolin, Al stearate, palmitate, resinate, Zn stearate, etc. The properties and suitability of the various types are discussed.

B. C. A.

Nitrocellulose finishes. BERTRAM CAMPBELL. *Ind. Chemist* 4, 522-6(1928).—The article includes accounts of manuf. of nitrocellulose, the addition of resins, the nature and effect of softening agents, the selection of pigments and of solvents and diluents. The factors affecting the durability of nitrocellulose finishes and methods for evaluating the durability of the finish are discussed.

F. G. R. ARDAGH

Cellulose ester solvents. H. WOLFF, G. ZEIDLER AND W. TOELDT. *Farben-Ztg.* 33, 2228-32, 2301-4(1928).—In dealing with cellulose ester solvents in connection with lacquer manuf., considerable misapprehension has been caused by confusing "solvent power" of a solvent with a more important factor of "power to withstand diln. by non-solvents without pptn. of the nitrocellulose." This diln. factor should be correlated with a definite end-concn. of nitrocellulose in the soln., results being obtained indirectly by graphical methods exemplified in the present communication by the behavior of solvents of the glycol type with respect to various diluents and qualities of nitrocellulose. In this respect as well as in considering viscosity of soln. and rate of evapn. of solvent, it is shown that the influence of non-solvent and of concn. of soln. must be taken into account if results of any practical value in lacquer technology are sought. The relative softening effect of solvents on oil undercoats is also discussed.

B. C. A.

Testing of finished lacquers. J. D. JENKINS AND P. R. CROLL. *Ind. Eng. Chem.* 19, 1356-8(1927).—Description of the equipment and cycle in use at the Milwaukee laboratories of the Pittsburgh Plate Glass Company for accelerated exposure tests and discussion of 3 physical tests: tensile strength, paper curling and sanding.

ALBERT L. HENNE

Albertol synthetic resins. T. HEDLEY BARRY. *Ind. Chemist* 4, 501-4(1928).—In previous articles B. described the coumarone and glyptal types of resins (*Ibid* 3, 431, 479(1927)) and Bryson the Bakelite resins (*Ibid* 1, 10, 73, 145(1925)). None of these replaces entirely the natural resins which are essential ingredients of oil varnishes. Some of the characteristics, advantages and limitations of these resins are discussed. The Albertol resins (Amberol in America) were developed mainly by K. Albert and his colleagues who at the outset used phenol-formaldehyde and natural resins together with a condensing agent sol. in the usual resin solvents. Much information on the prepn. of such resins, their properties and applications is given. Methods for making Albertols at low temps. are also described (thermo-setting Albertols). A bibliography is appended.

F. G. R. ARDAGH

Hardening and esterification of rosin. EWALD PYHALA. *Farben-Ztg.* 34, 616-7(1928); cf. *C. A.* 22, 3055.—The stoichiometry of the previously reported work is given in detail. The actual yields of ester based on the rosin used were with Ca glyceride 104, Mn glyceride 94.5, Ca phenolate 22.6, cresolate 19 and β -naphtholate 18.85, resp. The last 3 extremely low yields may be due to the extremely high viscosities of the melts.

G. G. SWARD

Organic solvents and rubber-lined plant (BRESSLER) 1. The gelling of fatty oils (SCHEIBER) 27. Electrodeposition of natural or synthetic resins (Brit. pat. 291,477) 4. Impregnating fibrous materials (Ger. pat. 469,602) 4. Solutions of resins, dyes, cellulose esters and ethers, etc. (Swiss pat. 127,241) 13. Grinding mill for paints, etc. (Brit. pat. 291,803) 1. Mill for grinding paint or other wet or dry materials (Brit. pat. 291,952) 1.

Lithopone. GUSTAV JANTSCH and PAUL WOLSKI (to I. G. Farbenind. A.-G.). U. S. 1,693,902, Dec. 4. Lithopone fast to light contains a Co salt, the Co content of which is equal to 0.02-0.5% of the Zn content of the lithopone. Salts of Cu or of Fe up to 0.5% also may be used.

Determination of the covering power of paints. V. V. CHERNOV. Russ. 4593, Feb. 29, 1928. A unit of wt. of paint after being thoroughly mixed with oil or similar material is placed between 2 glass plates and pressed. The transparency of a given paint is checked against other paints tested under the same conditions.

Glossy finish on lime paint. O. S. GOLOROVAKII. Russ. 5202, July 30, 1928.

Walls, ceiling, etc., of a room after being covered with lime paint for a second time are exposed to steam for a few hrs. before drying.

Anti-corrosive paints containing dehydrated oil gas tar and powdered aluminum or other metal powder. S. A. McMINN. Brit. 291,486, Jan. 28, 1927.

Colored nitrocellulose solutions or paints. I. G. FARBENIND. A.-G. Brit. 291,539, March 10, 1927. Nitrocellulose, wet with water, is ground and mixed with chrome yellow, fast Bordeaux red, or other suitable inorg. or org. coloring substance, in the presence of water or other "indifferent" liquid and in the absence of gelatinizing agents, and the resulting colloidal material is dried by heat, use of alc. or otherwise, and dissolved in a suitable solvent.

Red-lead paint. CARL D. FAHSEL. U. S. 1,697,388, Jan. 1. A light oil varnish and a paraffin oil are mixed with each other and then with boiled linseed oil as a primary vehicle, and red lead is mixed with this vehicle.

Red lead. S. A. ZADOLINE. Russ. 4579, Feb. 29, 1928. Massicot is oxidized and heated in a rotating drum by air heated in an oven above the highest temp. required for the reaction.

Apparatus for treating with carbon dioxide the spongy mass of basic lead acetate for obtaining lead white. D. I. LISOVSKII and A. A. SINTZOV. Russ. 4582, Feb. 29, 1928.

Pigment. C. DEGUDE. Brit. 291,355, May 30, 1927. A ZnSO_4 soln. is treated with Ba(OH)_2 to ppt. BaSO_4 together with Zn(OH)_2 ; the ppt. is dried and calcined to obtain a mixt. of BaSO_4 and ZnO .

Pigments from volatile metallic compounds. I. G. FARBENIND. A.-G. (Walter Hubardt and Marta Grote, inventors). Ger. 466,463, June 26, 1928. Pigments are prepd. from volatile compds. of Fe, Co or Ni, e. g., Fe carbonyl by thermal decompn. and superficial oxidation of the metal thus obtained.

Calcination of lithopone. FARBENFABRIKEN VORM. F. BAYER & CO. Ger. 418,258, Feb. 14, 1919. Lithopone is calcined in a rotating cylinder furnace by gases free from dust and oxygen which are preheated to a temp. slightly above the calcination temp.

Duplicating ink. RUDOLF JARMAI and EUGEN LORAND. Fr. 642,349, Sept. 7, 1927. The ink or color used for carbon papers, typewriting ribbons, etc., contains tramarine besides the usual wax, oil and resin and coloring substance.

Apparatus for grinding inks and colors. GUSTAV A. VASEL. U. S. 1,699,641, Jan. 2, 1929.

Polymerizing linseed oil. ALEXANDER SCHWARCMAN (to Spencer Kellogg & Sons, Inc.). Can. 285,744, Dec. 18, 1928. Light-colored, odorless, polymerized oil of low acid value is produced by heating a body of linseed oil to a temp. around $570-600^\circ\text{F}$. under vacuum while introducing into the body of oil a slow feed of gases free from O_2 and advantageously consisting of, or contg., CO_2 .

Treating, drying or semidrying oils with chromic acid. G. S. PETROV and Z. M. KALATZEV. Russ. 4577, Aug. 31, 1928. Such oils are brightened by treatment with bromates in the presence of H_2SO_4 which form insol. salts with the H_2SO_4 .

Driers. GEBR. BORCHERS A.-G. Ger. 466,046, May 26, 1927. Driers contg. Bi and Co in the ratio of 1:3 or 4 are obtained by heating Bi compds., e. g., oxide, acetate, citrate, with drying oils or rosin and adding Co compds., e. g., acetate or nitrate or *vice versa*. The Bi confers hardness on the film.

Coating compositions. FRANZ SCHMID. Austrian 111,037, May 15, 1928. The viscous liquid obtained by heating with S, for a sufficient time, a mixt. of wool fat with linseed oil, rape-seed oil, or like oil is mixed with dyes or fillers.

Varnish. ELMER E. WARE (to Acme White Lead & Color Works). U. S. 1,697,213, Jan. 1. A liquid varnish-making ingredient such as an oil mixt. is passed as a continuous stream through a series of containers at regulated temp. and pressure and the app. is arranged for proportionate addn. of a resinous ingredient to the flowing stream. Details of the app. used are described.

Varnish. BAILEY F. WILLIAMSON and WALTER H. REISLER. U. S. 1,699,646, Jan. 22. The rosin content of gum thus is combined with glycerol and a drying oil such as tung oil in a single operation by heating the materials together in a still and passing steam through the heated mixt.

Varnish. Soc. ANON. POUR L'IND. CHIM. A BALE. Swiss 127,534, Feb. 10, 1927. A colored, fast to light varnish contains a dye of the general formula $\text{R}'\text{N}:\text{NR}''$, in which R' is the aromatic nucleus of a negative substituted, unsulfonated diazo compd., and R'' an aromatic amine with the amino group at the 4-position. Thus, the dye obtained by coupling diazotized *p*-nitroaniline and cresidine is dissolved in varnish, giving a scarlet color. An orange-red varnish is produced with nitrocellulose and 4-nitro-4'-aminoazobenzene. Other examples are given. Cf. C. A. 22, 4844.

Manufacture of varnishes, lacquers and insulating enamels. LUCIEN LEVY. Swiss 127,039, June 30, 1927. Varnishes, etc., are made by sulfonating the condensation products of phenols with aliphatic aldehydes and dissolving the sulfonation products in suitable solvents, such as alcs., hydrocarbons, furfural, nitrobenzene, pyridine, mesityl oxide, acetins, or cyclohexanol.

Lacquers. PIETRO ROSSI. Austrian 110,245, Mar. 15, 1928. Lacquers, particularly for leather goods, of the kind comprising an alc. soln. of gum-lac colored with aniline dyes are improved by addn. of Fe_2O_3 . A suitable lacquer comprises 10 parts of gum-lac, 50 parts by wt. of 94-95% alcohol, and 12.5 parts Fe_2O_3 .

Lacquer. WILHELM SCHMIDTING. Fr. 33,071, Feb. 28, 1927. Addn. to 610,863. See Brit. 282,574 (C. A. 22, 3791).

Preparation of permanently clear lacquers. CHEMISCHE FABRIK KURT ALBERT G. M. B. H. Ger. 448,297, June 11, 1925. Permanently clear lacquers containing rosin are obtained by the addition of Li or Cd compds. which are sol. directly or after reaction with other components of the lacquer. The rosin may be present as such, as ester gum or with synthetic resins such as phenol-acetone-formaldehyde or cresol-formaldehyde resins.

Base for nitrocellulose lacquers. ELEKTRIZITÄTSWERK LONZA. Swiss 127,270, Feb. 12, 1927. The binding agent of a base for nitrocellulose lacquers comprises a mixt. of an oil lacquer with a nitrocellulose lacquer, both of which have been prepd. with solvents capable of dissolving dried oils and resins as well as nitrocellulose. An example describes the incorporation with such a lacquer mixt. of CaCO_3 , ZnO and lithophone.

Synthetic resins. BAKELITE G. M. B. H. Ger. 468,391, May 20, 1925. Synthetic resins sol. in fatty oils are prepd. by heating above their m. p. the cryst. products obtained by condensing β -naphthol with CH_2O or its polymers in presence or absence of an acid condensing agent. The cryst. products may be heated while dissolved in fatty oils and the solns. used as varnishes or lacquers. Cf. C. A. 23, 293.

Synthetic resins. KUNSTHARZFABRIK F. POLLAK GES. Brit. 290,963, May 21, 1927. Colloidal solns. of phenol-aldehyde resins obtained as described in Brit. 267,901 (C. A. 22, 1244) are freed from water, as by distn., *in vacuo*, or with a large surface or with the addition of solvents such as glycerol, so that final hardened products are obtained which are transparent or opalescent. Glass-clear products may be obtained by use of a suitable acid for neutralizing the alk. condensing agent. Various details and examples are given, among which are the use of piperidine as condensing agent followed by use of HCl for neutralizing and use of KOH as condensing agent with neutralization by lactic or phthalic acid.

Purifying phenol-formaldehyde resins. FRITZ SEEBACH (to Bakelite G. m. b. H.). U. S. 1,697,885, Jan. 8. In purifying fusible sol. phenol-aldehyde condensation products, the uncombined phenols and by-products are combined with oxides or hydroxides of Ca, Mg, Al, Cu, Zn or Ni or other metal compds. "higher than the alkali metals" which form sol. compds. with the phenols and by-products, forming by thorough mixing a colloidal soln. and pptg. the resins by means of water. Cf. C. A. 22, 4262.

Condensation products of methylol compounds of ureas. MARTIN LUTHER and CLAUS HEUCK (to I. G. Farbenind. A.-G.). U. S. 1,699,245, Jan. 15. Cryst. compds. sol. in usual lacquer solvents are obtainable by condensing a methylol compd. of urea in an alc. such as MeOH or EtOH with the aid of acid condensing agents under "mild conditions" and stopping the condensation instantly after all the initial material is dissolved and cooling the reaction mixt. Cf. C. A. 22, 3056.

Phenolic condensation products. ARCHIE J. WEITH (to Bakelite Corp.) U. S. 1,699,727, Jan. 22. A preformed phenol-methylene resin of the fusible type is mixed with a phenolic material and with sufficient CH_2 -contg. substance such as CH_2O to provide a higher ratio of CH_2 to phenol than existed in the fusible resin; the resulting mixt. may be heated to obtain an infusible product.

Derivatives of condensation products of aldehydes and phenols. HANS BUCHERER. U. S. 1,697,713, Jan. 1. An alkali-sol. resinous condensation product of cresol or other monohydric phenolic compd. and an aldehyde such as CH_2O is caused to react with an org. halogen compd., e. g., acetyl chloride, the halogen of which can combine with the H of the phenolic groups of the condensation product, in order to form products sol. in ordinary org. varnish solvents.

Electrical heating apparatus for metal objects to be enameled or lacquered. HUNDT & WASSER G. M. B. H. Ger. 468,597, Jan. 19, 1927. Structural features.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Absorption spectra and fluorescence of fats. W. SPROESSER. *Chem. Umschau Fette, Oele, Wachse, Harze* 35, 325-7(1928).—An attempt to detect foreign fats and extd. cacao butter in pressed cacao butter by means of absorption spectra in the ultra-violet region using 5% CHCl_3 solns. failed because the differences were not great enough. S. enlarges upon the possibility of a quant. method by applying Lambert's law of absorption coeffs. to the fluorescence produced by the analytical quartz lamp for ultra-violet light and by measuring the intensity of the emitted fluorescence with Pulfrich's step-photometer. The color of the fluorescence might also be detd. quant. by means of color filters and a procedure is suggested.

P. ESCHER

Fat determination in cacao products. W. LANGE. *Chem.-Ztg.* 52, 1006(1928).—L. points out the similarity between the fat detn. method of Heiduschka and Muth (*C. A.* 23, 1002 and the method described by himself (*C. A.* 10, 941)). A. HEIDUSCHKA AND F. MUTH in their reply to this statement assert that there exists an essential difference.

P. ESCHER

Coloration of fats by the alcoholic extract of *Daucus carota*. PIERRE GALESESCO AND SERBAN BRATIANO. *Compt. rend. soc. biol.* 99, 1460-1(1928).—The constitutive and degenerative fats, as well as the lipoids, are colored a golden-yellow with outline sharply limited by the alc. ext. of *Daucus carota*.

L. W. RIGGS

The gelling of fatty oils. JOHANNES SCHEIBER. *Kolloid Z.* 46, 337-45(1928).—The fatty oils are classified according to drying action into the following groups: wood oil, which dries rapidly with formation of a film; linseed oil, which dries to a transparent, non-tacky film; poppy oil, which dries to a transparent, tacky film; and olive oil, which does not dry. Formulas for these different classes are given. Autoxidation plays an important part in gelling. The "dry point" of drying oils is approx. at the max. on the drying curves. Light and heat accelerate the drying of fatty oils. Differences in action of driers and antioxidants are discussed. The effect of polymerization on gellation is influenced by added materials. By direct heating all fatty oils including olive oil may be gelled by a process of polymerization. Certain catalytic agents (AlCl_3) promote gelling. Apparently the power to gel is not natural but an induced property of the fatty oils.

L. F. MAREK

Simplification of oil-testing processes. M. FRIEDEBACH. *Chem.-Ztg.* 52, 964-6(1928).—A discussion of app. and methods of oil-testing recently recommended, with the conclusion that simpler processes are more desirable and that uniformity in technic must be had to get concordant results.

W. C. EBAUGH

Determination of iodine values (of oils) by Hanus' method. M. WIERNIK. *Farben Ztg.* 33, 1973(1928).—Linseed and Chinese wood oils have been found to give different I values by the Hübl-Waller and Hanus methods, the latter usually being much higher. Polymerized oils show bigger deviations than unpolymersed oils.

B. C. A.

The validity of the Hagen-Poiseuille equation for vegetable oils. PAVEL SLANSKY AND LUDWIG KÖHLER. *Kolloid Z.* 46, 128-36(1928).—A capillary viscometer was constructed that is particularly well suited for the investigation of the flow of highly viscous liquids at low rates of shear. Linseed, hempseed, soy-bean, sesame, rape, castor, olive and peanut oils were found to deviate from the Hagen-Poiseuille equation at low rates of flow. No difference was found in the flow characteristics of drying and non-drying oils. A 2-phase structure for the vegetable oils is suggested. W. OSTWALD, V. TRAKAS AND R. KÖHLER. *Ibid* 136-44.—Pure mineral oils show no structure viscosity at ordinary rates of flow. Purified vegetable oils show little or no plasticity at room temp. but the effect is marked at 5-7°. Structure viscosity is also found in partially polymerized vegetable oils and in com. mixts. of mineral and vegetable oils. The relation between the radius of the capillary used in the viscometer and the detection of plasticity is discussed.

J. G. McNALLY

Jaboty kernel oil. L. MARGAILLAN. *Ann. Musée Colonial Marseille* 3, No. 3, 37-8(1925).—Jaboty kernels (Brazil) contain water 5.7, ash 4, protein 7.9, oil 53.7, cellulose 12.4, N-free ext. 10.3%. The oil m. 45°, f. 36°, n_D^{20} 1.4553, sapon. value 228, I value 23.1, Reichert-Meissl value 1.3, acetyl value 32, unsaponifiable matter 1.6%, resin 3%. The insol. fatty acids (94.3%) have f. p. 35.1°, mean mol. wt. 250, and contain liquid acids 25%, stearic acid 3.4%, palmitic acid 43.6%, myristic acid 28%.

B. C. A.

Pracaxy and owala kernels and their oils. L. MARGAILLAN, A. DUPUIS AND J. ROSELLO. *Ann. Musée Colonial Marseille* 3, 23-8(1925).—Pracaxy (pracachy) kernels,

from *Pentaclethra filamentosa* (Brazil), contain water 10.6, ash 1.4, protein 14.4, fat and resin 48.3, cellulose 4.2, and N-free ext. 21.1%. The yellow, slightly bitter fat m. 28°, n_D^{40} 1.4561, sapon. value 182, acid value 3.6, I value 67.3, Reichert-Meissl value 1.2, acetyl value 54.2, resin content (mol. wt. 470) 0.7%. Owala kernels, from *P. macrophylla* (Congo), contain water 8.5, ash 2.1, protein 25, fat 41, cellulose 5, and N-free ext. 18.4%. The oil m. 24°, f. 23–10°, n_D^{40} 1.4682, d_4^{20} 0.902, sapon. value 181, acid value 3.7, I value 98.9, Reichert-Meissl value 1.27, acetyl value 0, resin 0.5%. The av. mol. wt. of the fatty acids was 309. B. C. A.

Extraction of olive oil. ANTONIN ROLLET. *Mat. grasses* 20, 8364–7(1928).—A description of the Acapulco app. working method, its value and the probable cost of installation and operation. P. THOMASSET

Carbon disulfide and the Spanish olive-oil industry. J. ARTHUR CADDICK. *Chem. Age* (London) 19, 536–7(1928).—The extn. of olive oil by CS₂ and the manuf. of CS₂ are described. E. SCHERUBEL

Oil from *Aleurites montana*. C. D. V. GEORGI AND GUNN L. THIE. *Malayan Agr. J.* 16, 296–8(1928).—The oil content of the whole seed is 22.8%, and of the kernel 43.2%. The consts. of the oil are: d_{15}^{20} 0.939, n_D^{20} 1.5098, sapon. no. 195.5, I no. 160.3, unsapon. 0.6%, titer 36.8°, mean mol. wt. of fatty acids 298.4, neutralization value of fatty acids 188.0, I no. of fatty acids 164.7. The consts. are similar to those of Chinese wood oil, except for a small diff. in I no.; but there are marked differences from candlenut oil. E. SCHERUBEL

Physical properties of pure triglycerides. R. B. JOGLEKAR AND H. E. WATSON. *J. Soc. Chem. Ind.* 47, 365–8T(1928).—The values of Scheij have been confirmed, the main diff. being in the densities of palmitin and stearin. The m. p. and n afford little criterion as to purity. Viscosity is the most sensitive test for impurity, but requires a very careful temp. adjustment. Tables show solidifying point, n , sp. gr., viscosity and surface tension of triglycerides at different temps. The sp. gr., viscosity and surface tension of palmitin-stearin mixts. present no unusual features. E. SCHERUBEL

Fish and marine animal oils. H. M. LANGTON. *Chemistry and Ind.* 47, 1334–43 (1928).—This paper discusses the fish-oil industry, the various oils produced, equipment used, and contributions of various workers regarding the compn. of the oils. E. SCHERUBEL

Liver oil of *Paralithodes camtschatica*. MITSUMARU TSUJIMOTO. Inst. Tokyo Ind. Research. *Bull. Tokyo Inst. Ind. Research* [3], 23, 25–41(1928).—The oil was freed from H₂O by heating it at 110°, and filtering, d_4^{15} 0.9456, acid value 97.9, sapon. value 155.6, I, value (Wijs method) 63.6, n_D^{20} 1.4750, unsapon. matter 1.39%. It has a characteristic bad odor. The fatty acid contains an acid of more than C₁₁. The cholesterol detd. by the digitonin method is 22.67%; 1.45% for the original sample. By treating 1000 g. of the sample by the usual method, 58 g. of unsapon. matter was obtained. This was dissolved in MeOH, cooled with ice and NaCl, and the sepd. crystals (A) (26 g., contg. a small portion of solvent) filtered off. The mother liquor (B) resulting from the removal of A is a viscous liquid which is believed to contain the so-called liver-resin. The crystals obtained (3–2 g.) by crystg. from MeOH and by acetylating it is near the Ac compd., C₂₁H₄₂O(COCH₃)₂ of batyl alc. When hydrolyzed, the latter forms batyl alc. When (B) is acetylated, fractionated and the distillate is sapond. cholesterol-batyl alc. results. The liquid remaining after removing this is *cerakyl alc.*, C₂₁H₄₂O₂. By sepg. the lower-boiling up to b_p 195° acetylation product of (B) a new unsatd. alc. with the probable formula C₁₁H₂₀O₂ is obtained, which is to be more closely examd. later. This liver oil contains besides a resinous substance which can not be distd., probably also *kimyl alc.* and another unsatd. alc. K. SOMREVA

Effect of temperature change on the color of red and yellow Lovibond glasses. DRANE B. JUDD. *Bur. Standards J. Research* 1, 859–66(1928); cf. C. A. 22, 4265.—The relative spectral transmission at 12 wave lengths of Lovibond glasses 35Y and 7.2R were detd. at 15° and at 40° by means of the Koenig-Martens spectrophotometer (McNicholas, C. A. 23, 333) equipped with a thermostat for control of the temp. of the sample. The effect of increasing the temp. of the glasses is to shift the curve of spectral transmission somewhat toward the red. Both glasses show this sort of shift; the shift for the 35Y glass is about 4 or 5 times as great as that for the 7.2R glass. Thus the 35Y glass or the combination of 35Y + 7.2R must become more reddish on being heated. Heating either the 35Y or the 35Y + 7.2R filter 25° above normal is nearly equiv. to adding 0.2 Lovibond red. This difference is almost negligible in the color grading of cottonseed oil. Preliminary work on 2 samples of cottonseed oil shows that the oil changes in color with change in temp. even less than the glasses do. A. J. MONACK

Detergent action of soap. F. H. RHODES AND S. W. BRAINARD. *Ind. Eng. Chem.* 21, 60-8(1929).—A method is described which measures detergent power directly under conditions of laundry practice. Variations in temp. between 20° and 60° have little effect. The max. effect was produced in 7.5 mins. Increasing the concn. of soap above 0.25% produces little change in detergent effect. Solns. contg. 0.05 and 0.1% of soap remove about the same amt. of dirt in 5 washings as do more concd. solns. but solns. of 0.01% soap are less efficient.

E. SCHERUBEL

Deterioration of some silk-scouring soaps on storing. The so-called "ase" or sweat of soaps. R. TSUNOKAE. *J. Soc. Dyers Colourists* 44, 377-9(1928).—According to Tsujimoto the discoloration of soap is due to the oxidation of the unsatd. aliphatic acids. No relation was proved between the moisture content of the soap and the "ase" produced. The greater the quantity of petrolic ether ext. of the soap the greater the production of "ase." The greater the quantity of "ase" in the soap the less its degree of hydrolysis and the less its scouring power on silk. "ase" is produced on the surface of soaps even in sealed sample bottles. The color varies from light yellow to dark brown. At first "ase" appears on the surface, but as it increases it flows and forms a layer at the bottom of the sample bottle. The production of "ase" is related to air and light. Moisture in soap and in "ase" from that soap was 23.07 and 24.42%, resp., petrolic ether ext. 5.51 and 6.99%, resp. The soap in "ase" contained over 50% of oxidized aliphatic acids, whereas soaps which did not produce much "ase" contained 5.6 to 12.9%. The silk-degumming power of non-oxidized aliphatic acid soap was greater than that of oxidized soaps; hence the production of "ase" marks the deterioration of soap.

L. W. RIGGS

Oils for wool (MULLIN) 25. Glycerides of fatty acids (HEIDUSCHKA, SCHUSTER) 10. Ricinic acid (SUNDER) 10. Chemical constitution of tetradecenic acid obtained from *Tetradenia glanca* (TSUJIMOTO) 10. Chemical constitution of iwashi acid (TSUJIMOTO) 10. Heat-exchange and pumping apparatus for heating and pumping oils (U. S. pat. 1,697,605) 1. Apparatus for separating oil and water by gravity (U. S. pats. 1,698,002; 1,698,067 and Brit. pat. 291,123) 1. Producing products such as heptaldehyde from heavy vegetable oils (U. S. pat. 1,697,337) 10. Me formate or similar formates as solvents in purifying oils (Brit. pat. 291,817) 13.

BAUER, K. H.: *Chemische Technologie der Fette und Öle*. Pareys Bücherei für chemische Technologie. Berlin: P. Parey. 420 pp. R. M. 24.

Treating fatty substances. VIKTOR A. R. FAURSKOV. Fr. 642,172, Oct. 11, 1927. Fatty substances are passed with a whirling motion between cylinders for the prepn. of substances such as margarine.

Forming glycerol esters from free fatty acids. METALLBANK UND METALLURGISCHE GES. A.-G. Brit. 291,767, June 8, 1927. Fatty acids or oils or fats contg. them are heated with glycerol *in vacuo*, in an app. which is described and in which the pressure may be reduced to 2 mm. by an ejector placed between the reaction vessel and a condenser.

Apparatus for distilling fatty acids with steam. METALLBANK UND METALLURGISCHE GES. A.-G. Brit. 291,093, May 27, 1927. The steam used may be passed through a compressor to raise its temp.

Bleaching and deodorizing fats, oils and fatty acids. FRITZ GRUBER. Austrian 109,719, Jan. 15, 1928. The fats, etc., are treated with com. H_2O_2 soln. and with a peroxide insol. or sparingly sol. in water, such as BaO_2 .

Oil and fat treatment. HEINRICH BERSYCH (to H. Th. Böhme A.-G.). Can. 285,879, Dec. 25, 1928. Preps. or compds. suitable for use in the textile, leather and pharmaceutical industries are produced by mixing a phosphoric acid compd. with a fatty substance to be treated, maintaining temp. control during the reaction, washing the reaction product with water, and sepg. the wash water from the product.

Treatment of oils or fats or mixtures of same or fatty acids for the production of sulfuric acid compounds. HANS STOCKHAUSEN, FRITZ SCHLOTTERBECK, CONRAD CREMER AND ARNULF HECKING. Can. 285,772, Dec. 25, 1928. The process consists in sulfonating the said oils, etc. with more than 30% H_2SO_4 , which is rapidly added, and simultaneously cooling the mixt. intensively so that the temp. does not exceed 10-15°, washing the mixt. immediately and neutralizing in the usual way. The products are useful as *wetting out agents*.

Sulfonated oils and fats. CARL DREYFUS. Fr. 636,586, June 25, 1927.

fonated oils and fats contg. a large proportion of H_2SO_4 in org. combination are prepd. by the action of $AcOH$ and SO_3 , or $AcOH$ and chlorosulfonic acid in simple or multiple equimol. proportions. $AcOH$ may be replaced by other low aliphatic acids such as formic, propionic, butyric or lactic acid, or the anhydrides or chlorides of low aliphatic acids may be used. Examples are given of the sulfonation of olive oil, ricinoleic acid, olein and ricin oil. Cf. *C. A.* 23, 536.

Extracting oils from animal and vegetable materials. JOHN W. BECKMAN. U. S. 1,698,294, Jan. 8. Coconut copra or other oil-bearing materials are macerated with water and inoculated with lactic acid-producing bacteria and maintained at a temp. to promote bacterial action and a reagent such as $MgCO_3$ is added to maintain the mixt. approx. neutral as the bacterial action progresses; oil thus released from the cells is then sepd. by gravity and decantation or in other suitable manner.

Extraction of oil, gelatinous water and solid substances from animal and vegetable matter. KRISTIAN HOLTER and SVERRE THUNE. Ger. 469,020, Apr. 16, 1925. See *Can.* 274,972 (*C. A.* 22, 1246).

Turkey red oil substitutes. H. TH. BÖHME AKTIENGESSELLSCHAFT. Fr. 642,392, Oct. 10, 1927. Oil and fats are treated with P_2O_5 , acetylphosphoric acid or mixts of H_3PO_4 with Ac_2O or $AcCl$. Examples are given of the treatment of castor oil and oleic acid. The products may replace Turkey red oil in the textile and leather industry, as emulsifying agents or for making pharmaceutical products.

Treatment of castor oil. ALEXANDER SCHWARCMAN (to Spencer Kellogg & Sons, Inc.). Can. 285,743, Dec. 18, 1928. Castor oil is heated to a high temp. (between 550° and 575° F.) *in vacuo* to produce polymerization and improve the miscibility of the oil with mineral lubricating oils; a slow flow of CO_2 or gases contg. the same, is usually, but not invariably, passed through the oil during heating. The action is usually carried on until the miscibility of the castor oil with alc. disappears, and the miscibility of the castor oil with mineral oils, including lubricating oil, increases.

Treatment of fish. GEORGE R. HENSHALL. Can. 285,632, Dec. 18, 1928. Fish or fish offal is cut into small pieces and treated with a soln. of $Fe_2(SO_4)_3$ (frequently in combination with $Al_2(SO_4)_3$) and the mass is left to pickle for 2-24 hrs. This releases all the oil. When the pickling is complete the material is put through a helical conveyor immersed in boiling water to ext. the oil. Oil, fish meal and fertilizers are produced.

Rotating shaker for rapid saponification. CYPRIEN GILLET. Fr. 641,194, Mar. 2, 1927.

Soap. PAUL SERRE. Fr. 641,359, Sept. 23, 1927. Cakes of soap pulp are prevented from becoming hard by dipping them in melted paraffin to obtain a thin protecting layer.

Soap. GUBSER-KNOCH. Swiss 127,536, Jan. 27, 1927. Soap is prepd from neutral curd fat and alkali by heating the fat with concd. alkali lve till the water is almost completely evapd.

Powdered soaps. D. R. LAMONT (to Industrial Spray-drying Corp.). Brit. 291,041, May 25, 1927. A heated, freely flowing soap soln. is sprayed in fine drops into a current of heated gas (such as combustion gases from an oil burner, dild with air) to produce hollow globular particles.

Cleansing agent. KARL MAIER. Swiss 127,537, Aug. 13, 1927. A cleansing agent for the hands contains soap paste, an alk. Na salt and sawdust.

Recovering glycerol from materials containing proteins. JOHANNES ALTENBURG. Ger. 467,350, Mar. 12, 1927. Materials containing glycerol mixed with proteins, such as hectograph masses or printing cylinders, are brought into solution in hot water, treated with formaldehyde to render the protein insol. and the product is ground and extd. with water. The resulting glycerol soln. is rectified. The hardened protein may be used as a fertilizer. Cf. *C. A.* 23, 610.

28—SUGAR, STARCH AND GUMS

S. W. ZERBAN

Measuring the hydrogen ion concentration of sugar products. N. LOGINOV. S.-Kh. Inst. of Voronezh. *Bull. Sakharotrests (Bull. Sugar Trust)* 49, No. 5, 40-4 (1927).—This study was undertaken for the purpose of introducing colorimetric or elec. methods of p_H detn. in the chem. control of beet-sugar factories; the old titration method does not give satisfactory results, and only p_H can be used to det. the real acidity of the

acts. The meaning of p_H is explained and the indicator method is described. s. have shown that diln. with H_2O has no effect on the p_H of molasses and only ght one on that of massecuite. This proves that molasses is a good buffer soln. solns. contg. sugar have a lower p_H than the same solns. free from sugar. This e to the formation of monosucrate of Ca, of the formula $(C_{12}H_{22}O_{11}Ca).(OH)'$. acid disocn. const. of sucrose in H_2O soln. is 2.4×10^{-13} at 25° . V. E. B.

Determination of moisture in sugar sirups. E. W. RICE. *Ind. Eng. Chem., Analytical Ed.* 1, 31-2(1929).—The definition of "moisture" is merely arbitrary, because ent salts lose water of crystn. at different temps., and because certain non-sugars wt. at a temp. as low as 70° . Const. wt. can be reached by placing the sample 8 hrs. in a Hempel desiccator over H_2SO_4 at a pressure of 1 inch. No further loss .. was found after 10 days. It is undoubtedly wise to accept this method as stand-

The present official A. O. A. C. method is cumbersome, and it does not yield a l. wt. The original Bidwell and Sterling method (C. A. 19, 620) also gives unre- results if the % of invert sugar is high, even when an oil bath is substituted for id bath. The addn. of 10 g. Na oxalate to the mixt. of product and toluene increased listn. rate and prevented blackening. The most satisfactory results were obtained lacing approx. 5 g. of Filter-Cel in the distn. flask, and weighing 15 g. of sirup into psule formed from a piece of thin waxed paper resting in a 15-cc. Gooch crucible. weighed capsule is dropped into the flask, and 5 more g. of Filter-Cel added. The r is carried out according to Bidwell and Sterling. The results obtained with 3 distn. agreed closely with those of the official method. F. W. ZERBAN

The determination of sucrose and starch sirup. J. D. FILIPPO. *Chem. Weekblad* 57:6 9(1928).—In several sirups of known compn. F. has detd. the amt. of water-starch sirup and invert sugar. For inversion it was found that a 3.5 N HCl soln. the right strength to use. In a mixt. of starch sirup and invert sugar sirup, the water-starch sirup can be found by taking a 20% soln., treating 25 cc. with 50 cc. 3.5 N , and from the rotation in a 4-dm. tube the total amt. of glucose can be calcd. In ther portion the amt. of fructose is detd. by the Kolthoff-Kruisheer method. The rence between the 2 findings gives the amt. of water-free starch sirup. J. C. J.

The reaction between amino acids and glucose. J. A. AMBLER. *Ind. Eng. Chem.* 50(1929).—This preliminary study has shown that the course of the reaction end. entirely on conditions of concn., temp., and time of heating. At the b. p. ugh as 10 mols. of glucose may be destroyed per mol. of amino acid, but lowering of temp. reduces the effect. In this reaction compds. of progressive complexity, beg- ing to the general class of melanoidins, are formed by dehydroxylation. CO_2 is evolved, except at high concns., but if any gas be formed in molasses or sirups through er reactions, the melanoidins greatly increase the tendency to froth. They also ease the color of the products. F. W. ZERBAN

Notes on the bleaching of off-color crystals. J. P. OGILVIE AND R. G. W. FARNELL. *ern Sugar. J.* 30, 92-3(1929).—A great deal of work has been done on the bleach- of sirups, and juices with SO_2 , ozone, Cl, and other gases, but apparently little has n done on the bleaching effect of these substances upon sugar crystals. Cane (Mauri- nsultation white) and beet after-product (washed crystals), both having a decidedly low color, were treated with Cl, SO_2 , ozone, NO and NO_2 , at varying temps., and some tests in the presence of superheated steam. The results showed considerable provement was obtained with Cl, and ozone on the beet sugar, but none of the gases ed produced any noteworthy improvement in the cane sugar. The explanation of is to be attributed to the presence of insol. tannin matter, which constitutes the lor of the cane product, and which is not affected by the treatment as above described. W. L. OWEN

Pokkahbong and twisted top diseases of cane. C. N. PRIODE. *Facts About* 23, 1244(1928).—P. describes the diseases briefly. M. J. PROFFITT

Maceration practice. W. R. MCALLEP. *Facts About Sugar* 23, 1240-3(1928).— reviews the results obtained with various methods of juice extrn. from cane and as- ibes the defects of ordinary mills to deficient maceration and the failure of the diffu- on methods to insufficient drying of the bagasse. He suggests adopting the practice removing about 80% of the juice in 2 high-pressure mills with ordinary maceration, treatment of the resulting bagasse in a continuous diffuser with systematic circulation f the maceration liquid, and, finally, drying the extd. bagasse by passing it through or 2 high-pressure mills of standard type. M. J. PROFFITT

Carbonation according to Pshenichka. YA. B. FEIGIN. *Bull. Sakharotresta* Bull. Sugar Trust) No. 11, (55), 15-8(1927).—Good filtration work in the Shaluginiskii ugar factory is due to the use of the Pshenichka process. Milk of lime (0.2 to 0.3%

on the total wt. of beets) is mixed with diffusion juice which remains very slightly acid. In the same tank unfiltered juice from the 1st carbonation (5-15% on total wt. of beets) is added. The mixt. is heated to 90°, pumped to defecators, and 2% CaO added. After 20 mins. the juice is sent to the 1st carbonation. CaO added to diffusion juice and CaCO₃ in carbonation juices adsorbs colloidal non-sugars and ppts. coagulated albumin. The filter cakes are hard, granular and easily washed. Purification is high, 81-82%.

V. E. BAIKOW

The analysis of unchopped bagasse. V. KHAINOVSKY. *Arch. Suikerind.* 36, 111, *Mededel. Proefstat. Java Suikerind.* 843-916(1928).—In this paper are discussed all expts. on the sampling and analysis of bagasse made at sugar mills and at the expt. station, which led to the new method of analysis described previously (*C. A.* 21, 3481). Chopping bagasse takes too much time; the polarization is changed by inversion, and the moisture by drying out. Possible errors of a chem., phys., mech. and personal nature are discussed. Addn. of NaHCO₃ when boiling bagasse is advised, because the acidity of bagasse from stored or diseased cane is too high and causes inversion. Lead subacetate should be added after boiling to avoid the soln. of non-sugars which affect the polarization. If the filtrate is not clear enough for correct reading, Filter-Cel should be used. Comparative tests showed that polarizations of bagasse made with the new app. are accurate to 0.1%, if the boiling time is 1 hr. and the circulation in the app. is sufficient. Comparative tests on the moisture of chopped and unchopped bagasse showed that moisture is lost during chopping. The drying must be done in a specially constructed oven where a circulation of hot air is possible. Expts. showed that a temp. of 130° is permissible and 1 hr. is sufficient for complete drying. The limits of error in the moisture detn. with the new oven amount to 1% on bagasse. P. R. P.

The production and refining of Indian gur or jaggery. J. T. J. CROOKS. *Intern. Sugar J.* 30, 189-92(1929).—The cane from which jaggery is made is of the thin hard-rind type of very high fiber content, and the extn. of the juice by the primitive mills employed, is very inefficient. The juice is evapd. in open pans, and the inversion of the sucrose is very high. Losses from inversion are accentuated by the prejudice of the natives towards the use of lime in clarification. Jaggery made with lime always brings lower prices in the market. The juice is evapd. to a stage where it will solidify on cooling. It is then cooled and rolled into balls known as belli gur or poured into holes in the ground that have been previously prepd. for that purpose. The latter method produces a sugar known as chunkie gur. The refining of gur is carried out both in modern refineries and by primitive native methods. Although the sugar from the refineries has a polarization of 98.5 as compared with 94.5 for the product from the native refineries, the latter brings a much better price in the market. The colloid content of jaggery is very high, and the yield is very much affected by it. W. L. O.

Inulin. VI. H. PRINGSHEIM AND I. FELLNER. *Univ. Berlin. Ann.* 462, 231-9 (1928); cf. *C. A.* 20, 3017.—Results of mol. wt. detns. of inulin in AcOH, PhOH and H₂O are given as well as of the sapon. products of inulin after heating at 250°, 260° and 290°. The enzymic degradation of inulin was also followed for 192 hrs.

C. J. WEST

Röntgen diagram of native starch. ST. V. NÁRAY-SZABÓ. Kaiser Wilhelm Institut für Faserstoffchemie. *Ann.* 465, 299-304(1928).—The Debye-Scherrer method of x-ray analysis has been applied to starch from different sources. A Cu-K anticathode is used and the starch is contained in a glass capillary. Starches may be divided into the potato group (from potato, *Curcuma angustifolia*, *Canna indica* and *C. edulis*, *Musa paradisica*, *Dioscorea alata*, *Arracalia esculenta*, *Jatropha manihot* and *Araucaria brasiliensis*) and the rice group (from rice, wheat, millet, *Maranta arundinacea*, *Ipomoea tjalappa*, *Arum esculentum* and *Balata edulis*). The former are characterized by a strongly marked ring 1 (not observed by Sponser or by Otto), from which the distance between the planes of the crystal lattice is calcd. as 16.0 Å. U.; there is a 2nd strong interference at ring 5. In the rice group ring 1 is absent and rings 5 and 8 are present. The variations in strength of the rings from the 2 groups cannot be due to contamination or deformation; the amt. of amylopectin has no influence on the diagrams and swelling by absorption of H₂O has only normal effects. It is therefore suggested that the parameters of the unit cell (of which the vol. is calcd. to be 2.524×10^{-21} cm., i. e., 16 C-H₂O₂ groups) vary, through either phys. or chem. differences between the different starches.

Centrifuge, especially for sugar manufacture. FRANZ MARCZINEK. Ger. 468,619, Mar. 29, 1927. Structural features.

Glucose from starch. CORN PRODUCTS REFINING CO. Brit. 291,991, Aug. 19, 1927. See Fr. 638,956 (C. A. 23, 541).

Purification of starch. W. H. UHLAND G. M. B. H. Fr. 641,277, Sept. 21, 1927. To remove albumins, crude starch is treated with dil. solns. of hypochlorites, contg. at least 1.6 parts of active Cl for each part of albumin.

29—LEATHER AND GLUE

ALLEN ROGERS

Tanning leather with badan extract. A. SMETKIN AND A. PISSARENKO. *Collegium* 1928, 481-7.—From badan ext. alone (see following abstract) a satisfactory sole leather was prepared. A brief description of the method of tanning is given. Penetration and swelling were best at pH 3-4. With increasing concn., the viscosity of badan ext. increased much more rapidly than that of oak wood or quebracho exts. This and the slow diffusion into skin indicate that badan ext. has a low degree of dispersion. It is not, however, as readily salted out as quebracho probably because it contains gum-like nontannins. I. D. CLARKE

Factory experiments on the preparation of purified tannin extracts from badad by the Smetkin-Yakimov method. A. SMETKIN AND P. YAKIMOV. *Collegium* 1928, 477-80; C. A. 22, 4002.—Ground roots contg. 20.17% tannin and 20.66% nontannin were used. Instead of H_2O at 4°, it was necessary to use sea water at 23° for the cold- H_2O leach. This ext., 93.6 cu. m. from 650 kg. of roots, contained 6.28 kg. of nontannin and 2.75 kg. of tannin per cu. m. The ext. from the 95° leach., after concn. to 20° Bé. contained 21.60% tannin and 11.44% nontannin. The quality of the ext. from finely ground roots, 3-6 mm. diam. was a little better than that from coarsely ground roots, 6-15 mm. diam. I. D. C.

Some phenomena in vegetable tanning. CESARE SCHIAPARELLI AND GIOVANNI BUSSINO. Lab. Unit. Ital. Tanneries, Turin. *Boll. ufficiale stas. sper. ind. pelli mal. concianti* 6, 259-67 (1928); cf. C. A. 22, 2483.—This is a contribution to the question: Is the process of vegetable tanning truly chem. in nature or not? In the expts., the increase in wt. of 100 parts of dry protein when treated with various tannins was detd. A piece of hide corresponding to 10 g. protein dried at 100° was tanned with tannin purissimum Merck or Kahlbaum, or with oak bark ext. The latter was prepd. by extg. at low or at elevated temp. Twelve g. tannin was used for 10 g. dry protein. In some expts. the solns. were acidified with 1.125 parts of lactic acid for 100 parts of protein. The progress and the end of the tanning were detd. by means of the hydrostatic balance. After the tanning, the sol. substances were eliminated by rinsing the leather for 4-6 hrs. with H_2O at 45-50°. In the expts. with pure tannin, 100 parts of dry protein combined irreversibly with about 70 parts of tannin Kahlbaum and with about 78 parts of tannin Merck. The difference between the quantities of tannin fixed is due to a

difference in chem. compn. One hundred parts of dry protein combined with about 57 parts of oak bark tannin regardless of the temp. of prepn. of the ext. Acidification had only a slight effect on the leather yield. S. and B. conclude that their results favor the conception that vegetable tanning is chem. in nature. G. SCHWOCH

The diosmosis of tannin in presence of mineral salts dissolved in the tannin solutions. ANDREA PONTE. Lab. della S. N. Industrie Conciarie, Corsico (Milan). *Boll. ufficiale staz. sper. ind. pelli mat. concianti* 6, 308-28(1928).—The diosmosis of a pure tannin soln. was compared with that of tannin solns. contg. certain quantities of mineral salts. The former soln. contained 8% tannin, while the latter solns. contained, besides 8% tannin, 1.5 g. mols. of NaCl, Na₂SO₄, NaHSO₄, Na₂SO₃, or NaHSO₃, resp., per 1000 cc. Three hundred cc. of the soln. to be examd. was placed in a dialyzer of special construction and dialyzed against 1200 cc. of distd. H₂O at 25° for 24 hrs.; after that period the process was repeated in the same way. Then the external and internal solns. were analyzed, the latter after being dild. in the ratio 1:50. For the tannin detn., the method of Vigna (*Staz. aper. agr.* 1895, 22) was given preference to that of Löwenthal-Hunt. According to Vigna's method, the tannin was pptd. with an 8% K alum soln. and a slight excess of NH₃. The ppt. was collected on a filter, washed with cold water, redissolved in boiling 25% H₂SO₄ and titrated with indigo and KMnO₄. P. found Vigna's method better suited for his expts. than that of Löwenthal-Hunt because, unlike the latter, it is not much influenced by the tannin concn., provided that the total tannin content ranges between 0.025 and 0.050 g. Furthermore, the tannin can be detd. in presence of bisulfites or sulfite cellulose liquors. In case gallic acid is present, Vigna's method cannot be used. When comparing the diosmosis of tannin solns. with that of solns. of tannin-mineral salts, it was found that NaCl, Na₂SO₄ and NaHSO₄ had no influence on the velocity of the tannin diffusion, no increase in the amt. of the diffusing tannin being noticed. The color of these solns. was orange-brown. In the tannin-NaHSO₃ soln., which was of yellowish green color, the velocity was increased, and it was still greater with the Na₂SO₃-tannin soln., which had a garnet-red color. P. believes that in case of the 2 latter solns. chem. reactions take place giving rise to formation of compds. that are of a character less colloidal than tannin itself. G. S.

The bark of the Siberian larch as a raw material for the preparation of tannin. P. YAKIMOV AND N. VELTISTOVA. *Collegium* 1928, 488 95.—The larch, *Larix decidua* var. *Sibirica*, is abundant in central and eastern Siberia. The quantity of bark is estd. to be 500,000,000 tons. The bark contains 8-18% tannin, 5-9% nontannin and up to 1.4% reducing sugar. There was more tannin in the inner layers than in the other layers of the bark, probably because tannin is removed from the latter by weathering. With increasing distance from the ground the percent of solubles, nontannin and sugar in the bark increased, while the purity of the ext. and thickness of the bark decreased. Diseased trees contained 4-6% tannin. I. D. CLARKE

Synthetic tans. S. R. TROTMAN. *Ind. Chemist* 4, 499 500(1928).—The chem. constitution of the natural tannins is still uncertain, but numerous attempts to synthesize tannin compds. have nevertheless been made, among the earliest being those of Fischer and Freudenberg (1912). The methods of prep. synthetic tans as given in the patent literature from 1913 are briefly outlined for the better-known processes. E. G. R. ARDAGH

Chrome tan. E. STIASNY. *Collegium* 1928, 554 67.—A lecture reviewing the application of Werner's theory to basic Cr salts. Only salts which are semi-colloidal tan. Recent work with Olschansky has shown that the action of soda on Cr salts differs from that of NaOH in that soda gives a violet instead of a green color, the pptn. no with soda is much greater, and the turbidity does not redissolve on aging. With soda, carbonate complexes are formed; these rapidly condense to ol compds. Since part of the soda is used in forming carbonate groups, the basicity is less than calcd. The usual methods of detg. basicity do not give true values, for in hot dil. solns. the carbonate compd. is not stable. The oxidation method (Burton) gives correct values if after adding the excess of NaOH and oxidizing the Cr to chromate with H₂O₂, BaCl₂ is added to ppt. carbonate. Then the excess NaOH can be detd. as usual. I. D. CLARKE

The catalytic effect of some organic substances on the activity of the macerating agents. MAX HOTZ. *Boll. ufficiale staz. sper. ind. pelli mat. concianti* 6, 303 7(1928).—In order to find substances more efficient in activating the enzymes used for macerating hides than are KCN, amino acids and acetaldehyde-cyanohydrin (M. Jacoby, *C. A.* 21, 2000), H. examd. the action of nitriles. Aliphatic and aromatic nitriles of the type RCN have a positive effect, but are of little practical value. More suitable are nitriles of the type RNHCH₂CN (R = aryl), which are easily prepd. according to R. Lepetit's method. PhNHCH₂CN (I) has the disadvantage of being only slightly sol. The

SO_3H , COOH and OH derivs. of I, however, are sol. enough. Thus *p*-cyanomethylaminophenol (II), *p*-cyanomethylaminobenzoic acid (III), the Na salts of *m*- (IV) and *p*-cyanomethylaminophenylsulfonic acid (V), and Na 1,4-cyanomethylaminonaphthylsulfonate (VI) were prepd. II and III slowly decompose in soln., while the solns. of IV, V, and particularly of VI are stable. All 5 nitriles accelerate the action of the macerating enzymes; besides, they exert a favorable influence on the hide by completely eliminating the subcutaneous fat. Very small quantities of the nitriles are required for the effect. V and VI produce a lighter-colored hide than do II and III, the shade of the color produced by the 2 latter nitriles corresponding with the color of the slowly decomposing solns.

G. SCHWOCH

Valuation of cellulose extracts. E. ANACKER. *Collegium* 1928, 495-9.—A complete analysis of a cellulose ext. must include total solubles, ash, affinity for hide, hygroscopicity, acidity, color and odor. Det. the affinity for hide, "tannin," with solns. contg. 10 g., and 20 g. of ext. per l.; the less the difference between the results the greater the affinity. Dry in a desiccator a small amt. of ext., absorbed on a weighed filter paper, then expose it for 3 hrs. to a known humidity and reweigh; the gain in wt. is a measure of the hygroscopicity. The odor of the ext. is not characteristic of the odor it will impart to leather but if a 5° soln. is dialyzed 24 hrs. and the dialyzate is evapd. the odor of the residue is characteristic. The acid no. is the no. of cc. of 0.1 N alkali required to neutralize to phenolphthalein 1 g. of ext.

I. D. CLARKE

The analysis of artificial leather bates. V. KUBELKA. *Collegium* 1928, 604-11.—Casein has been chosen as substrate for detg. the activity of bates because uniform lots having practically identical properties can be supplied. This is more important than similarity to hide substance. Bates have a proteolytic and a peptolytic enzyme. The proteolytic enzyme renders the interfibrillary substance of the hide sol. Any action of the peptolytic enzyme on this sol. matter is of no importance in bating. Therefore the Kubelka-Wagner method (C. A. 20, 3835), which measures decrease in the quantity of substrate, is better than the Schneider-Vleck (C. A. 21, 4090) or a similar method which measures the quantity of decompn. products, especially if the degree of decompn. influences the measurement.

I. D. CLARKE

The action of salt on skin. MAX BERGMANN. *Collegium* 1928, 599-604.—The permeability or no. of cc. of liquid passing through skin in 15 mins. under a pressure of 1 atm. was measured with H_2O (I), salt solns. (II) and again with H_2O (III). A calf skin unharmed by sweating was used; the salt solns. were N/160 to N/2.5. II was always less than I or III. III was less than I except after N/160 salt soln., when it was 150% of I. Concd. salt solns. caused a falling of the skin and greatly decreased porosity. With N/2.5 salt soln. II was 2.3% of I and III was 8.8% of I.

I. D. CLARKE

Hide defects. I. Salt stains. FRITZ SEATHER. Kaiser Wilhelm Inst. für Lederforschung, Dresden. *Collegium* 1928, 567-99.—The following defects are usually classed as salt stains: (1) salt pricks caused by crystn. of salt in the grain, (2) blue, red or lilac colorations of the flesh caused by chromogenic bacteria, (3) brick- or carmine red heat stains on the flesh which often cause loose hair and grain damage, (4) lemon yellow or orange-brown specks, 4-8 mm. in diam. scattered over the flesh, (5) bright yellow or orange spots, 3-5 mm. in diam. close together, forming large bands across the flesh. Only the last class of stains was investigated. These do not cause hair slip but can be found on the grain after shaving the hair. There is often damage around the hair roots. Holes may be formed within the skin. After liming with sulfide, large brownish gray stains are found. The damaged hide fibers do not show double refraction; they are not swelled by NaOH and their affinity for dye is different from that of unchanged skin. Several pure cultures of bacteria were isolated from stains. The following are described; *B. mesentericus*, *Staphylococcus pyogenes aureus*, *sarcinae*, *Corynebacterium* and 2 types of *Actinomyces*. Cultures of these were grown on agar medium contg. NaCl. 1 or 2% NaCl did not check and sometimes stimulated growth; 8% NaCl checked growth but did not kill; 4-8% NaCl contg. 5% Na_2CO_3 decreased growth greatly. In stained hide as compared to unstained, Fe was 4-15 times as high, P_2O_5 was 1.5-10.9 times as high and SO_3 and Ca were unmistakably higher. The P_2O_5 must be set free from nucleic acids by bacteria. Attempts to liberate Fe from blood by bacterial action were unsuccessful. Hide inoculated with the pure cultures of bacteria developed salt stains. Blood on the hide also caused stains; if the blood was inoculated with the isolated bacteria the stains were more pronounced. Solns. of $(\text{NH}_4)_2\text{PO}_4$ or CaCl_2 caused stains similar to those of class 4. The methods of prevention suggested are: clean or keep the hides free from dirt, blood, etc.; salt soon after flaying; use 15-20% salt and cover all parts of the hide; add an antiseptic material such as 5% soda to the salt.

I. D. CLARKE

Characteristics of commercial gelatin and glue. M. RÜDIGER AND E. MAYR. *Kolloid-Z.* 46, 81-9(1928).—Chem. analysis of com. gelatin and glue was found to be an unsatisfactory method of evaluating material to be used in *wine clarification*. The degree of degradation of the protein detts. the suitability of the stock for this purpose and this is best indicated by tannin pptn., viscosity and change in viscosity with time.

J. G. McNALLY

The significance of mechanical wood joint tests for the selection of woodworking glues. T. R. TRUAX, F. L. BROWNE AND DON BROUSE. U. S. Forest Products Lab. *Ind. Eng. Chem.* 21, 74-9(1929).—All kinds and grades of glues used in woodworking make *good joints* (as distinguished from the 3 types of poor joints, chilled, starved, and dried joints, resp.) provided that the proper gluing conditions are followed, but the conditions giving good joints with animal glue of low grade, for example, produce poor joints with glue of high grade and *vice versa*. Furthermore, good joints with all glues in common use are as strong as the wood joined. In selecting glue, therefore, the woodworker is not concerned about its "strength," but he does want to know the gluing conditions under which it will make good joints. Measurements of such properties as viscosity and jelly strength give him that information, but mechanical tests of wood joints made under an arbitrary set of gluing conditions do not. Mechanical wood joint tests find their place in research into gluing technic.

F. L. BROWNE

The nature of adhesion between glue and wood. F. L. BROWNE AND DON BROUSE. U. S. Forest Products Lab. *Ind. Eng. Chem.* 21, 80-4(1929).—Evidence that specific adhesion between wood and glue is necessary for satisfactory gluing was offered by Browne and Truax (*C. A.* 21, 3485). Other workers have maintained that mechanical adhesion alone obtains in wood joints (cf. *C. A.* 21, 3254). It is now shown that the wood joints on which the arguments of the latter rest were probably typical of starved joints (cf. preceding abstr.) and that good joints of the kinds in question satisfy the criteria set forth for specific adhesion.

F. L. BROWNE

The purification of sewage from the city Elmshorn, with special reference to tannery wastes (SNOEK) 14. Studies of adsorption and swelling (KUBELKA, WAGNER) 2. Oil and fat treatment (Can. pat. 285,879) 27. Wetting agents (Brit. pat. 291,070) 18. Turkey red oil substitutes (Fr. pat. 642,392) 27.

Tanning composition. OSKAR SPENGLER AND ALFRED THURM. U. S. 1,698,659, Jan. 8. Salol or 2-naphthol salicylate or other suitable ester of a hydroxyarylecarboxylic acid compd. is subjected to the action of a sulfonating agent such as chlorosulfonic acid which is capable of reacting with H₂O until a sample of the reaction product dissolves in water.

Synthetic tanning compositions. I. G. FARBENIND. A.-G. Brit. 291,245, June 18, 1927. S is condensed under alk. conditions with the water-sol. condensation products obtained by reaction between CH₂O and phenol, or its homologs or halogen derivs., and sulfites. For use in tanning a soln. formed by the reaction products is acidified and boiled to remove SO₂. The products obtained may be used with various other tanning compns. Examples are given.

Spray desiccation of chrome tanning liquors. CLYDE D. MARLATT AND WALTER H. DICKERSON (to Marlatt Industrial Waste Products Corp.). U. S. 1,698,505, Jan. 8. In order to convert chrome tanning liquor into dry powdered form it is sprayed into a hot gaseous drying medium after preliminary heating of the liquor to a temp. of about 115°. An app. is described.

Leather-coating composition. SOC. ANON. FRERICUIR. Swiss 127,041, Sept. 20, 1926. The compn. comprises a cellulosic varnish contg. at least one aliphatic acid. A suitable compn. comprises acetylcellulose (6 parts), acetone (70 parts), AcOH (6 parts), amyl acetate (12 parts), ethyl glycollate (5 parts), and amyl ricinoleate (3 parts).

Waterproofing leather. HENRY V. DUNHAM. Can. 285,960, Dec. 25, 1928. Leather is waterproofed by impregnating with a hot molten mixt. contg. about 78 to 85% of paraffin wax, and at least about 10% of rubber dissolved therein, such mixt. having been heated to about 150°, to impart the desired readily penetrating property thereto. Cf. *C. A.* 22, 3316.

Imitation leather. C. E. SIMPSON. Brit. 291,890, March 12, 1927. Woven fabric with a raised or pile surface is printed or grained on one face to resemble leather or in a desired design and then treated with a compn. contg. cellulose acetate or other suitable coating material and may be embossed. Various other details and modifications of the treatment are also described.

Leather-like substance. ALFRED EHRENREICH. Fr. 641,513, Sept. 27, 1927. A substance which can be used for clothing, hand bags, or drum skins is made by treating with a tanning agent the large intestine and the stomachic wall of cartilaginous fishes, particularly the plagiostomes.

Gelatin solutions. I. G. FARBERNIND. A.-G. Fr. 642,235, Oct. 13, 1927. See Brit. 279,443 (C. A. 22, 2855).

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

The Research Association of British Rubber Manufacturers. ANON. *Rubber Age* (London) 9, 414-20(1929).—An illustrated description of the new laboratories.

C. C. DAVIS

Dispersoidological investigations on latex. PHILIP SCHIDROWITZ. *India Rubber J.* 76, 875(1928).—A review of a paper by von Weimarn (cf. *Bull. Chem. Soc. Japan* 1928, 157; *Repts. Imp. Ind. Res. Inst.* 9, No. 5(1928)).

C. C. DAVIS

Making rubber goods of latex by electrodeposition. PAUL KLEIN. *India Rubber J.* 76, 879-81(1928).—A description of early expts. and present developments in the Klein process of electrodeposition of rubber (cf. C. A. 19, 3037; K. and Szegvari, C. A. 21, 512, 2576, 2820; K. and Healey, C. A. 22, 4007; Dunlop Rubber Co., K. and Healey, C. A. 22, 4877). Methods involving deposition directly on a metallic surface are preferable to those involving porous diaphragms. Cataphoresis takes place independent of the current strength, whereas electrolytic deposition can take place only above a certain decompn. tension. Therefore, below this tension homogeneous deposits are formed directly on metal with no evolution of gas. This method requires low currents and therefore is slow. Deposition also takes place above the decompn. tension, so that addn. to the latex of certain electrolytes having a lower decompn. tension than water, i. e., OH ions, and which give solid anodic products, can be used. Sulfides and thiosulfates are particularly effective, since S is liberated and forms a homogeneous mixt. with the rubber. The generation of gas at the anode is caused chiefly by OH ions in the serum, and so if these are diminished and an anode which ionizes continuously and combines with the OH ions is used, generation of gas is avoided. The quantity of rubber deposited is a function of the c. d. The following equations (where V is the velocity of migration, H the potential applied, D the dielec. const. of the bath, Σ the absorption potential of the globuloids, μ the internal friction of the liquid, i the current strength and χ the cond. of the liquid): $V = HD\Sigma/(4\pi\mu)$; $H = Ai/\chi$, and $V = (AiD\Sigma)/(4\pi\mu\chi)$ show that the velocity of migration is inversely proportional to the cond. of the bath. These equations were not strictly true in actual expts. but the thickness of the deposit decreased with increase of cond. The concn. of bath is of industrial importance, a change of concn. between 20 and 30% making little difference, whereas with a concn. below 10%, the quantity of rubber deposited varies greatly with slight changes of concn. Deposition must be at a const. rate to avoid continual change of time, c. d. and cond. Methods have been developed for keeping the concn. of the mixt. practically const., a diaphragm between the latex and cathode with the latex compd. inside the diaphragm and contg. the anode causing migration and deposition of rubber on the anode and electroendosmotic flow (the inverse of cataphoresis) through the diaphragm so that the serum passed to the cathode. Since alky., concn. and cond. remain const., the rate of deposition is also const. for a given current. The process has been made very economical, 0.2 kw.-hr. being sufficient for the deposition of 1 lb. of rubber mixt., even with cathode diaphragms. The quality of the vulcanized products is superior to that of the corresponding mixts. made by standard methods of milling. The process offers new uses for rubber, particularly in the coating of metals with soft or hard rubber.

C. C. DAVIS

Stress-strain curves of raw rubber-carbon black mixtures at low temperatures. M. KRÖGER AND WAN-NIEN YAO. Univ. Leipzig. *Gummi-Ztg.* 43, 649(1928).—In expts. on the effect of chilling (-20° to -65°) on the stress-strain curves of raw rubber it was found that the stress-strain curves at low temps. conform closely to the stress-strain curves of the vulcanized rubber at normal temps. Further expts. now show that the incorporation of gas black into raw rubber changes the stress-strain curves at these low temps. in much the same way that it changes the stress-strain curves of the vulcanized rubber at normal temps. With Congo, Para and sheet rubber, 10 parts of gas black per 30 parts of rubber were added, and with crepe, 10 parts per 20 parts

of rubber. The optimum absorption of energy was at -25° , for though at lower temps. higher stresses were obtained, the disproportionately low elongations made the total energy less. The optimum is then, in comparison with that of pure rubber, displaced toward a higher temp., and is also increased in magnitude by the addn. of the gas black. Further details are published elsewhere (cf. *Z. Elektrochem.* 34, 725(1928)). C. C. D.

Blacks for rubber mixtures. WERNER ESCH. *Gummi-Ztg.* 43, 421-2(1928); cf. *C. A.* 23, 306.—A discussion of properties of different types of C black, with particular comments on papers by Kirchhof (cf. *C. A.* 23, 731) and by Johnson (cf. *C. A.* 22, 4273). C. C. DAVIS

Reply to the "corrections" of Dr. W. Esch, Hamburg. F. KIRCHHOF. *Gummi-Ztg.* 43, 422-3(1928).—A further polemical discussion of the properties of blacks. C. C. DAVIS

Determination of sulfur in rubber by the perchloric acid method. EDWARD WOLESENSKY. Bur. Standards, Washington. *Ind. Eng. Chem.* 20, 1234-8(1928).—In a search for a rapid and accurate method for detg. S in rubber, it was found that oxidation by means of Na_2O_2 in a Parr bomb is unsatisfactory when the S content is low, because the samples which can be used are too small for accurate results, and with larger samples oxidation is incomplete. The use of a mixt. of HNO_3 and HClO_4 as described by Kahane (*C. A.* 21, 2817) is also unsatisfactory, but with certain modifications his method may give very good results, and if fusions are unnecessary, it will save time and labor. The chief modifications recommended are the use of more dil. HNO_3 (equal vols. of concd. acid and water), allowing the rubber to dissolve completely on the steam bath before heating more strongly, then heating to gentle boiling until oxidation is complete, and finally destroying the residual HNO_3 by HCl . The use of a larger flask (500-800 cc.) is also recommended, and suggestions are made for the adaptation of this method to the analysis of rubber mixts. which contain Ba, Pb, etc. It is recognized that this method has its limitations and that there are cases where it is inapplicable, but in the majority of cases it should be useful. C. C. DAVIS

Importance of temperature and humidity control in rubber testing. I. Stress-strain and tensile properties. J. E. PARTENHEIMER, et al. *Ind. Eng. Chem.* 20, 1245-73(1928); *Rubber Chemistry and Technology* 1, 515-94(1928); cf. *C. A.* 22, 511.—A report of the Phys. Testing Com. of the Rubber Division of the Am. Chem. Soc. An extensive investigation proves that temp. variations which occur from day to day in an uncontrolled lab. may effect the phys. properties of vulcanized rubber as much as 25-45% in the time of cure, while relative humidity affects the properties relatively little. Furthermore variations in the abs. humidity where the uncured rubber is stored between mixing and curing may affect the tensile strength and modulus as much as does the temp. after curing. Therefore, tests without control of temp. and humidity may be highly erroneous and misleading. The investigation leads to definite recommendations. Uncured rubber mixts. should be conditioned for not less than 24 nor more than 28 hrs. at an abs. humidity of 5.24 grains of water per cu. ft. of dry air (0.012 g. of water per l.), and cured mixts. should before testing be conditioned for not less than 24 hrs. at $80^{\circ} \pm 2^{\circ}$ F. and $45 \pm 3\%$ relative humidity. The testing room should be maintained at $82^{\circ} \pm 2^{\circ}$ F. The time between removing samples from the conditioning cabinets and curing or testing should be not over 2 hrs. If uncured mixts. cannot be conditioned at 82° F., the relative humidity should be that corresponding to the temp. used, which gives an abs. humidity equal to that obtained under the former conditions, viz., 5.24 grains of water per cu. ft. of dry air. It is not necessary to control the humidity of the testing room, a small cabinet humidified with the proper satd. salt soln. or H_2SO_4 soln. being sufficient. A study of the effect of variations of relative humidity before mixing showed negligible differences in stress-strain and tensile properties, so that it is unnecessary to use more than ordinary care in storing rubber and compounding ingredients. The methods used throughout the investigations are described in detail and the results are recorded in tables and graphs. Control of temp. and humidity are not the only variables in testing rubber, and only when all variables are brought under control will the results of various investigators be strictly comparable. C. C. DAVIS

Inaccuracies in determination of acidity of raw rubber by water extraction. A. D. CUMMINGS AND H. E. SIMMONS. Univ. of Akron. *Ind. Eng. Chem.* 20, 1213-4(1928).—Expts. on the detn. of water-sol. acids in raw rubber by direct extn. with hot water showed that high and erratic values are obtained, probably on account of hydrolysis of the esters present. An increase in the acid no. also takes place if the acetone ext. is boiled with water. In the hot water extn. of rubber, the extent of the ester hydrolysis depends upon the time and temp. of extn., extensive hydrolysis occurring only toward

the b. p., which readily accounts for the erratic results of direct extn. where there is uneven heating. To avoid fallacious results in detg. water-sol. acids in rubber ext. first with acetone, and then digest this ext. with water on a boiling-water bath until there is no increase in acidity of the water ext. This is a part of the procedure of van Rossem and Dekker (cf. *C. A.* 21, 195).

Normal aging (of rubber). PHILIP SCHIDROWITZ. *India Rubber J.* 76, 765-6 (1928).—A review and discussion of a paper by McKee and Depew (cf. *C. A.* 22, 2490).

C. C. DAVIS

Reënforcement of rubber by fillers. PHILIP SCHIDROWITZ. *India Rubber J.* 76, 1071(1928).—A crit. review and discussion of a paper by Blake (cf. *C. A.* 22, 4876).

C. C. DAVIS

Rubber thread and tape manufacture. A. E. PENFOLD. *India Rubber J.* 76, 1035-7, 1075-6(1928).—A description of present developments, including the raw materials, methods of compounding, equipment and technic.

C. C. DAVIS

Effect of repeated reclaiming of rubber. GEORGE W. MILLER. Firestone Tire & Rubber Co., Akron. *Ind. Eng. Chem.* 20, 1165-9(1928).—In view of the increasing importance of the problem whether vulcanized rubber can be reclaimed repeatedly without the quality of the successive reclaims becoming poorer and poorer, a representative whole tire reclaim was cured, was then reclaimed by the NaOH process and the cycle repeated 3 times more. The quality of each new reclaim was detd. by tests, before curing, of the plasticity, acetone and CHCl_3 exts., free and combined S and, after curing, of the tensile strength, ultimate elongation, modulus and aging. Repeated reclaiming resulted in a decrease in the CHCl_3 ext., plasticity and ultimate elongation and an increase in the acetone ext., combined S and modulus, while the tensile strength remained practically the same. When incorporated in a tire tread mixt. of relatively poor quality, the modulus increased and the elongation and tensile strength diminished with successive reclamations, while by heating in air at 70° there was little difference in the aging properties of the tread mixts. contg. the successive reclaims. The results show in general that when vulcanized rubber is repeatedly reclaimed and recured, its phys. properties become progressively poorer.

C. C. DAVIS

Some observations with ultra-accelerators. A. D. CUMMINGS AND H. E. SIMMONS. Univ. of Akron. *Ind. Eng. Chem.* 20, 1173-6(1928).—Several thiuramdisulfides, one of them not previously described, were prepd. and their behavior as accelerators was studied with a view to explaining the mechanism of their action and obtaining evidence for or against existing theories of acceleration. The disulfides were prepd. by the method of Braun (cf. *Ber.* 35, 817(1902)). The following data give the thiuramdisulfides prepd. (the 1st one new) the m. p. found and the m. p. recorded in the literature: dimethyldiethyl (I), 72° , -; tetramethyl (II), 146° , 146° ; tetraethyl (III), $69.5-70^\circ$, 70° ; dimethyl (IV), $101.5-102^\circ$, 102° ; dimethyldiphenyl (V), 192° , 198° ; tetramethyl (VI), 105.6° , 106° . IV was almost inactive, whereas II was extremely active (cf. Romani, *C. A.* 16, 854; Twiss, Brazier and Thomas, *C. A.* 16, 2043). On the assumption that inactivity and ease of decompn. may be related, IV was heated alone, with S and ZnO, and with S, ZnO and rubber. In all cases H_2S and MeNCS were evolved. Hence the reaction: $\text{IV} \longrightarrow 2\text{MeNCS} + \text{H}_2\text{S} + \text{S}$ proceeds so rapidly that there is little opportunity for cyclic changes involving the activation of S before IV is irreversibly decompd. (cf. Twiss and Thomas, *C. A.* 18, 1764). IV decompd. slowly at room temp. and more rapidly on the steam bath. Heated in a rubber-S-ZnO mixt., VI first evolves alk. vapors, followed by H_2S at higher temps., the mechanism of which probably depends upon the explanation of Bedford and Sebrell (*C. A.* 16, 855) and of Bedford and Gray (*C. A.* 17, 2797). Addn. of II and the equiv. proportion of VI + S to a rubber-ZnO mixt. gave vulcanizates of the same degree of cure, indicating that the same active substance is found in each case, probably Zn dimethyldithiocarbamate. COS passed into ice-cold NH_4Et , the product dissolved in water, satd. with the I, and evapd. yielded an oil which after purification decompd. slowly on standing at room temp. with evolution of H_2S and sepn. of S, which were increased by the addn. of HCl. Boiling and neutralization of this acid soln. gave NH_4Et . The decompus. probably involved the reactions: $(\text{Et}_2\text{NC}(\text{O})\text{S})_2 \longrightarrow (\text{Et}_2\text{N})_2\text{CO} + \text{COS} + \text{S}$; $\text{COS} + \text{H}_2\text{O} \longrightarrow \text{CO}_2 + \text{H}_2\text{S}$; $(\text{Et}_2\text{N})_2\text{CO} + \text{H}_2\text{O} \longrightarrow 2\text{NH}_4\text{Et} + \text{CO}_2$. An aq. soln. of the oil gave with $\text{Zn}(\text{OAc})_2$ a ppt. (probably Zn diethylmonothiocarbamate), which had some accelerating power. Comparative tests showed that accelerators derived from an ethylamine are more rapid than the corresponding ones from a methylamine. The dithiocarbamates were more active than the corresponding thiuramdisulfides. The data are recorded in detail, including artificial aging tests.

C. C. DAVIS

Accurate method for comparison of scorching qualities of accelerators. H. R.

THIES. Miller Rubber Co., Akron. *Ind. Eng. Chem.* 20, 1223-7(1928).—A discussion of various methods already known for judging the scorching caused by accelerators leads to the conclusion that none is satisfactory and that there is still need for a simple and reliable method. The new method described overcomes to a large extent the shortcomings of previous methods, and is based on the fact that when a rubber-S-accelerator-ZnO mixt. begins to vulcanize its tendency to disperse in gasoline rapidly diminishes. A mixt. is heated for a given time at a definite temp., is then shaken with gasoline under standardized conditions and the obscuring power of the resulting liquid is then measured. An arbitrary point in the degree of obscurity is chosen as the crit. point at which scorching begins. By varying in a systematic way the time, temp. and proportions of S and accelerator and detg. the crit. points at which the soly. of the heated mixts. begin to diminish, it is possible to obtain useful information on the behavior of different accelerators. To obtain an adequate idea of the behavior of an accelerator, crit. point detns. should be made at 2 or 3 temps., one corresponding to the milling temp., another to the warm storing temp. of the mixt. and another at room temp. C. C. DAVIS

Heat transfer in the vulcanization of rubber. T. K. SHERWOOD. Hood Rubber Co., Watertown, Mass. *Ind. Eng. Chem.* 20, 1181-5(1928).—The paper is based upon exptl. data, the results of which are given graphically. The temp. lag which prevails in the heating of rubber articles causes a marked non-uniformity of cure in the product. The theory of an "unsteady state" of heat flow is discussed and a *method of analyzing data on temps. in a rubber article while heated* is described. From data on the temps. at different times during the heating and on the relation between the rate of cure and the temp., the *method for calcg. the resulting vulcanizing effect at different points in a solid rubber object* is shown. A new "water cure" process for tires is described, a process which is very effective in reducing the non-uniformity of cure resulting from temp. lag, and at the same time reduces appreciably the necessary time of vulcanization. C. C. D

Local examination of the tensile strength of textile fabrics, rubber, etc. (SCHUBERT) 13. Decomposition of barium sulfate by solutions of sodium carbonate (WOLESENSKY) 7. Organic solvents and rubber-lined plant (BREXNER) 1. The influence of the reaction of the soil on the development of *Hevea brasiliensis* (KORTLEVE) 15. Carbon black. A study of its volatile constituents (JOHNSON) 18. Impregnating fibrous materials (Ger. pat. 469,602) 4.

Rubber. THE ANODE RUBBER CO., LTD. Swiss 127,539, May 17, 1926. Rubber objects are prepd. from an aq. rubber dispersion by means of a water-permeable mold in which the rubber is deposited, a conglomerating agent being employed.

Forming deposits of latex, etc. COMPAGNIE GÉNÉRALE D'ÉLECTRICITÉ (to Anode Rubber Co. (England), Ltd.). Brit. 201,339, May 27, 1927. Gel-forming substances are added to latex or like suspensions or solns. and the mixt. is subjected to conditions which will form a gel. Gelatin, agar-agar, carrageen moss or albumin and ZnCl₂ are among the substances which may be used. Heating or cooling may also be used for effecting gelling, and the process may be applied to the formation of shaped articles of ceramic material, hard rubber and papier mache. Porous molds may be used and various details and modifications are described.

Treating latex. COMPAGNIE GÉNÉRALE D'ÉLECTRICITÉ (to Anode Rubber Co. (England), Ltd.). Brit. 291,805, June 9, 1927. Aq. rubber dispersions are made viscous (to facilitate dipping, spreading or spraying) by adding polysaccharides, albuminoids or plant exts., such as gum arabic, which form viscous solns. but not jellies, or such as starch, gelatin or agar-agar which normally form jellies but are partially hydrolyzed to destroy this property. NH₃ or amines present in the latex treated may serve as hydrolyzing agents.

Preserving rubber latex. JOHN MCGAVACK and ROY A. SHIVE (to Naugatuck Chemical Co.). U. S. 1,699,368, Jan. 15. A stable uncoagulated rubber latex having a p_H of between 7 and 4.5 contains an org. preservative such as a sulfonic reaction product of cinnamic acid and BuOH capable of exerting its effect on both sides of neutrality. U. S. 1,699,369 specifies treating latex with a sulfonic alkyl aryl reaction product such as a sulfonic reaction product of BuOH and cinnamic acid together with CH₂O to prepare a stable product having a p_H less than 7. Cf. C. A. 23, 731.

Preserving rubber. SILESIA VERREIN CHEMISCHER FABRIKEN. Brit. 291,431, June 2, 1927. Aging is retarded by adding to rubber reaction products formed by reaction between polyhydroxyaldehydes such as aldoses, polysaccharides as milk sugar or hydrolyzed products such as glucose or invert sugar, and amines such as aniline, and β -naphthylamine, *m*-toluylenediamine, urea or *p*-aminophenol.

Treating rubber films. CARL PLAAT. U. S. 1,698,275, Jan. 8. Rubber films are subjected to the frictional action of a narrow rotary surface such as two rolls of different speeds in order to produce ornamental effects.

Forming hollow rubber articles. DUNLOP RUBBER CO., D. F. TWISS AND E. A. MURPHY. Brit. 291,479, Dec. 4, 1926. A fusible or sol. former is dipped in natural or artificial rubber dispersion, drying and vulcanization are effected, and the former (which may be made of fusible metal, wax or mixts. of S and other suitable materials) is removed at any time after drying has been at least partially effected.

Rubber articles. THE ANODE RUBBER CO., LTD. Fr. 642,183, Oct. 11, 1927. The molds for molding latex mixed with fillers, etc., are coated with gelatin, etc., contg. a coagulant such as Na_2SiF_6 , AcOH or a salt of Ca, Mg, Zn or Al. The mold is agitated to make the coating more uniform.

Baseball centers. MILTON B. REACH (to A. J. Reach Co.). U. S. reissue 17,200, Jan. 22. Two hollow hemispheres of rubber compn. are vulcanized, a cork sphere is enclosed between them and the materials are vulcanized together with an interposed layer of quick-curing rubber compn. (The original pat. No. 1,530,410 was issued March 17, 1925.)

Electrodeposition of rubber. S. O. COWPER-COLES. Brit. 291,471, Nov. 20, 1926. Electrophoretic deposition of rubber from aq. dispersions is effected intermittently, to permit of disposal of any gas bubbles which have formed. The anode may be caused to rotate or to vibrate during the deposition. Metal molds may be used such as Cd or Zn or Zn-coated Fe or Al which may be dipped in adhesive such as gum arabic or gum tragacanth or coated with plumbago, French chalk, etc. Coloring, "compounding" or vulcanizing substances may be added, and various details of operation are given.

Coating wires, threads or filaments with rubber, etc. DUNLOP RUBBER CO., LTD., D. F. TWISS AND E. A. MURPHY. Brit. 291,485, Jan. 28, 1927. The material is passed through a bath contg. a concd. and compounded aq. dispersion, in the form of a cream or viscid fluid contg. rubber, gutta percha, balata or the like, and the uniform coating thus applied is dried without allowing it to contact with any foreign body. The coating may be vulcanized. An app. is described and numerous formulas and details for prepn. compns. are given.

Uniting metals in layers with rubberized fabrics. HAROLD GRAY (to B. F. Goodrich Co.). U. S. 1,697,275, Jan. 1. The surface of material such as steel or other metals to be united with rubberized fabric is coated with a film of a reaction product of turpentine with a substance such as trichloroacetic acid, S chloride or SnSO_4 comprising either a strong inorg. non-oxidizing acid or a compd. which by thermal or hydrolytic disson. will give such an acid and the materials are assembled under pressure with the coated surfaces in contact.

Rubber substitute. JEAN BAHR. Fr. 640,967, Sept. 14, 1927. An elastic material resembling rubber is obtained by the action of S or S yielding substances on saturated halogenated hydrocarbons of the group $\text{C}_n\text{H}_{2n+2}$ such as CH_2Cl_2 , CH_2Br_2 , CH_2I_2 , $\text{C}_2\text{H}_4\text{Cl}_2$, $\text{C}_2\text{H}_4\text{Br}_2$, etc., or mixts. thereof in the presence of an aq. alk. or alc. solvent.

Apparatus for vulcanizing tires. DUNLOP RUBBER CO., LTD., H. WILLSHAW, T. NORCROSS AND F. G. BROADBENT. Brit. 291,905, March 19, 1927. Structural feature.

Mold for vulcanizing tires. CLAUDE A. WITTER. U. S. 1,697,703, Jan. 1. Structural features.

Rubber vulcanization. METALLBANK UND METALLURGISCHE GES. A.-G. Brit. 291,438, June 2, 1927. Org. Se compds. (such as those which may be obtained by reaction between H_2Se , NH_3 and benzaldehyde or other suitable aldehyde) are used as accelerators.

Vulcanizing rubber. WILLIAM P. TER HORST (to Rubber Service Laboratories Co.). U. S. 1,698,569, Jan. 8. Phenylpiperidylguanidine is used as an accelerator and other similar compds. also may be used. Cf. C. A. 22, 2685-6.

Vulcanization of rubber. THE NAUGATUCK CHEMICAL COMPANY. Fr. 642,264, Oct. 14, 1927. Vulcanization is accelerated by means of a halogen-contg. or other deriv. of the condensation product of an aliphatic aldehyde having 2-7 C atoms in the mol. with a primary amine. In an example a soln. of the condensation product of heptaldehyde and PhNH_2 in C_6H_6 or CCl_4 is treated with Cl until HCl begins to be evolved; the product contains 26.4% of Cl. Other examples of the prepn. of suitable derivs. of the same condensation product are given.

Rubber vulcanization. SIDNEY M. CADWELL (to Naugatuck Chemical Co.). U. S. 1,698,712, Jan. 15. A rubber compn. is prepd. contg. a metal compd. such as

ZnO together with S and a CS₂-contg. material or deriv. such as hydroxybutyl thiocarbonic acid disulfide and a second compn. is also prepd. contg. rubber, a metal compd. such as ZnO together with S and dibenzylamine or other suitable amine. One of these compns. also contains a material such as phthalic anhydride which will check the vulcanizing action of ingredients associated with the rubber. The compns. are brought together in the form of plies and the amine and CS₂-contg. material are permitted to diffuse throughout the compns. and vulcanization is effected. U. S. 1,698,713, specifies control of vulcanization by prepg. a cement comprising rubber, a Zn compd. such as ZnO, a S-contg. material such as S itself, a CS₂-contg. material or deriv. such as normal butylthiocarbonic acid disulfide, together with phthalic anhydride and C₆H₆. When it is desired to effect vulcanization, aniline is added in excess of that required to counteract the checking effect of the phthalic anhydride. U. S. 1,698,714 specifies controlling vulcanization by treating vulcanized rubber contg. hydroxybutylthiocarbonic acid disulfide or other accelerating ingredient with a material such as NH₃ which will check the functioning of the accelerating ingredient. U. S. 1,698,715 specifies causing a vulcanizing ingredient contained in rubber to react with a substance such as phthalic anhydride for checking the vulcanizing function of the ingredient and then, when desired, adding an agent such as PhNH₂ which will cause vulcanization. Numerous examples and details are given. Cf. C. A. 22, 2856.

CHEMICAL ABSTRACTS

Vol. 23.

MARCH 20, 1929

No. 6

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Developments in temperature indicating, recording and control instruments during 1928. D. I. MATHIAS. *Instruments* 2, 23-5(1929). E. J. C.

Optics of the total-radiation pyrometer. HILDEGARD MIETHING. *Wiss. Veröffentlich. Siemens-Konzern* 6, 135-46(1928).—The reflection and absorption of incident light by the lenses of a total-radiation pyrometer distort the intensity wave-length curve; quartz cuts off wave lengths greater than 5.5μ , while glass cuts off at 4μ . The corrections thus necessitated for measuring the temp. of a black body were calcd., and the results verified by expt. If a gray body is radiating, the observed black-body temp. may be converted to the true temp. by use of a simple factor. But if a selective radiator is measured, the black-body temp. will not be observed, since the pyrometer will be over-corrected (read high) for substances, such as metals, which have a lesser proportion of their radiation in the infra-red, and will be under-corrected for substances, such as oxides, which have a greater proportion of their radiation in the infra-red than a black body. This does not mean that the radiation pyrometer is useless for industrial control, as it can always be calibrated for a particular substance in a particular set of working conditions. BENJAMIN MILLER

Standardization of chemical apparatus construction for the purpose of shortening the time of delivery. ANON. *Chem. App.* 16, 1-2(1929). J. H. MOORE

Remarks on the steps in the technical working of lead for chemical apparatus. KARL KIEFER. *Chem. App.* 16, 2-4(1929).—Notes are given on lining and covering app. with sheet Pb, and on pipes and heating coils. J. H. MOORE

Methods and apparatus of the cryogenic laboratory. XX. A high-vacuum pump of large capacity. W. GAEDE AND W. H. KESOM. *Verslag Akad. Wetenschappen Amsterdam* 37, 819-22(1928).—A diffusion pump of capacity 400 l. per sec. of He at 0.001 mm. pressure is briefly described. The pump is cooled by a water jacket and by an internal cooling coil with a liquid at -10° to -20° . The annular diffusion slot is about 20 mm. wide and has a diam. of 160 mm. The pump contains 7 kg. Hg. It is electrically heated. The capacity for air was found to be 130 l. per sec., const. to the lowest pressures. The initial vacuum used with the pump was 0.15 mm. Hg. B. J. C. VAN DER HOEVEN

A simple apparatus for the determination of carbon dioxide. R. C. WILEY. *J. Am. Chem. Soc.* 51, 222-3(1929).— CO_2 is liberated by a CrO_3 soln. and absorbed in a standard $\text{Ba}(\text{OH})_2$ soln. The app. is very simple and the results are quite accurate. J. H. MOORE

Atomizer for flame coloration. HERMANN EMDE. *Chem.-Ztg.* 52, 1003(1928).—An improved Gouy atomizer is described. J. H. MOORE

A basket centrifugal for fusion work. CARL HÜTTER. *Chem. App.* 16, 5-6(1929).—Cf. C. A. 23, 2, 353. J. H. MOORE

How may we economize in the procuring and use of filter cloths? LEO STEIN. *Chem. App.* 15, 242-3, 280-1(1928).—In most cases cotton is preferable to jute, but one must be guided by experience. Coöperation between manufacturer and user is urged. J. H. MOORE

Measuring temperatures of calender rolls. L. R. KELTNER. *India Rubber World* 79, 60(1929).—A new instrument is described and illustrated. C. C. DAVIS

An improved miscometer. JOHN HOUSTON. *Analyst* 54, 30(1929).—The new measuring device consists of a buret instead of the hollow stopper recommended in a previous paper (cf. C. A. 21, 1). W. T. HALL

A brine circulator for cooling condensers. HAROLD T. GERRY. *Mass. Inst. of Tech. J. Am. Chem. Soc.* 51, 475(1929).—A simple modification of the "air lift" pump as used in some H_2SO_4 plants. E. SCHOTTE

The use of the oscillograph for measuring non-electrical quantities. D. F. MCKER AND W. B. BATTEN. *J. Am. Inst. Elec. Eng.* 48, 126(1929).—The problems of application involve the translation of mechanical phenomena into elec. changes which are proportional. Several typical applications are described showing how motion, time, stress, pressure, etc., are measured. C. G. F.

Recording precision meter for weak currents. C. MÜLLER AND R. FRISCH. *Phys. Tech. Reichsanstalt. Z. tech. Physik* 9, 445-51(1928).—The app. consists principally of a photoelec. cell acting on a string galvanometer with photographic recording device. It is used for the measurement of faint light and other radiations. Several applications are discussed and pictures of the records reproduced. B. J. C. VAN DER HOEVEN

Vacuum tube potentiometer for rapid electromotive force determinations. H. M. PARTRIDGE. *J. Am. Chem. Soc.* 51, 1-7(1929).—An app. is described in which a triode and a tetrode are used in a "simple potentiometer circuit and arranged in such a manner that calibration of the valves and the constancy of their characteristics are unnecessary." J. H. MOORE

A simple reference electrode for potentiometric titrations. H. H. WILLARD AND A. W. BOLDYREFF. Univ. of Michigan. *J. Am. Chem. Soc.* 51, 471-4(1929).—A review is given of the different types of reference electrodes. A simple one is devised, eliminating the use of a standard half-cell and consisting of a Pt wire fused into the tip of a buret. E. SCHOTTE

A convenient form of hydrogen sulfide generator. D. C. BARRUS. *J. Chem. Education* 5, 1428(1928).—An 8- or 10-in. test tube has a hole about $\frac{1}{16}$ in. ground in its bottom, and a stopper and delivery tube fitted to the open end. In it large pieces of FeS are placed, and the tube, supported by a test tube clamp, is then lowered into a cylinder contg. dil. HCl. When the gas is no longer needed the position of the clamp is altered so as to hold the tube out of the acid. The same app. works well for generating H_2 and CO_2 . W. C. EBAUGH

The use of chamotte, stoneware and porcelain as apparatus in the chemical industry. FELIX SINGER. *Chem. Fabrik* 1928, 680 2, 691-2.—A lecture. The 3 products have 3 things in common: (1) formed from Al hydrosilicate, (2) molded from plastic mass and (3) hardens on drying and burning to form sillimanite crystals ($Al_2O_3 \cdot SiO_2$). Chamotte is used extensively in chem. industries wherever the reaction temp. exceeds 200° and where in special cases it reaches 1500° or over. Chamotte high in clay is used for heating basic chemicals while for acid chemicals high SiO_2 ware is required. Where sudden temp. changes occur, the more porous chamotte is desirable, the more compressed product having a higher temp. coeff. Normal chamotte absorbs 10-14% H_2O , but it may be so manufd. as to absorb 0% or 50%. Chamotte is prepd. from fire-resisting kaolin or clay, with from $\frac{1}{2}$ to $\frac{2}{3}$ of the mass made up of previously burnt and nonshrinkable materials. The normal m.-p. limits are cone 26 and 36 ($1580-1790^\circ$). Stoneware is used in acid plants for prepg., storing or shipping these chemicals. It is resistant to acids, mech. wear or temp. changes and is easily obtained in the form of large vessels (6000 l), tubes, flasks, etc. Stoneware is usually colored; it is prepd. from tertiary clays into which is mixed a small quantity of finely powd., previously burnt nonshrinkable materials. It is usually salt glazed. Porcelain is limited in its applicability in chem. industries; it finds most extensive use in labs. It is made from white burning kaolin, quartz and feldspar. Large containers can be made only at great expense; they are rather sensitive to sudden heat changes, fragile, and thus transported with difficulty. S. then discusses the effects of different oxides, carbides, silicates, etc., on chamotte and stoneware, and finally suggests methods of studying porcelains. O. A. NELSON

Wax vessels for experiments using hydrofluoric acid. FRANK C. MATHERS. *Chemist-Analyst* 18, 15(1929).—It is recommended to use old HF bottles, molding the wax around a beaker of the desired size. W. T. H.

Useful intermittent extraction apparatus. C. W. EDDY. *Chemist Analyst* 18, 15-6(1929).—From 2 ring-necked, liter Pyrex flasks, some rubber stoppers, a condenser and a little glass tubing, any one can make an effective extn. app. in about 90 mins. With the app. shown, a limited amt. of solvent is required; the same flask can serve for distn. and for extn., and a large amt. of material can be extd. As set up for use, the lowest member of the app. is a 1. Pyrex flask carrying a 2-holed rubber stopper. One hole serves for the escape of vapors and the other for a siphon tube from the upper flask. Above this is a second flask, like the first, except that an opening has been made at the bottom through which vapors enter from below and liquid is periodically withdrawn by a siphon tube. Around the glass tubing through which vapors enter this second flask, is a cooling coil of glass tubing through which water flows. Above, con-

nection is made with a condenser. When this flask is used for distn. purposes, a solid stopper is inserted at the bottom. W. T. H.

Numbering and lettering of apparatus. GERALD G. GIFFORD. *Chemist-Analyst* 18, 16(1929).—Auto enamel and a toothpick are used. W. T. H.

Marking porcelain and glassware. C. J. SCHOLLENBERGER. *Chemist-Analyst* 18, 17(1929).—Take a piece of discarded alundum ware, wet the surface and rub the glass or porcelain until the surface is ground off a little. Such a surface takes pencil or ink marks better than the sand-blasted spots often provided on beakers. Porcelain and SiO_2 ware can also be marked with concd. H_2PtCl_6 soln. mixed with oil of lavender. On heating, a stain of Pt is obtained. W. T. H.

Waterproof varnish for paper labels on reagent bottles. C. J. SCHOLLENBERGER. *Chemist-Analyst* 18, 17(1929).—Dissolve transparent celluloid in acetone, making a sirupy soln. Old photographic film from which the emulsion has been removed by soaking in warm NaOH is excellent celluloid for this purpose. The varnish can be used for attaching labels and for repairing celluloid articles. W. T. H.

Liquid storage apparatus for supplying solvents. RALPH E. GOODE. *Chemist-Analyst* 18, 18(1929).—The app. consists of a storage tank for holding the desired solvent, with 0.5 in. connection equipped with valves leading from an air storage cylinder. The storage tank for the liquid is also equipped with 2 outlets of pipe fitted with valves. The top of the tank has a 0.25-in. outlet pipe, the tank end being screwed into large cap and this cap in turn being screwed into the storage tank. The large cap is for the admission of liquid in volume. The bottom of the storage tank for the solvent is equipped with a 1-in. outlet pipe with valve for removing sediment. The air cylinder is about one-fourth the size of the liquid storage tank and is filled with air from a tire pump through Schrader valves. W. T. H.

The marking of glass ware by lead etching. JOHN W. ROBBINS. Iowa State Univ. *Chemist Analyst* 18, 18(1929).—Dry some PbO or Pb_3O_4 by heating over a flame. Clean the glass to be etched from finger prints, moisture and grease. Using an ordinary rubber stamp, stamp the glass with ink, shake a little of the PbO over the wording and brush off the excess carefully. Run through a flame until the oxide has a glossy appearance. Do not use too hot a flame. If the deposit becomes black, heat in the outer upper part of the flame. W. T. H.

Protecting combustion tubes. GORDON L. VON PLANCK. *Chemist-Analyst* 18, 19(1929).—A thin clay cover molded in the shape of a split cylinder greatly prolongs the life of tubes used for detg. C in steel. W. T. H.

Prolonging the life of rubber stoppers. C. J. SCHOLLENBERGER. *Chemist-Analyst* 18, 20, 11(1929).—By removing the stoppers while the flask is still hot, there is less danger of shrinkage. When the stopper has shrunk so that it is no longer safe to use, it may be freed by inserting some rubber tubing a little longer than the stopper is deep and then pushing the wet glass connection through the tubing and the stopper. W. T. H.

An electric steam bath. GILES B. COOKE. Univ. of Maryland. *J. Chem. Education* 5, 1447, 1463(1928).—An elec. current is passed through a coil consisting of 4 ft. of No. 24 Chromel "A" resistance wire placed in a 3-neck 3-l. flask and covered with H_2O . Through each small neck of the flask a Cu wire, inside a glass tube, is led to the heating coil, with soldered joints. By using 2-hole stoppers in each small neck, tubes for filling and draining the flask can be provided. A 1-hole stopper passes through the large neck of the flask and carries a tube leading to the steam bath. Safety and convenience are claimed. W. C. EBAUGH

A new carbon resistor. C. A. HARTMANN AND H. DOSSMANN. Siemens-Halske A. G. *Z. techn. Physik* 9, 434-8(1928).—Carbon deposits consisting of cryst. C were produced from hydrocarbons in vacuum furnaces at 600° to 1000° (cf. Hofmann, C. A. 21, 1649) and used for technical resistors. They are 130 to 1300 atom diameters thick (0.02 to 0.2 μ) and therefore cool very efficiently. The sp. gr. is from 2.04 to 2.07; it increases with the temp. of formation. The sp. resistance is 30×10^{-4} ohm cm.; its temp. coeff. is -3×10^{-4} per degree. Its tech. qualities, high overload capacity, etc., are discussed. B. J. C. VAN DER HOEVEN

Natural gas burners as used in the Southwest. HAYLETT O'NEILL. *Power* 69, 268-70(1929).—Various types of burners are described with illustrations. One of the best types of low-pressure combination oil- and gas-burner is set inside the furnace with air openings below the firing floor. Strains in furnace walls due to steep temp. gradients are thus avoided. With the proper air-gas ratio, a highly luminous flame results which, by radiation, results in high heat transfer through boiler tubes. It was found that with this burner 5330 cu. ft. of natural gas was equiv. to 1 barrel of oil. D. B. DILL

Daily, instead of yearly, inventory, as carried out in plants for building apparatus. KARL BEHLERT. *Apparatebau* 41, 1-3(1929).—Sample sheets are shown. J. H. M.

Illumination for Stammers' colorimeter. KARL ZERT. *Listy Cukrovar.* 47, 172-3(1928); cf. *C. A.* 22, 1707.—Z. advocates the use of daylight or artificial light with a compn. of daylight; he eliminates the various color effects of solns. by using color filters.

FRANK MARESH

pH Measurement with the glass electrode and vacuum tube potentiometer (ELDER, WRIGHT) 2. The behavior of the Sb electrode in buffered and unbuffered solutions (LAVA, HEMEDES) 2. Report on the optical axial angle and relation of its plane to the plane of symmetry in mica (ANON.) 2. Electrical methods in hygrometry (BURBIDGE, ALEXANDER) 2. New colorimetric methods (MĚŠT'AN) 2. A precision method for measuring temperatures of *n* liquids on a crystal refractometer and on a microscope slide (ASHTON, TAYLOR) 2.

Educational apparatus for determining the mechanical equivalent of heat. W. D. HILLS. Brit. 292,807, Aug. 30, 1927.

Hydrometer syringe. GEORGE E. ANDERSON. U. S. 1,701,654, Feb. 12. Structural features.

Hydrometer suitable for testing liquids in continuous flow systems. EDWIN L. DENNIS. U. S. 1,701,404, Feb. 5.

Comparison colorimeter or turbidimeter. W. G. EYTON. Brit. 292,337, May 30, 1927.

Electric resistance thermometer suitable for use in cold-storage chambers. SHEMENS BROS. & CO., LTD., and L. G. SALMON. Brit. 292,773, June 27, 1927.

Stirrer construction for mixing slurry or like materials in tanks. R. F. MINOGUE. Brit. 292,714, April 2, 1927.

High-speed mixing or emulsifying apparatus. G. S. P. DE BETHUNE. Brit. 292,592, June 24, 1927.

Filter. SERGE YAKOVENKO and ANDRÉ HÉLÈNE. Fr. 643,172, Oct. 28, 1927. A filter comprises a no. of perforated cylinders inside one another or plates placed together, the perforations of which do not coincide.

Filters. H. CHABAL ET CIE. Fr. 33,291, Mar. 30, 1927. Addn. to 600,282. Porous plates for supporting filter beds for *water*, etc., are described.

Suction filter. MASCHINENFABRIC BUCKAU R. WOLF A.-G. Ger. 470,276, May 28, 1925. The filter has a rotary cell with heated walls. The lead-off tubes for the liquid are only subjected to suction at the periods of their lowest position. At other times they are automatically closed.

Filter with a bed of granular material. JOHN I. GOADE. U. S. 1,700,160, Jan. 29. Structural features.

Air filtering device. AXEL W. KOGSTROM (one half to Allison F. H. Scott). U. S. 1,701,782, Feb. 12.

Filter for air or other gases. ALFRED M. GOODLOE (to American Kreuger & Toll Corp.). U. S. 1,700,126, Jan. 29. Structural features.

Filters for filtering liquids in filter presses. L. A. J. REVEL. Brit. 292,117, June 14, 1927. Structural features.

Rotary vacuum filter. BRINJES & GOODWIN, LTD., L. STEWART (Executive of R. Stewart) and C. F. N. SEAMAN. Brit. 292,644, Feb. 24, 1927.

Filter-cake-discharging apparatus for continuous filters. JASPER A. McCASKELL. U. S. 1,700,772, Feb. 5. Structural features.

Filter-press dialyzers. HEIBIG & CIE. Fr. 642,884, Oct. 22, 1927.

Vertical drying apparatus with rotating plates. BAECHELER KISER ET COMPAGNIE. Fr. 33,264, Dec. 4, 1926. Addn. to 601,168.

Apparatus for drying briquets. FRANCIS M. CROSSMAN. U. S. 1,701,873, Feb. 12.

Apparatus for drying materials of pasty consistency. I. G. FARBENIND. A.-G. Brit. 293,028, June 30, 1927. The material is treated with a current of heated air while carried through the app. as a film on a band of wire netting moving around rollers.

Vacuum drying apparatus for grain or other materials. A. E. JONSSON. Brit. 292,105, June 13, 1927.

Apparatus for drying and recovery of solvents from various materials. I. G. FARBENIND. A.-G. Brit. 292,564, June 22, 1927. The material undergoing drying is passed on a band conveyor through a drying chamber which has inlet and outlet seals to prevent escape of solvent vapor, and either air or an inert gas may be forced into the seals under a pressure greater than that in the drying chamber.

Apparatus for distilling or drying coal or other materials. TROCKNUNGS-, VERSCHWELUNGS-, UND VERGASUNGS-GES. and L. HONIGMANN. Brit. 293,147, April 22, 1927. Heat is transferred from hot gases passing through the upper part of a stationary cylinder, to the material being treated, which is in the lower part of the cylinder, by perforate plates mounted on a rotary or oscillating shaft. Various details and modifications are described.

Evaporation apparatus. EDOUARD C. KREBS. Ger. 470,182, Sept. 26, 1924. The app. has one or more pivoted tubular heating elements which can be swung over near the surface of the liquid.

Evaporator for liquids. G. AND J. WEIR, LTD. and J. SIM. Brit. 292,842, Nov. 22, 1927. An evaporator is specified of the type having superposed chambers with steam pipes arranged in parallel.

Rotating separator for extracting dust, etc., from air or gases. PNEUMATIC CONVEYANCE AND EXTN., LTD. and WM. A. SMITH. Fr. 643,441, Nov. 7, 1927.

Device for gravity separation of oil from water, etc. J. B. MACLEAN. Brit. 293,091, March 26, 1927.

Apparatus (employing a riffled table and air currents) for separating dry solids. MARTIN J. LIDE. U. S. 1,701,621, Feb. 12.

Apparatus for separating hard substances such as pips from fruit pulp. SOCIÉTÉ P. NAVARRE ET FILS. Fr. 643,557, Apr. 11, 1927.

Flotation apparatus for graphite or other material. ANDRÉ LIOTARD. Fr. 643,068, Jan. 15, 1927.

Rotary bed for Röntgen ray apparatus. ERNST POHL. Ger. 470,191 and 470,193, Apr. 22, 1926 and Ger. 470,192, Apr. 11, 1926. Addns. to Ger. 428,476.

Electron tube. EAGLE GES. FÜR RADIOBEDARF A. JACOBI & Z. DEZSÖ. Austrian 111,725, Sept. 15, 1927. One lead to the V-shaped hot wire is attached to the point of the V and the other to a T-shaped holder, the cross piece of which joins the ends of the V.

Electron tubes having several cathode filaments in parallel. LA RADIOTECHNIQUE. Fr. 612,744, Mar. 28, 1927.

Discharge tubes. SIEMENS-SCHUCKERTWERKE A.-G. Fr. 643,300, Nov. 3, 1927. A metal such as Ca or Mg is vaporized, after closing the tube, continuously or repeatedly, whereby any gases liberated during use are permanently removed.

Electric discharge tubes. THE M-O VALVE CO., LTD. Fr. 643,704, Nov. 9, 1927. Cathodes of elec. discharge tubes are made of Fe or Ni. They are covered with a layer of $\text{Ba}(\text{NO}_3)_2$ and heated so that a reaction takes place between the Fe or Ni and the nitrate.

Electric discharge tubes with cathode surface of hafnium. GILLES HOLST and EKKO OOSTERHUIS (to Naamlooze Vennootschap Philips' Gloeilampenfabrieken). U. S. 1,701,849, Feb. 12. Hf is used for the cathode surface of devices such as x-ray tubes, rectifiers, tubes for wireless telegraphy, etc.

Mercury-vapor rectifier. AKT.-GES. BROWN, BOVERI ET CIE. Brit. 292,500, June 20, 1927. The cathode spot is fixed by a member which may be made of W, Mo or Ta or their carbides, and the cathode vessel is formed in one piece with the container or is electrically connected with it. Some structural details are specified.

Thermionic cathode. EARLE E. SCHUMACHER (to Western Electric Co.). U. S. 1,700,454, Jan. 29. Cathodes are formed with a core of metal such as W, Ta or Mo capable of withstanding high temp., a metallic sleeve (which may be formed of Ni, Co or Pt) on the core and a coating of alk. earth oxide on the sleeve. The metal of the sleeve forms an oxide which, when heated in air, reacts with the alk. earth oxide to form compds. which, when heated *in vacuo*, break down to alk. earth oxide.

Coating compositions for electron-emitting elements. LEON McCULLOCH (to Canadian Westinghouse Co., Ltd.). Can. 286,282, Jan. 8, 1929. Dissolve equal parts by wt. of the nitrates of Ba, Sr and Ca in water, add Na_2CO_3 , ppt. the mixed carbonates, and sep., wash and dry them. Add 16 g. of the carbonates to 10 cc. of a 15% AcOH soln. The material produced is a paint-like substance having a consistency of thick cream.

Furnaces. KARL KOLLER. Austrian 111,630, July 15, 1928. The efficiency of furnaces in which gaseous or liquid fuel and air are supplied to a fire space under such pressure that the combustion products have a slight pos. pressure is improved by providing means for maintaining the pos. pressure at a const. value. For instance, the air supply may be made dependent on the pressure of the combustion products.

Furnaces. SOCIÉTÉ D'ÉLECTRICITÉ DE LA RÉGION DE VALENCIENNES-ANZIN. Fr. 642,731, Mar. 26, 1927. In furnaces using powd. coal, a current of air is drawn

across the space below the combustion chamber and is heated by the ashes, which are thereby sufficiently cooled to be immediately removed. The heated air is then mixed with the powd. coal passing to the furnace.

Continuous vertical distillation furnace for coal, etc. JULIEN PIETERS. Fr. 642,769 and 642,770, Mar. 30, 1927.

Coal-dust furnace. FRITZ MARTIN. Ger. 470,179, Sept. 9, 1925. Compressed air enters the combustion chamber through nozzles corresponding in shape with those in the side of the chamber.

Furnace for burning coal dust. RICHARD UHLIG. U. S. 1,701,900, Feb. 12.

Furnaces for utilizing powdered fuels. GEORGE P. JACKSON (to Combustion Engineering Corp. and International Combustion Engineering Corp.). U. S. 1,701,852-3-4-5, Feb. 12. Structural features.

Nozzle furnace. CHARLES W. BURROUGHS. Ger. 470,189, July 8, 1926. The series of nozzles surrounds the flame in order to produce a whirling effect.

Furnace with a combustion chamber formed largely of carborundum or material of like thermal conductivity. HIRAM B. CANNON (to Carborundum Co.). U. S. 1,701,834, Feb. 12. U. S. 1,701,835-6 (Hiram B. Cannon and John W. Cannon) and U. S. 1,701,837-8 (Hiram B. Cannon) also relate to similar and other structural features of furnaces for various purposes.

Brick checker work construction for open-hearth regenerative furnaces or similar apparatus. JULIUS M. BOCEK. U. S. 1,700,398, Jan. 29.

Combustion system for reverberatory and similar furnaces. R. WARSITZ. Brit. 292,146, June 15, 1927.

Apparatus for the automatic regulation of liquid or gaseous fuel and air to burners. PAUL LINKÉ. Fr. 642,726, Mar. 26, 1927.

Burner for coal-dust furnaces. DEUTSCHE BABCOCK & WILCOX DAMPFKESSELWERKE. A.-G. Ger. 469,948, Apr. 2, 1927.

Automatic oil burners for furnaces. CALORIL BURNER CORP. Fr. 643,148, Oct. 25, 1927.

Oil burner. FREDERICK C. FOX. Australia 9390, Sept. 15, 1927. A proportion of the air under pressure is diverted to enter the oil passage in the burner and atomize the entering oil.

Apparatus for washing smoke from boiler furnaces, etc. C. J. SCHOBRONE. Brit. 292,380, Aug. 15, 1927. The app. is provided with spray nozzles and with a rotary shaft carrying staggered baffle plates.

Turbidimeter for vapors, smoke, etc. M. BUCHHOLZ. Brit. 293,034, June 30, 1927.

Apparatus for treating smoke gases with supersaturated steam and water, etc. D. RADULESCU. Brit. 292,118, June 14, 1927. Structural features.

Gas burner. GEORGE BAKER (one-third to Lee McCrory and one-sixth each to A. S. Sands and A. B. Campbell). U. S. 1,700,918, Feb. 5. Structural features.

Gas burner. BERNARD A. GEURINK. U. S. 1,700,886, Feb. 5. Structural features.

Gas-burner construction. CLARENCE H. MORROW (to Hotstream Heater Co.). U. S. 1,702,054, Feb. 12.

Gas-burner construction comprising a plurality of Bunsen tubes. JOHN H. GRAYSON (to J. H. Grayson Mfg. Co.). U. S. 1,700,199, Jan. 29.

Safety device for gas burners of water heaters. ROY W. JOHNSON (to Time-O Stat Co.). U. S. 1,700,316, Jan. 29.

Oil-firing systems for ovens, boilers, etc. FREDERICK C. FOX. Australia 9325, Sept. 12, 1927. Means for establishing the required oil and air pressure are described.

Tunnel kiln. A. HERMANSEN. Brit. 292,781, July 7, 1927.

Annular tunnel kiln. JEAN HEINSTEINSEN. Ger. 470,260, Aug. 17, 1926. The kiln has floats and 3 concentric tunnels of which the outer forms the muffie, the middle the drying tunnel and the inner the pre-drying tunnel.

Retort construction for carbonizing scrap leather, etc. STANLEY B. MATHEWSON and WALTER K. JAMISON (to trustees of Lecar Carbon Co.). U. S. 1,700,684, Jan. 29. Structural features.

Standpipe construction for coke ovens, etc. JOSEPH BECKER (to Koppers Co.). U. S. 1,700,971, Feb. 5.

Jacket-enclosed fire-tube boiler especially for combustible dust. ALLGEMEINE ELEKTRICITÄTS-GES. (Friedrich Reinhardt, inventor). Ger. 470,190, May 10, 1925. Details of arrangement are described.

Device for generating gas for inflating life preservers, etc. STEPHEN O. LANGE. U. S. 1,701,927, Feb. 12.

Device for controlling the pressure of gases supplied to burners. GEORGE KEITH (to Surface Combustion Co.). U. S. 1,701,500, Feb. 12.

Electrically heated outlet device for cylinders containing gases under pressure (to prevent freezing). RHEOSTATIC CO., LTD., and L. SATCHWELL. Brit. 292,395, Sept. 20, 1927.

Bell-alarm device for indicating changes in the specific gravity of a gas. A. H. OLSSON and P. D. PETERSON. Brit. 292,083, June 11, 1927.

Apparatus for effecting continuous feed of solids reacting with gases at high temperatures and pressures. E. HAYWARD. Brit. 292,642, Feb. 22, 1927.

Safety device for preventing back flashing of gas flames. CHRISTEL SCHRAUB. U. S. 1,701,276, Feb. 5.

Gas-analysis apparatus. PLATEN-MUNTERS REFRIGERATING SYSTEM AKTIEBOLAG (to Electrolux, Ltd.). Brit. 292,607, June 23, 1927. Gas is diffused through a porous medium into a measuring chamber and exposed to the action of an absorption medium having a constant absorption capacity such as a liquid of constant compn. passing in continuous flow. Various structural details are described.

Gas-analysis apparatus for determination of the proportion of inflammable gases in a gas mixture. H. T. RINGROSE. Brit. 293,125, April 1, 1927. The gas is ignited in a closed chamber and the degree of vacuum thus produced is measured and may be utilized to light a lamp when the proportion of inflammable material reaches a certain limit. Cf. C. A. 22, 3.

Analysis of gas. LUCIEN PLANTEFOL and GEORGES C. BOULITTE. Fr. 642,930, Oct. 24, 1927. An arrangement of bottles, a buret, and 2-, 3- and 4-way taps is described for the simple, rapid and accurate analysis of gases, particularly respiration gases.

Absorption tower for gases, particularly sulfur dioxide. ALOIS DANNINGER AND A. PORR, BETONBAU-UNTERNEHMUNG, G. M. B. H. Austrian 111,848, Aug. 15, 1928.

Apparatus for irradiating milk and other liquids. FRANZ HOFFMANN. Austrian 111,853, Aug. 15, 1928. The liquid flows downwardly in a thin layer over a cylinder of gauze which encloses the source of radiation.

Apparatus for pasteurizing milk or other liquids in bulk. AAGE JENSEN. U. S. 1,701,777, Feb. 12.

Evaporators for sugar solutions, etc. B. BOULOGNE. Brit. 292,915, June 25, 1927. Devices are provided for cooling the liquid as it passes from one to another of a series of evaporators.

Apparatus for liming sugar juices or mixing other materials. RALPH W. SHAFOR (to Gilchrist & Co.). U. S. 1,701,164, Feb. 5.

Vortex classifier suitable for elutriation of powdered materials. LEONARD ANDREWS. U. S. 1,701,942, Feb. 12.

Device suitable for delivering powdered reagents in measured and regulatable quantities. A. S. LEGG. Brit. 292,713, April 1, 1927.

Device for measuring the flow of fluid currents. PAUL VON VÁGÓ. Ger. 470,238, Oct. 20, 1925. Details of arrangement and formulas are given.

Device (comprising an absorbent pad in a sealed package) for fumigating with hydrocyanic acid, chloropicrin, etc. A. AUTRAN. Brit. 292,547, June 22, 1927.

Identifying crystals. FAYETTE F. READ. Fr. 643,142, Oct. 24, 1927. An app. is described in which crystals, particularly diamonds, are identified by directing a light ray into the crystal and measuring the position of the resulting secondary rays.

Apparatus for clarifying liquid used for drying cleaning, etc. ALAN E. FLOWERS (to De Laval Separator Co.). U. S. 1,701,068, Feb. 5.

Acid-proofing chemical apparatus with synthetic resins. J. K. WIRTH. Brit. 292,334, May 26, 1927. Various compns. and modes of use of phenol-aldehyde resins for making, cementing or coating chem. app. are described. Fibrous material or other inert fillers may be added.

Acidity-testing apparatus. DONALD W. SUTHERLAND, JR. U. S. 1,700,655, Jan. 20. An app. is described which is suitable for titrating milk, cream, etc., to determine their acidity. A float valve in the reagent-supply receptacle serves to operate a pointer which indicates the acidity on a scale.

Liquid air power machine. ALOIS HOHENSINN. Ger. 470,348, Oct. 21, 1927. Construction and operation are described.

Apparatus for the production of foam. NIKOLAUS SANDOR. Fr. 643,276, Nov. 2, 1927.

Use of purified iron for apparatus for use at high temperatures and pressures. I. G. FARBERNIND, A.-G. Brit. 293,077, March 3, 1927. App. suitable for use with

materials comprising H, O or S may be made of iron such as that prepd. from mild steel by treatment with H at 900° or with a weakly oxidizing mixt. of H and water vapor at 550–600° and 150 atm. pressure. The app. may be coated with Cr, W, U, Mn, Al, Ag, Cu or enamel.

Photometric apparatus for inspection and sorting of tin-plated or galvanized sheets, paper, cardboard, fabrics, etc. V. K. ZWORYKIN (to Westinghouse Elec. & Mfg. Co.). Brit. 292,474, June 16, 1927. A series of light sensitive devices serve to "scan" successive portions of the articles as they move past and may serve to control app. for segregating articles of certain characteristics. Numerous structural details are described.

Apparatus for circulating rubber dispersions, etc., to prevent separation of their constituents. DUNLOP RUBBER CO., LTD., R. F. MCKAY, H. WILLSHAW, W. G. GORHAM and R. F. LEE. Brit. 293,072, March 2, 1927.

Apparatus for marking glass articles such as lamp bulbs. DANIEL K. WRIGHT (to General Electric Co.). U. S. 1,701,348, Feb. 5. An app. is described suitable for applying and burning in inks carrying finely powdered enamels of low m. p.

Thermostat for regulating gas burners of water heaters. CLARENCE H. MORROW (to Hotstream Heater Co.). U. S. 1,702,053, Feb. 12.

Thermostat for regulating electric heating devices. JAMES E. SMITH. Australia 9641, Sept. 30, 1927.

Bimetallic thermostat. LAURENCE K. MARSHALL (to Spencer Thermostat Co.) U. S. 1,700,173, Jan. 29. Elements such as those of monel metal and nickel steel are united with an intervening bonding layer of phosphorus bronze or other suitable Cu-contg. alloy.

Thermostatic valve control. CALEB E. SUMMERS and FOREST H. HARTZELL. U. S. 1,700,210, Jan. 29.

Thermostatic valve control device. JAMES L. BREESE, JR. (to Oil Devices Corp.) U. S. 1,700,428, Jan. 29.

Thermostatic control for electric circuits. JOHN M. JOHNSON. U. S. 1,701,680, Feb. 12.

Thermostatic device for controlling electric alarms, etc. FRANK HICKOK. U. S. 1,702,209, Feb. 12.

Thermostatic control for electric heating apparatus. AXEL O. APPELBERG (to Aktiebolaget Birka Regulator). U. S. 1,700,661, Jan. 29.

2—GENERAL AND PHYSICAL CHEMISTRY

FREDERICK L. BROWNE

Recent advances in science: physical chemistry. R. K. SCHOFIELD. *Science Progress* 23, 404–9(1929).—A review of recent work on chem. kinetics in homogeneous systems, and the reactions between ions.

JOSEPH S. HEPBURN

The old and new quantum theory. EUGENE BLOCH. *Rev. gen. sci.* 39, 695–700 (1928).

Funds available in the United States for the support and encouragement of research in science and its technologies. II. CALLIE HULL AND CLARENCE J. WEST. *Bull. Natl. Research Council* No. 66, 5-76(1928); cf. *C. A.* 22, 3558. E. J. C.

Chemistry as a profession. J. W. SHIPLEY. *Can. Chem. Met.* 13, 48-53(1929). E. H.

Acids and bases. NORRIS F. HALL. *The Nucleus* 6, 87-8, 91(1929).—Conflicting definitions of acids and bases are quoted from standard textbooks. When a small amt. of a strong acid is dissolved in H_2O a definite reaction occurs as follows: $HCl + H_2O \rightleftharpoons H_3O^+ + Cl^-$. The condition of any acid in any solvent is the resultant of 2 main factors, (1) the intrinsic strength of the acid as measured by its tendency to liberate a proton according to the reaction $HX \rightleftharpoons H^+ + X^-$, and (2) the tendency of the solvent to pick up protons, as in $H^+ + H_2O \rightleftharpoons H_3O^+$, $H^+ + NH_3 \rightleftharpoons NH_4^+$, and $H^+ + HOAc \rightleftharpoons H^+HOAc$. An acid is a substance that liberates protons, and a base a substance that picks them up, irrespective of the charge of the acid or base. The author's expts. arrange acids in the order of decreasing strength as $HClO_4$, H_2SO_4 , HNO_3 and CCl_3COOH . W. C. EBAUGH

Electrical methods in hygrometry. P. W. BURBIDGE AND N. S. ALEXANDER. *Proc. Phys. Soc. London* 40, 149-55(1928).—The possibility of applying elec. methods to the measurement of humidity is investigated. The 2 methods considered depend on (1) the change in resistance of org. materials when exposed to water vapor and (2) the change in mobility of ions due to water vapor. In neither case is the method suitable for general use, although each could be applied in special cases. B. C. A.

The periodic system. I. **The ionic potential as a periodic function.** G. H. CARLEDGE. *J. Am. Chem. Soc.* 50, 2855-63(1928). If Z and r are, resp., the valence and the radius of an ion, $Z/r = \phi$, the ionic potential. By plotting $\sqrt{\phi}$, against the ionic no., a two-dimensional periodic chart is obtained. The ionic charge may be added to produce a three-dimensional representation which provides for all valence forms of all elements and represents the behavior of H, the eighth group and the rare earths. By introducing the concept of electronic structure an arrangement of families on the basis of the structure of the outer electronic shell is presented which serves to bring out differences among members of a family in the Mendelyev arrangement. II. **The ionic potential and related properties.** *Ibid* 2863-72.—On comparing ϕ with properties of the ions the following regularities are found: Heats of hydration stand in the same order as ϕ . In a series of salts, the heat of soln. (evolution) of the anhyd. salt varies as the ionic potential. Development of acidic properties is closely associated with increase in ionic potential. For exclusively basic ions ϕ is less than 2.2, for amphoteric ions between 2.2 and 3.2 and for acid ions greater than 3.2. Ions forming stable oxy salts occur only in the amphoteric region of potentials. The discharge potentials of cations in fused electrolytes decrease with increasing ϕ . The line of Bltz and Klemm dividing the high-melting, conducting chlorides from the volatile, non conducting chlorides corresponds to an equipotential line at $\sqrt{\phi} = 2.2$. Ionic potentials indicate the order of increasing dissociability of carbonates and nitrates. There is a parallel increase in hardness, as indicated by Goldschmidt's data, and ϕ .

DON BROUSE

The multivalence. A. F. RICHTER. *Z. physik. Chem.* 135, 444-60(1928).—R. considers the influence of stability of the electron configuration striven for in an atom upon the work of detachment. Besides the octet which remains stable to the 6th period, the restricted stability of the shell of 18 (best represented by Pd) and the "coupled" pair shell (as in Hg) are depicted. The influence of the "coupled" pair shell, stabilized in the series of elements, upon the course of the work of loosening or detachment, especially in groups IV and V, is sought and these magnitudes are brought into relation with the chemistry of the elements. The neg. valence function is made known through the positive heat tone. Such deductions of at. models leads to the assertion that multivalent K and N^{---} ions do not exist. G. L. CLARK

A determination of the atomic weight of nitrogen occluded in fergusonite. H. P. CADY AND HARRY UNANGST BRECHER. Univ. of Kansas. *Science* 48, 594-6(1928).—1800 cc. of gas was obtained from Norwegian fergusonite. The N_2 was absorbed from the gas by hot metallic Ca, and was converted into NH_3 by hydrolysis, and then into NH_4Cl . The Cl in a weighed sample of the salt was detd. gravimetrically, and the at. wt. of the N_2 was calcd. The "Norwegian" NH_4Cl gave an at. wt. of N_2 only 0.02% greater than that of a control sample of N_2 from liquid NH_3 . The possibility of an isotope of N_2 of at. wt. 15 (a possible decompn. product of K) is therefore disposed of.

R. L. DODGE

Atomic (magnetic) moments. PIERRE WEISS AND G. FOËX. *Compt. rend.* 187, 744-6(1928).—To test the various theories of at. magnetism, W. and F. present a table of those at. magnetic moments which, in their judgment, are most accurately known. At zero abs. the moments of Fe and Ni are given as 11.00 and 3.000 magnetons, resp. In the entire table, only 2, viz., Fe^{++} in ammoniacal sulfate soln. and Co^{++} in the hexagonal sulfate, differ from integral nos. by more than the exptl. error.

W. W. STIFLER

The Debye-Hückel theory and stellar atmospheres. J. A. GAUNT. *Month. Not. Roy. Astron. Soc.* 88, 369-77(1928).—Mathematical. While showing some indications in favor of the Debye-Hückel theory, the reasoning developed is claimed to indicate that statistical mechanics provides no firm basis for the use of Boltzmann's theorem on an atomic scale. A summary is also given of an unsuccessful attempt to distinguish between bound and free electrons in the manner suggested by Eddington.

B. C. A

Rare earths in the stellar atmospheres. LUIGI ROLLA AND GIORGIO PICCARDI. Reale Univ. Firenze. *Gazz. chim. ital.* 58, 521-32(1928).—A review of present knowledge concerning the presence and distribution of rare earths in the fixed stars.

C. C. DAVIS

The fusibility of the elements and the electronic numbers. P. VINASSA. *Atti accad. Lincei* 8, 121-5(1928).—At. wt. is a static conception of an element; the electronic no., on the other hand, is dynamic and should be more significant of phys. changes. Fusibility must be a function of the no. of electrons, as well as of the nucleus, so that if there is a relation between the electronic no., N_e , and the abs. temp. of fusion, T_f , it should be a simple no., $\epsilon = T_f/N_e =$ coeff. of fusion. For He, $N_e = 2, T_f = 1^\circ$, and thus $\epsilon = 0.5$, so that all elements must have a coeff. $= \epsilon$ which is a multiple of 0.5. The temp. of fusion so calcd. agrees with the values found by expt. except for Sb, which is polymorphic. A graph is also shown in which the value ϵ (ordinates) is plotted against N_e (abscissas). As a corollary of the above relation, one may consider the body solidifying at 0° , abs. that is $\epsilon = 0 = 0^\circ/N_e$. This is possible when $N_e = 0$, but $N_e = 0$ is the proton alone, which should, therefore, solidify at zero absolute

A. W. CONTIERI

The allotropic modifications of phosphorus. A. SMITS. *Compt. rend.* 187, 980-2(1928).—P has 3 allotropic forms: α_1 , and α_2 stable at room temp. and β stable at higher temps. They can be studied by fractional distn. at a low temp. or by heating white P at varying temps. and pressures and for varying times, then lowering the temp. until changes cease to take place. Nicolaieff (*C. A.* 22, 3324) measured the changes of vapor pressure of such mixed crystals as a function of the density. The results indicate 3 allotropic forms instead of the 4 suggested by Nicolaieff.

AMY LEVESCONTE

Electrical resistance of titanium and zirconium at low temperatures. P. CLAUSING AND G. MOUBIS. *Physica* 7, 245-50(1927).—With Ti and Zr at $70-273^\circ$ abs., the dependence of elec. resistance on temp. is normal (cf. Koenigsberger and Schilling, *C. A.* 4, 3160). The sp. resistance at 273° is 0.80×10^{-4} and 0.41×10^{-4} , resp., and the temp. coeff. 0.00469 and 0.00438.

B. C. A.

The fluorine tension of metal fluorides and the chemical constants for fluorine and hydrogen fluoride. KARL JELLINEK AND A. RUDAT. Techn. Hochschule, Danzig. *Z. anorg. allgem. Chem.* 175, 281-320(1928).—Reduction equil. at temps. from 100 to 800° were measured for AgF , CuF_2 , PbF_2 , NiF_2 , CoF_2 , FeF_2 , FeF_3 , FeF_4 , CdF_2 , ZnF_2 , CrF , to CrF_3 , CrF_2 and MnF_2 . For FeF_2 , the equil. was approached from both sides, viz., $FeF_2 + H_2 \rightleftharpoons Fe + 2HF$. The following formula expresses the dissoen. of HF into the elements: $\log p_{H_2}^2/p_{HF} = (128000/4.57T) + (4.82/4.57) - (28000/T) + 1.05$. The F tension curves of the fluorides enable calcn. of the heats of formation as follows: PbF_2 , 155,600, NiF_2 , 157,500, CoF_2 , 160,700, $2FeF_2 + F_2 = 2FeF_3$, 158,100, FeF_2 , 154,200, FeF_2 , 233,250, CdF_2 , 162,200, ZnF_2 , 172,700, $2CrF + F_2 = 2CrF_2$, 157,900, CrF_2 , 152,000, CrF , 230,950 cal. per mol. These compare well with calorimetric

values. The chem. const. of F and HF are calcd. to be, resp., $+0.7 \pm 0.3$ and -1.0 ± 0.3 .

G. L. CLARK

Thermal expansion of magnesium and some of its alloys. PETER HIDNERT AND W. T. SWEENEY. *Bur. Standards J. Research* 1, 771-92(1928).—Three types of equipment were used (a) precision comparator (cf. Souder and Hidnert, *C. A.* 20, 2568); (b) interferometer (*Bur. Standards Sci. Paper* No. 393); (c) vitreous silica tube. Method (c) is described. The Mg used contained less than 0.03% impurities. The linear thermal expansions of 6 samples were measured over various temp. ranges between -183° and $+500^\circ$. The expansion of magnesium between 20° and 500° is represented by the following av. equation: $L_t = L_0[1 + (24.80t + 0.00961t^2) 10^{-6}]$. The Al content of the Mg-Al alloys varied from 4.36 to 10.35%. The expansions were measured between 20° and 300° . In nearly every case the coeffs. of expansion of extruded alloys are slightly less than those of cast alloys. For the range 20° and 300° the coeffs. of these Mg-Al alloys are practically the same as the coeffs. for Al-Cu alloys containing from 4 to 12% Cu. The addn. of 0 to 10% Al to Mg causes almost no change in the coeffs. of expansion. The expansion curves of the Mg-Al alloy (10% Al) which was extruded and heat treated show crit. regions above 200° . The Mg-Al-Mn alloys had an Al content ranging from 0.01 to 4.14%, while the Mn varied from 0.27 to 0.91%. The addns. of Mn caused slight changes in the coeffs. of expansion. The av. coeffs. detd. are: Mg $20-100^\circ$, 26×10^{-6} ; $20-200^\circ$, 26.9×10^{-6} ; $20-300^\circ$, 27.9×10^{-6} ; $20-400^\circ$, 28.8×10^{-6} ; $20-500^\circ$, 29.8×10^{-6} ; Mg-Al alloys $20-100^\circ$, 25.4 to 26.4×10^{-6} ; $20-200^\circ$, 26.1 to 27.8×10^{-6} ; $20-300^\circ$, 27.7 to 28.1×10^{-6} ; Mg-Al-Mn alloys $20-100^\circ$, 25.6 to 26.6×10^{-6} ; $20-200^\circ$, 26.4 to 27.3×10^{-6} ; $20-300^\circ$, 27.2 to 28.1×10^{-6} .

A. J. MONACK

The electrolytic preparation of magnesium amalgam and its decomposition in air. N. V. KONDIRYEV. *J. Russ. Phys. Chem. Soc.* 60, 545-51(1928).—A current of 0.05-0.06 amp. (at 12-15 v.) was passed through an Et_2O soln. of EtMgBr , the negative electrode being Hg and the positive Mg. The Mg content of the resulting mixt. of amalgam and excess Hg was less than 1% but was increased to about 2% by heating and squeezing out the liquid Hg. Both the electrolytic preps. and solns. of Mg in boiling Hg decomp. in air, the reaction being $\text{Mg} + 2\text{H}_2\text{O} \rightarrow \text{Mg}(\text{OH})_2 + \text{H}_2$. Thus, the max. gain in wt. corresponds to $\text{Mg} \rightarrow \text{Mg}(\text{OH})_2$, and an equiv. amt. of H_2 is given off. The decompn. velocity decreases with rising temp. This is not due to the formation of inert Mg-Hg compds., since the temp.-cond. and cooling curves of the amalgams were found to be continuous. Furthermore, the Mg amalgam is acted on at all temps. by air satd. with H_2O . K. concludes that the temp. effect is due to the decrease in relative humidity of air.

B. SOYENKOFF

Behavior of bismuth films in the magnetic field. FRIEDRICH GROSS. *Z. Physik* 50, 100(1928).—Bi films (0.3 to 3μ in thickness) change in resistance in a magnetic field similarly to a Bi spiral. The change is greater the thicker the film, but the effect is only about half that for a Bi spiral under similar conditions. The method of prepn. affects both the sp. resistance and the change in resistance. For very thin films the change in resistance depends upon the angle between the plane of the film and the lines of magnetic force, but for thicker films the inclination has no effect. W. W. S.

Volta effect. E. DUBOIS. *Compt. rend* 186, 1832-3(1928).—The Volta effect, measured in water vapor, between a fixed, electrically heated, cylindrical spiral electrode of the metal studied, and a cool mobile cylindrical electrode, shows differences of about 0.1 v. for Fe, Ni, Mo, Al, or Cu, but none for Au, Ag or Pt (*C. A.* 21, 3536). The metal becomes more electropos. and the change is a qual. indication of the action of water vapor on the metal.

B. C. A.

Conductivity and Hall effect in sputtered platinum films. A. RIEDE. *Z. Physik* 48, 302-9(1928).—The cond. of Pt films sputtered on glass in the presence of H is proportional to the thickness of the film in the range 4.7-136 $m\mu$. The Hall effect in such films is const. until the thickness is reduced below 30 $m\mu$, when the magnitude of the effect diminishes rapidly.

B. C. A.

Disturbance of the superconductivity of mercury by a magnetic field. W. J. DE HAAS, G. J. SIZOO AND H. K. ONNES. *Arch. néerland. sci.*, III A, 11, 1-47(1928).—The hysteresis effect in the disturbance of supercond. which has already been found in the case of Sn (cf. *C. A.* 21, 690, 3305) was also found for Hg. The effect was observed in all cases examd. While the increase of resistance as the field was increased was regular in the majority of instances, the return to a state of supercond. as the field was diminished occurred in a series of jumps, the no. and extent of which varied for the different resistances used. It is supposed that the difference in the intensities of field when these discontinuities occur is due to the different orientation of crystals

in relation to the field. The hysteresis effect, and also the discontinuities in the curve, were obtained both in transverse and in longitudinal fields, although the position of the discontinuities was different in the 2 cases. The area of the hysteresis diagram varies with temp. The relationship between the temp. and the strength of the field when the resistance has been half restored can be expressed by a straight-line graph. It is also shown that when a superconductor is placed in a magnetic field of sufficiently great intensity the resistance curve shows no anomalies.

B. C. A.

Superconductivity of gallium. W. J. DE HAAS AND J. VOOGD. Univ. Leiden. *Verslag Akad. Wetenschappen Amsterdam* 37, 702-5(1928).—In accordance with former results, Ga does not show supercond. even at 1.1°K. It is believed that supercond may appear at a lower temp. The presence of In decreases the resistivity at low temp. At about 1.1°K., the resistivity of Ga is very sensitive to the current intensity used for the measurements.

ALBERT L. HENNE

Electrical conductivity. W. J. DE HAAS. Univ. Leiden. *J. phys. radium* 9, [6], 265-77(1928); cf. *C. A.* 20, 2779; 21, 1747, 3305; 22, 4287.—Many expts. on supercond. in the work of H., Onnes, Sizoo, *et al.*, are not in agreement with the free-electron theories of cond. Sn becomes superconducting at 3.7°K. When in thin films over Cu, it behaves like Sn below this temp., but above, it has the resistance of Cu. If the electrons are free to move as gas mols. between the metal atoms, there should be some diffusion of electrons from metal to metal and not the sharp break in resistance at 3.7°K. By studying the cond. of single crystals in a magnetic field, there is found a difference when the axis of the crystal is parallel and when it is perpendicular to the field; yet no change is observed when the axis is maintained perpendicular to the field whether the current is in the same or opposite direction. There is no elec or magnetic influence on the resistance in this case and it can be explained by direct movement of electrons from atom to atom, rather than by free electrons. The discontinuities and hysteresis of superconducting metals below their leap point (*C. A.* 20, 1170) calls for an explanation other than that of free electrons.

A.S. CARTER

Relation between polarization and association. JOHN W. WILLIAMS. Univ. of Wis. *Proc. Natl. Acad. Sci.* 14, 932-6(1928).—Data published by W. (*C. A.* 21, 3151, 3783) can be used to test Rolinski's treatment of the Debye modification of the Clausius-Mosotti law for calcg. degree of assocn. of a liquid. R assumes that the resultant dipole moment of 2 associating mols is zero (cf. *C. A.* 23, 29) and concludes that the degree of assocn. is the larger the greater the dipole moment. W's studies of acetone, ethyl acetate, methyl acetate, ethyl ether and CHCl_3 in CCl_4 show R's sweeping conclusions to be unjustified. $\text{C}_6\text{H}_5\text{OH}$ and $\text{C}_6\text{H}_5\text{CO}_2\text{H}$, which are admittedly assocd. by ordinary criteria, show no change in molar polarization from extremely dil. to satd. solns in C_6H_6 and are by R's criterion zero associated.

A. P. SACHS

The electrical moment of molecules. A. KIRRMANN. *Rev. gen. sci.* 39, 598-603 (1928).—K. compares values of the mol moments for HCl , SO_2 , H_2O , CHCl_3 , EtOH , AmOH , Et_2O and $\text{C}_6\text{H}_5\text{NO}_2$ obtained by several workers and by different methods, and shows that all are of the order of 1 or 2×10^{-18} , so that there is little question about the existence of the mol. moment. As regards the worth of individual detns., exptl. methods and calcns. there is much uncertainty. A bibliography is appended.

L. A. SARVER

A determination of the Stefan-Boltzmann radiation constant using a Callendar radio balance. F. E. HOARE. *Phil. Mag.* [7], 6, 828-39(1928).—The concordance of the results obtained with the radio balance under widely differing conditions shows that the method used for evaluating the abs. measure of radiation is extremely satisfactory, and that the instrument is well suited for this purpose. The instrument has the further advantages of being easy to manipulate, quick in working and accurate. The value $\sigma = 5.725 \times 10^{-8}$ is obtained.

GEO. GLOCKLER

New colorimetric methods. F. MEŠT'AN. *Chem. Obzor.* 3, 367-72(1928). After discussing the defects of present color detns. the photometric methods based on Ostwald's color theories are sketched. A new colorimeter "Stupo" was constructed which proved to be 10 times more sensitive than the photometers used in the brewing industry, permitting detns. of slightly turbid and colloid solns.

JAROSLAV KUČERA

The crystallographic foundations of crystal-structure analysis. H. MARK. *Z. Metallkunde* 20, 342-6(1928).—The development of crystallographic theories, *e. g.*, of the axial systems, the point groups, and space groups, is traced historically and the significance of the theories and their practical results for modern x-ray work are outlined.

R. L. HERSHEY

Spontaneous and linear crystallization velocity in binary mixtures. W. RAWITZER. Kaiser-Wilhelm-Inst. für Silicatiforschung, Berlin-Dahlem. *Z. anorg. allgem. Chem.*

175, 321-34(1928).—With the aid of Volmer's theory of crystal growth and consideration of reaction kinetics, relations are derived between the velocity of linear crystn. and the ability to crystallize spontaneously in supercooled melts, and between the velocity of crystn. and concn. These relations have certain analogies in spite of the great difference in the influence of temp. upon them. The relation for the linear crystn. velocity in simple binary mixts. is in agreement with the expts. of Tammann and Bot-schwar. An exptl. trial for the spontaneous crystn. velocity with the simple binary system palmitic-stearic acids shows satisfactory agreements in the limit although complicated in alloys.

G. L. CLARK

The constitution of hydrated crystals. M. A. RAKUZIN. *Bull. soc. chim.* **43**, 984-8(1928).—After having studied the various hydrates and their stability R. believes that we must settle the question as to the nature of the linkage of H_2O of crystn. He believes that the theory of Wurtz should be developed further. The formulas of W. for $CuSO_4 \cdot 5H_2O$ and $CuSO_4 \cdot NH_3 \cdot 4H_2O$ may be written

R. believes with W. that it is the metal and not the acid radical of a salt which attracts the H_2O

E. G. VAN DEN BOSCHE

Structure of topaz. $[Al(F,OH)_2]_2SiO_4$. N. A. ALSTON AND J. WEST. *Proc. Roy. Soc. (London)* **A121**, 358-67(1928). Topaz is holohedral. The O and F atoms (regarded as of equal size) together form a close-packed assemblage which belongs strictly to neither the cubic nor the hexagonal types of close-packing, but which may be regarded as a combination of these two types. Some of the more complex structures not yet analyzed, exhibiting certain features of close packing but not belonging to the hexagonal or cubic type, may be based on some such arrangement as in topaz, the essential feature of all the types being that they represent ways in which identical planes consisting of similar atoms in contact may be closely stacked together, one on top of the other, so as to form a series of layers in periodic succession. In topaz, the results appear to indicate the 4 atoms about each Si atom are O, while of the 6 about each Al atom, 4 are O and 2 F.

W. WEST

Tetrahedral carbon atom and the crystal structure of pentaerythritol. A. HET-TICH, A. SCHLEERDE AND E. SCHNEIDER. *Naturwissenschaften* **16**, 547(1928); cf. *C. A.* **22**, 895. The authors' exptl. results can be interpreted only in terms of a tetrahedral mol. structure, as against the pyramidal structure (cf. Weissenberg, *C. A.* **21**, 3776).

B. C. A.

Dispersion of magnesium sulfide. M. HAASE. *Z. Krist.* **66**, 236-8(1927).— MgS has $n_{D589} 2.284 \pm 0.002$, $n_{D570} 2.277 \pm 0.002$, $n_{D515} 2.265 \pm 0.001$, $n_{D410} 2.259 \pm 0.001$, $[F] 1 \pm 3$.

B. C. A.

The crystal structure of Cu_3Al_4 . (Copper-aluminum.) A. J. BRADLEY. *Phil. Mag.* [7], **6**, 878-88(1928). Powder photographs of δ Cu_3Al contg. 16-19% Al show a cubic structure with 52 atoms per unit cell. The space-group is T_d^d , and there are eight sets of structurally equiv. atoms. There are 36 Cu atoms and 16 Al atoms in each unit cube, corresponding to the formula Cu_3Al_4 . The structure is essentially of the $CaCl_2$ type, each lattice point being replaced by a cluster of 26 atoms, with tetrahedral symmetry. The cluster around the center of the unit cell contains a different number of Al atoms than that around the corners of the unit cell. The coordinates of the atoms are not appreciably different from those in the alloy Cu_3Zn_4 .

GEO. GLOCKLER

Report on the optical axial angle and relation of its plane to the plane of symmetry in mica. ANON. *J. Sci. Instruments* **5**, 577-80(1928).—The angle (in air) between the optical axes is measured with the aid of a simple app. consisting of 2 Nicol prisms set at 45° to the vertical plane, with the crystal under investigation mounted between them. The crystal is rotated until one of the hyperbolic "brushes" cutting the interference pattern crosses the center of the field vertically, then further rotated until the other brush is in the center of the field. The angular difference is the angle between the axes, which varies between 55° and 75° for muscovite micas, 5-25° for phlogopite micas, and 0-5° for biotite micas.

R. J. HAVIGHURST

The discordance between the thermodynamics of gases and the kinetic theory.

KAMEKICHI SHIBA. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 357-62, Abstracts 1, 33(1928).—Under the ordinary assumption that the mols. of a gas are all similar, perfectly elastic spheres with a force of mutual attraction varying as x/r^n , the kinetic theory shows that the equation of state of the gas is $pV + (a/V) = RT \dots$ (A), provided that for simplicity the mol. diameter is taken as negligibly small. It is proved, by calcg. the virial, that the total potential energy of the gas in vol. V , is $E_p = -3a/(n-1)V \dots$ (B). Therefore, the total energy of the gas is $U = -(3a/(n-1)V) + CT \dots$ (C). On the other hand, as a direct consequence of the second law of thermodynamics: $(\partial U/\partial V)_T = T(\partial p/\partial T)_V - p \dots$ (D). The relation D is not satisfied by A and C, unless $n = 4$, which is not plausible. G. L. HENNE

Critical isotherms and the equation of state of A. Wohl. RUDOLF WEGSCHEIDER. *Univ. Wien. Z. physik. Chem.* 135, 362-7(1928).—Polemic with K. Wohl and A. Wohl (*C. A.* 8, 1895; 16, 868, 869; 22, 3074). Remarks on the preceding paper of R. Wegscheider. KURT WOHL. *Ibid* 368. G. L. CLARK

The equation of state of a substance at the absolute zero of temperature, and properties connected with it. R. D. KLEEMAN. *J. Franklin Inst.* 206, 631-46(1928); cf. *C. A.* 23, 319.—The equation of state is mathematically derived from thermodynamic considerations. Max. work, characteristic const. for a substance, additive nature of the at. vols. of a mixt., pressure at any given state, coeffs. of compression and mass addn., work of compression and internal energy, heat and work of evapn., zero of the internal energy of a substance or mixt. under constraint, magnetic properties of inductivity, mixing substances under a pressure, and the radiation properties of a substance are discussed and an equation is derived for each. In the equation $k = M_a A_0 / V_{a0}$, k is an abs. const. for the pure substance a and one of the important consts. of nature. In this equation M_a is the no. of mols. of the substance a ; A_0 is a characteristic const. of the substance at zero abs. and V_{a0} is the vol. occupied by the substance under its own vapor pressure at zero abs. F. E. BROWN

An equation of state for gaseous mixtures. I. Application to mixtures of methane and nitrogen. JAMES A. BEATTIE. *Mass. Inst. Tech. J. Am. Chem. Soc.* 51, 19-30(1929).—The equation of state proposed by B. and Bridgeman (*C. A.* 21, 3146), $p = (RT(1 - \epsilon)/V^2)(V + B) - A/V^2$ was applied to mixts. of CH_4 and N_2 by using the following method of calcg. the consts. of the mixt. from those of the pure constituents. The consts. R , a , B_0 , b and c , which contain the dimension of d to the first power are combined linearly; e. g., $B_{0x} = B_{01}(1 - x) + B_{02}x$; and for A_0 by $A_{0x} = (A_{01}(1 - x) + A_{02}(x))$. It is then possible to write a single equation by means of which pressures for all compns. of CH_4 and N_2 mixts. can be calcd. from temp. d . and the compn. Very satisfactory agreement between observed and calcd. pressures was obtained. J. H. PERRY

Vapor pressures of related compounds. The application of Duhring's rule. A. R. CARR AND D. W. MURPHY. *College City of Detroit. J. Am. Chem. Soc.* 51, 116-21(1929).—The Duhring lines representing the vapor pressure data for each one of a family of substances intersect in a common point. The requirements for the construction of a Duhring chart for a family of substances are: (1) the vapor pressure of some reference substance must be accurately known, and (2) at least two b. ps. at different pressures of two substances in the family should be detd. in order to establish the common point of intersection. J. H. PERRY

Determination of vapor tension of chloropicrin at temperatures around 100° . H. BLASZKOWSKA-ZAKRZEWSKA. *Roczniki Chem.* 8, 210-8(1928).—The vapor tension of chloropicrin was detd. at 98 – 105° in Swientoslawski's ebullioscopic thermostat by the air-current method, which consists in detg. from the loss of wt. the quantity of substance carried away at the given temp. by a definite amt. of air. The app. consists of a 500-600-cc. flask A connected by a narrow 28-cm. tube with the thermostat proper, C a cylinder of 55 mm. diam. which carries a thermometer, a syphon fused into the bulb of A and a reflux condenser. The latter is connected with the pressure-regulating system. The app. in which the air current is satd. with the vapors was constructed by Wojnicz-Sianozecki and resembles Gahl's wash bottle (*Z. phys. Chem.* 31, 178(1900)). The velocity of the air current was 300 cc./min. The mean error was 0.6 – 0.8° . A control expt. with *toluene* gave for 100.2° and 100.4° 559 and 562.6, resp., while an extrapolation of Kahlbaum's values (Landolt-Börnstein Tabellen) gives 562.8 and 566.8. The values obtained were: 98° , 502.1; 100.0° , 532.0; 102.0° , 564.4; 103.0° , 567.6; 104.0° , 583.0; 105.0° , 597.0. The curve $\ln p - 1/T$ is almost a straight line. In view of the possible errors, too high velocity of the air current and carrying over of liquid drops, the detns. will be repeated by another method. MARY JACOBSEN

Method for the determination of vapor tension of very small quantities of substance. Vapor tension of chloropicrin. H. BLASZKOWSKA-ZAKRZEWSKA. *Roczniki Chem.* 8, 219-28(1928); cf. Smith and Menzies, *C. A.* 4, 2595.—The immersed-bulb method permits detns. of vapor tension with 0.03-0.5 g. The bulb was placed in the ebullioscopic thermostat for the detn. of the vapor pressure of CCl_3NO_2 at 97-105°. Water and 25-30% CaCl_2 were used as boiling liquids. A CaCl_2 soln. (d. 1.44, b. 120°) served as immersion liquid. For detns. at 78-96° a paraffin bath served as a thermostat. The error was 0.3% in the ebullioscope, and 0.8-1% in the ordinary thermostat. For toluene 563.4 at 100.2° instead of 562.8 (Landolt-Börnstein). For water the values at 65-88° were 0.6-0.5% lower than those in L.-B. The following values were obtained for CCl_3NO_2 : 98.0°, 491.4; 100.0°, 524.3; 102.0°, 558.2; 103.0°, 577.9; 104.0°, 595.2; 105.0°, 612.8. The results differ considerably from those obtained by the air-current method and may be considered more trustworthy, because of the exptl. errors inherent in the latter and because Avogadro's law, which underlies the calcs. of vapor tension by the dynamic method, probably does not obtain for satd. vapors. The curve $\ln p - 1/T$ is a straight line, or: $\ln p = A - (B/T)$ (1), where $A = 7.8704$ and $B = 1921.4$. Baxter, *et al.* (*C. A.* 14, 2570), however, find A 8.2424 and B 2045.1, which suggests that (1) obtains only for a certain temp. range. Hertz's equation, $\ln p = \alpha - (\beta/T) - (\gamma \ln T)$, where $\alpha = 18.3014$, $\beta = 2485.5$ and $\gamma = 3.468$, covers the entire temp. interval from 0° to the b. p. and the calcd. results agree well with the exptl. ones. The b. p. of CCl_3NO_2 is calcd. to 112.21°. MARY JACOBSEN

Vapor pressure of toluene-cyclohexane mixtures. N. N. NAGORNOV. *Ann. inst. anal. phys. chem.* (Leningrad) 3, 584-92; *Chem. Zentr.* 1927, II, 2668; cf. *C. A.* 22, 4298.—The PhMe used b₇₆₀ 110.4°. For pure PhMe the following expression was found to be valid: $\log P = 7.06831 - 1409.9/(226.28 + t)$ (from 36 to 760 mm. of Hg). For the mixt. contg. 10.07% PhMe (by wt.): $\log P = 7.02006 - 1304.0/(233.07 + t)$; for the mixt. contg. 20.06% PhMe: $\log P = 6.95869 - 1277.0/(229.67 + t)$; for the mixt. contg. 40.06% PhMe: $\log P = 7.26319 - 1467.96/(248.21 + t)$; for the mixt. contg. 60.06% PhMe: $\log P = 7.25991 - 1492.2/(249.29 + t)$; for the mixt. contg. 79.97% PhMe: $\log P = 7.15982 - 1441.7/(239.05 + t)$. When the temp. is maintained const., the total vapor pressure increases progressively with the cyclohexane content. The partial pressures were calcd. by the empirical formula of Konovalov (*Z. physik. Chem.* 35, 129(1907); cf. *C. A.* 2, 619). The relative concn. of PhMe in the vapor is always less than in the liquid phase, while with every mixt. it increases with increase of temp. C. C. DAVIS

Change of state from liquid to vapor. H. I. CALLENDAR. *Engineering* 126, 594-5, 625-7, 671-3(1928).—C. gives a crit. discussion of the theoretical and exptl. contributions concerning the change liquid-vapor and reviews his own expts. carried out from 1886 onward, dealing mainly with water and steam. He detd. the ds. of water up to 380°, 6° above the crit. point at which the meniscus disappears. At 384 the d. of water was $\frac{2}{3}$ that of steam. The d. of steam could be measured up to 371°. At 380° both ds. become equal and the latent heat is zero. The expts. were performed with pure water in new quartz tubes. The results do not agree with van der Waals' equation, which requires that liquid and vapor curves should have a common tangent. The exptl. data show that the curves meet at an angle. C. checked these results by detg. total heats near the crit. point, using the method of condensing the steam in suitable app. The satn. lines for steam and water could be measured beyond 384°, where the meniscus vanished, nearly up to their junction at 380.5°. The satn. pressures were deduced from the measurements of the vols. of satd. water and steam and agreed (between 0° and 380.5°) with the formula: $\log p = A - (B/T) - C \log T + (kR/2) \log [(1+Z)/(1-Z)]$, where Z is a factor connected with C.'s coaggregation theory. This theory assumes that the change liquid-vapor is a mol. change such that in the liquid mols. of steam are dissolved while in the vapor there are complex (co aggregated) water mols. The dissocn. or formation of these co-aggregated mols. is assumed to be accompanied by a corresponding liberation or absorption of heat. H. S. VAN KLOOSTER

Measurements of the velocity of sound in air, nitrogen and oxygen, with special reference to the temperature coefficients of the molecular heats. W. G. SHILLING AND J. R. PARTINGTON. *Phil. Mag.* [7], 6, 920-9(1928).—The mol. heats of air, N_2 and O_2 were detd. at 0° to 1000° by a method depending on the measurement of the velocity of sound in the chem. pure gases. Further measurements for air up to 1300° are added, and a reply is given to criticism of the method of detg. the tube const. (*C. A.* 21, 1399 and *C. A.* 22, 1267). GEO. GLOCKLER

Thermal conductivity of carbon monoxide and nitrous oxide. H. GREGORY AND

C. T. ARCHER. *Proc. Roy. Soc. (London)* **A121**, 285-93(1928).—Measurements are described of the thermal cond. of CO and N₂O by the hot-wire method, details of the method being reported in earlier papers (cf. *C. A.* **20**, 1166). The cond. of both gases varies linearly with temp. between about 5° and 13°, the temp. range through which the measurements extend. The extrapolated values for 0° are 5.633×10^{-8} for CO and 3.740×10^{-8} for N₂O, and the respective temp. coeffs. 0.00317 and 0.00462. The factor f in the equation $K = fC_p\eta$, where K = thermal cond., C_p sp. heat at const. vol. and η the viscosity is 1.97 for CO and 1.70 for N₂O, C_p being calcd. from the measured C_p and γ . A detn. of the thermal cond. of air gave a mean value at 0° of 5.83×10^{-8} . While exptly. the viscosity of CO equals that of N₂ (1665×10^{-7}) and the viscosity of N₂O equals that of CO₂ (1366×10^{-7}) there is a material difference between the thermal conductivities of the members of these pairs; $K \times 10^7$ for CO, 563.3, N₂ 580; N₂O 374, CO₂ 360.4. W. WRST

Chemical reaction in the interferometer U-gage. CARL BARUS. *Brown Univ. Proc. Natl. Acad. Sci.* **14**, 939-43(1928).—The U-gage has shallow pools of Hg and each arm communicates with a Dewar flask contg. thermometer sensitive to 0.01°. P is introduced into one flask and both are closed. Temps. are read and the induced changes in level observed by the micrometer of the interferometer. The rate of absorption of O₂ after 16 min. drops to $\frac{1}{6}$, although only $\frac{3}{4}$ has been absorbed. A theoretical rise in temp. of 186° appears as only 1.4°, in consequence of loss of heat nearly as fast as it is liberated. In observing truly initial behavior there is no evidence of gas absorption but rather the increase in pressure on oxidation of P indicates the formation of an emanation. The initial rise in pressure is accompanied by a drop in temp. so that emanation is produced with a loss of heat. A. P. SACHS

Optical measurement of a small degree of dissociation of metal salt vapors. H. L. WYNEKEN. *Univ. Jena Z. physik. Chem.* **136**, 146-58(1928).—By photometric comparison of the intensity of the Hg absorption line 2536 in HgCl₂ vapor with the intensity of the same line in pure Hg vapor at known pressure, the degree of dissociation of HgCl₂ vapor at 200° is found to be 3×10^{-4} , agreeing with the value calcd. by the Nernst heat theorem. G. L. CLARK

Vapor pressures of fumigants. I. Methyl, ethyl, isopropyl and secondary butyl chloroacetates. O. A. NELSON. *Ind. Eng. Chem.* **20**, 1380-2(1928). The method of Smith and Menzies (*C. A.* **4**, 2595-6; **5**, 232) was employed. The vapor pressures of the chloroacetates were detd. for the following ranges of temp. Me, 20-135°; Et, 20-145°; isopropyl, 20-150°; secondary butyl, 20-170°. The following interpolation formulas, derived from Ramsay and Young's b. p. law as a basis, are valid: Me chloroacetate, $\log_{10}P = 8.4073 - (2222.2/T(\text{abs.}))$; isopropyl, $\log_{10}P = 8.3321 - (2298.6/T(\text{abs.}))$; Et, $\log_{10}P = 8.3893 - (2291.6/T(\text{abs.}))$; secondary butyl, $\log_{10}P = 8.3210 - (2393.44/T(\text{abs.}))$. Such equations do not hold very far beyond the b. p. By means of the fundamental equation, $PI = (x/M)RT$, the weight of fumigant that will vaporize into a 1000-l or a 1000-cu. ft. chamber can be calcd. A table shows these values for the temp. range 20-50°. **II. Methyl, ethyl, propyl, isopropyl, butyl, secondary butyl and isobutyl formates.** *Ibid* **20**, 1382-4. The vapor pressures of the formates were detd. as above for the following temperature ranges: Me, 20-32°; Et, 20-55°; Pr, 20-85°; iso-Pr, 20-70°; Bu, 20-110°; sec-Bu, 20-100°; iso-Bu, 20-100°. The equations developed are: Me, $\log_{10}P = 7.2203 - (1320.8/T(\text{abs.}))$; Et, $\log_{10}P = 7.8457 - (1621.6/T(\text{abs.}))$; Pr, $\log_{10}P = 7.9925 - (1806.5/T(\text{abs.}))$; iso-Pr, $\log_{10}P = 7.8909 - (1710.5/T(\text{abs.}))$; Bu, $\log_{10}P = 8.1232 - (1983.3/T(\text{abs.}))$; sec-Bu, $\log_{10}P = 8.0306 - (1888.9/T(\text{abs.}))$; iso-Bu, $\log_{10}P = 7.9060 - (1863.7/T(\text{abs.}))$. A table shows the wt. of fumigant necessary to sat. a 1000-l or a 1000-cu. ft. chamber. A. J. MONACK

Determination of the pressure and density of moist, saturated ammonium bromide vapor. ANDREAS SMITS AND RONALD PURCELL. *Univ. Amsterdam. J. Chem. Soc. (London)* **1928**, 2936-44, 2944-52. By means of the previously described densitometer, the vapor pressures and vapor ds. of NH₄Br were measured simultaneously between 332° and 395°. $\log p$ was found to be a linear function of $1/T$. It follows, then, that the latent heat of evaporation between 300° and 400° is not a function of the temp. The mol. heat of evapn. $(Q_{\text{H}_2\text{O}})_{\text{NH}_4\text{Br}} = 44 \times 10^3$ cal. was calcd. from the data. The vapor d. measurements as well as those made by an independent method, based on observations of the pressure of the satd. and of the unsatd. vapor of a weighed quantity of salt in a known vol., indicated that the vapor was completely dissocd. at 300-400°. The vapor pressures and vapor ds. of NH₄Cl were measured simultaneously between 254° and 353°. $\log p$ was found to be a linear function of $1/T$. It follows then that the heat of evapn. between 250 and 350° is not

a function of the temp. The mol. heat of evapn. $(Q_{80})_{\text{NH}_4\text{Cl}} = 39.6 \times 10^3$ cal., was calcd. from the data. From the derived vapor pressure formula the sublimation temp. was calcd. as 339.3° . The vapor d. measurements, as well as those made by an independent method, based on observations of the pressure of the satd. and of the unsatd. vapor of a weighed quantity of salt in a known vol., indicated that the vapor was completely dissociated at $250\text{--}350^\circ$. R. L. DODGE

Irrespirable atmosphere in the high Alpine mining district. GUSTAV HIESSLEITNER. *Montan. Rundschau* 26, 535-8(1928).—In certain districts about 1900 m. above sea-level, there are places where the atm. is irrespirable by human beings and where flames burn with great difficulty, or are put out. The phenomenon shows a max. intensity when the snow is rapidly melting. In each of these districts there are springs that deliver a very large vol. of water. It is suggested that the water of the springs and the water resulting from the melting of the snow are completely air-free and dissolve O_2 and N_2 from the air in the ratio of their solubilities multiplied by their partial pressures; i. e., about 1:2. Owing to this considerable absorption of O_2 the O_2 content of the air near such springs actually drops from 21 to 17%, a value too low for normal human life. After a time, diffusion counteracts the absorption of O_2 . A. L. H.

The approximate prediction of vapor pressure. JOHN CHIPMAN. Ga. School of Tech. *J. Phys. Chem.* 33, 131-5(1929).—For a given class of liquids there is a const. ratio between the apparent heat of vaporization, obtained by application of the Clausius-Clapeyron equation to vapor pressure data, and that given by the equation of Kistiakowski (*C. A.* 17, 3274). If the class to which a liquid belongs is known and the value of the ratio for that class is known, the approx. vapor pressure equation of the liquid may be estd. With the same data, a simple and reliable correction of the b. p. to normal pressure may be made. H. F. JOHNSTONE

The characteristic density and the properties of liquids. W. HERZ. Univ. of Breslau. *Z. anorg. allgem. Chem.* 175, 277-80(1928). Having found that $L/(d - d_K)$ where L is the heat of vaporization, d is the density at a given temp. and d_K the crit. density, is a const. for many liquids and that $\sqrt{L} \propto \sqrt{\eta}$ where η is the surface tension is also const. H. calcs. values for $\sqrt{\eta} \cdot (d - d_K)$ and finds const. for Et acetate, CCl_4 , C_6H_6 and even associated EtOH. The values of $\sqrt{\eta} \cdot (d - d_K)$ where η is viscosity, are const. for Me acetate, $\text{C}_6\text{H}_5\text{Cl}$, CCl_4 and octane. G. L. CLARK

A precision method for measuring temperatures of refractive index liquids on a crystal refractometer and on a microscope slide. F. W. ASHTON AND W. C. TAYLOR. *Am. Mineral.* 13, 411-8(1928). The method presented is of use in any microscopic work requiring the accurate measurement of temp. of single drops of liquids where η s are to be detd. to ± 0.001 . By using a differential thermocouple the temp. of the liquid can be measured with the desired accuracy, even when on a slide. The method differs in 2 essential points from that in common use: the location and protection of the thermometer, and the use of the thermocouple. A description of the app. and procedure is given. A. M. BRANT

The theory of the variation of refractive index with temperature measured in liquids by an interferometric method. GERHARD PETERS. *Ann. Physik* 86, 494-510(1928).—P. discusses the theoretical considerations in some detail, dealing not only with the formulas deduced by Newton, Dale and Gladstone, and Lorentz and Lorenz, but also with those obtained from thermodynamic considerations. A practical method is described using interferometer measurements on liquids, by means of which it is possible to obtain values of the η s at various temps. Results are given for HCN, the ds. being measured by means of a pycnometer. Refinement of this app. should lead to results which will allow of comparison of the measured and calcd. values. This comparison will give a true idea of the resp. values of the 3 formulas connecting d and η . G. L. CLARK

The influence of intensive drying on inner equilibria. III. ANDREAS SMITS. Univ. Amsterdam. *J. Chem. Soc.* 1928, 2399-409; cf. *C. A.* 22, 1523.—Baker's results on intensively dried liquids confirm S.'s theory of allotropy. Vapor density, rapid evaporation and distillation are "velocity" phenomena and large effects are to be expected from intensive drying, whereas vapor pressure is an equil. phenomenon and little or no effect should be observed. Surface-tension measurements are not trustworthy in the study of the change in properties of intensively dried systems. An elec. field has no influence when care is taken to prevent superheating. A. FLEISCHER

Theory of electrostriction and its experimental control. G. BRUHAT AND M. PAUTHENIER. *Compt. rend.* 186, 1289-91(1928).—The isothermal and adiabatic electrostrictions have been calcd. in terms of directly measurable quantities, and the agreement with the results obtained experimentally by means of the Lorentz-Lorenz

formula has been shown to be fairly good in the few cases for which data are available.
B. C. A.

Manipulation of the Engler viscometer. S. ERK. *Physik.-Techn. Reichsanstalt, Berlin. Erdöl Teer* 4, 583-4; *Chem.-Ztg.* 52, 995(1928); *Chem. Fabrik* 1928, 715-6.—The outflow vol. must be measured with flasks graduated for filling, cleaned and dried before each measurement, instead of graduated for delivery, draining 1 min. and using again, as sometimes practiced. The quantity of liquid remaining after draining 1 min. varies greatly, according to viscosity, introducing very appreciable errors. During the detn. temp. of the water bath must be held const. The drop in the thermometer reading, at the end of the detn., is due only to exposure of the thermometer bulb.

F. S. GRANGER

The theory of Brownian molecular motion. RICHARD GANS. *Ann. Physik* 86, 628-56(1928).—A detailed mathematical analysis.

G. L. CLARK

The Brownian motion of a wire. A. HOUDRIJK. *Arch. néerland. sci.* IIIA, 11, 212-77(1928).—A study was made of the movement of the lower end of a very fine suspended wire. The prepn. of very fine wires and the method of suspending them are described. The modulus of elasticity of very fine quartz threads probably is much less than 6000 kg./mm.², the value generally given. A formula is deduced for the mean longitudinal displacement of the end of the wire undergoing Brownian movement. Expts. with wires of various materials, lengths and diameters, suspended in various gases both at ordinary and reduced pressures were carried out. Results accord with calcd. values. The displacement is not influenced greatly by the gas in which the wire is suspended nor does change in pressure affect it greatly. The mean value calcd. for Avogadro's no. was 63.6×10^{23} . A rotatory Brownian motion was also observed and found to accord with theory.

RAYMOND H. LAMBERT

Diffusion of zinc in copper and in copper-zinc mixed crystals at 350°. Diffusion in the solid state. W. KÖHLER. *Zentr. Hütten- u. Walzwerke* 31, 650-7(1928).—Mean diffusion coeffs. are: Cu-Zn, 0.000033 cm. per day; α -brass-Zn, 0.000039 sq cm per day; β -brass-Zn, variable.

B. C. A.

Resistance and thermoelectric phenomena in metal crystals. P. W. BRIDGMAN. Harvard Univ. *Proc. Nat. Acad. Sci.* 14, 943-6(1928).—Summary of results of detailed paper to be published in *Proc. Am. Acad. Arts Sci.* An improved method of making rods of a single crystal of metal with varying orientations and an app. for measuring the thermal e. m. f. have been developed. 16 rods in which crystal orientation was the only variable factor were studied. The thermal e. m. f. between 20° and 88° of single crystals of Zn, Cd, Sb and Bi against Cu shows that the heat absorbed by an electron of Sb or Bi on changing its direction of motion from perpendicular to parallel to the axis is resp. 0.2 and 0.4 the energy of a gas mol. at same temp. The Kelvin-Voigt law for thermal e. m. f. is only approx. The failure of the K.-V. law is due to the Peltier heat as distinguished from the Thomson heat. The pressure coeff. of resistance of Sb and Bi was detd. over the entire range of orientation. From 3rd law of thermodynamics, the symmetry of the Peltier and the Thomson heat are the same and the apparent exptl. difference is due to greater error in measuring the Thomson heat. The local surface heat where current leaves a metal crystal is a function both of the direction of flow with respect to the crystal axis and of the orientation of the surface. Expts. offer no proof that electrons must move along fixed channels through crystals.

H. W. WALKER

The effect of gases on the resistance of granular carbon contacts. P. S. OLINSTEAD. Bell Telephone Labs., N. Y. *J. Phys. Chem.* 33, 69-80(1929).—A method is described whereby reproducible measurements of the resistance of C contacts can be made. The results show that when their surfaces are in equil. with the surrounding atm., the contact resistance between C granules increases with the gas pressure. The increase is reversible and is related approx. logarithmically to the pressure of the gas. At const. pressure, the increase in resistance diminishes as the temp. is raised. These facts suggest that the resistance of a granular C contact is detd., in part, by the amt. of gas adsorbed on the C surfaces. Furthermore, at const. pressure, the contact resistance decreases as the voltage is increased. This is due partly to the increased temp. of the contact. The evolution of gas entrapped in the pores opening on the area of contact causes an increase or decrease in the resistance, depending on the gas pressure surrounding the granules. After the voltage is increased to a certain value, depending on the kind of C used, there is a sudden decrease in resistance. This crit. voltage may be related approx. to the temp. at which further thermal decompn. of the granules begins. On the basis of this idea, if the amt. of combined H is a measure of the sp. resistance of the C, then the instantaneous resistance at the crit. voltage should

also be a measure of the resistivity of the C. The results indicate that there is a linear relationship between the resistance in ohms at this voltage and the percent H of compn.

H. F. JOHNSTONE

Reflective powers of some eutectic alloys in relation to their microstructures. G. ANDO. *Mem. Coll. Sci., Kyoto Imp. Univ. A*, 11, 43-84(1928); cf. Chikashige, *et al.*, *C. A.* 21, 1088.—The reflective powers of the binary alloys Ag-Cu, Cu-Cd, Cd-Sn, Cd-Bi, Bi-Sn have been investigated in their dependence on wave length and compn. The reflective power is usually minimal at the eutectic point. When, however, the reflective powers of the two components differ considerably, the min. tends to deviate toward the side of the weaker component.

B. C. A.

Optical properties of the highly refractive isostructural compounds of magnesium, calcium, strontium and barium with oxygen, sulfur, selenium and tellurium. M. HAASE. *Z. Krist.* 65, 509-87(1927).—The following n_s are recorded: MgO (d. 3.579 \pm 0.002), n_D 1.7366 \pm 0.001, n_{Ti} 1.7416 \pm 0.0005, n_C 1.7335 \pm 0.001; CaO n_D^{20} 1.838 \pm 0.002, n_{Ti} 1.845 \pm 0.003; SrO n_{355} 1.880, n_{570} 1.875, n_{800} 1.8675, n_{820} 1.863, n_{866} 1.8565 \pm 0.001; BaO n_{120} 2.002 \pm 0.001, n_{557} 1.989 \pm 0.002, n_{559} 1.980 \pm 0.001, n_{650} 1.960 \pm 0.004; the value for BeO increases with rise of the temp. of prepn. from the nitrate; MgS n_D 2.26 \pm 0.07; CaS n_{120} 2.161, n_{559} 2.137, n_{632} 2.124, n_{656} 2.120 \pm 0.002; SrS n_{510} 2.122, n_{570} 2.114, n_{595} 2.105 \pm 0.003, n_{656} 2.087 \pm 0.005; BaS n_D 2.155 \pm 0.005; MgSe n_D > 2.42; CaSe n_{555} 2.292, n_{559} 2.274, n_{620} 2.261, n_{656} 2.245 \pm 0.002; SrSe n_{540} 2.252, n_{565} 2.236, n_{589} 2.220, n_{620} 2.208, n_{656} 2.190 \pm 0.003; BaSe n_{560} 2.289, n_{589} 2.268, n_{620} 2.252, n_{675} 2.230; CaTe n_D > 2.51; SrTe n_D 2.408 \pm 0.004, n_C 2.367 \pm 0.005; BaTe n_D 2.440 \pm 0.005, n_C 2.379 \pm 0.003 (lattice constant a 6.82 \pm 0.02 A. U.).

B. C. A.

The refractive index of quartz. W. R. C. COODE ADAMS. *Proc. Roy. Soc. (London)* A121, 476-7(1928); cf. *C. A.* 22, 722.—The following equation is put forward for the extraordinary ray: $n^2 = n_\infty^2 + \Sigma[M_m/(\lambda^2 - \lambda_m^2)]$, where λ_m = the wave length corresponding to the natural frequency of an electron and M_m the corresponding refraction const. A table gives the calcd. and observed refractive indices of 18 lines in the visible and ultra-violet.

L. D. ROBERTS

Concerning Monel metal. I. Electrical and thermal properties and magnetostriction. ALFRED SCHULZE. *Z. Metallkunde* 20, 403-6(1928).—Nine specimens of Monel metal of several degrees of hardness were prep'd., both in the form of wire and in sheets. The sp. resistance at room temp. is approx. the same as that of manganin, varying from 42.63×10^{-6} for the softer specimens to 48.65×10^{-6} for the harder. The temp. coeff. of resistance varies from 1.66 to 2.12×10^{-3} , decreasing in general with increasing sp. resistance. Results are given for 2 samples at approx. 100° intervals from 0° to 600°. In both cases there is an abrupt change in the rate of change of resistance with temp. at approx. 100°. This is attributed to the change from the ferromagnetic to the paramagnetic state. The thermoelectric e. m. f. against Cu is the same for the 2 specimens, dE/dt being 29.0 microvolts per degree at 100° and 39.9 at 600°. For 2 specimens the coeffs. of expansion from 20° to 100° are 0.00001350 and 0.00001443, while from 500° to 600° the same specimens give 0.00001697 and 0.00001710, resp. The 2 "hard" specimens which were exam'd. for magnetostriction show no effect even in fields of 400 gauss. The 4 softer specimens all show a contraction which is approx. proportional to the applied external field for small values but in every case become approx. const. for all fields above a certain value, never greater than 25 or 30 gauss. The actual amt. of contraction varies between wide limits, being greatest for the specimen having the greatest Ni content. None of these specimens shows the after-effects reported by Williams (*Phys. Rev.* 29, 370(1927)).

W. W. STIFLER

Monel metal. II. Magnetization curves of Monel metal. A. KUSSMANN. *Z. Metallkunde* 20, 406-7(1928).—Results are given for a series of magnetic measurements on one of the samples studied by Schulze (cf. preceding abstract) of which the compn. is 65.8 Ni (trace of Co), 30% Cu, 1.9% Fe, 1.1% Mn, 1% Zn. When the metal is heated to 600° and cooled slowly the magnetization curve rises rapidly, the value of $4\pi J$ being 82 for a magnetizing force of 0.04 gauss, 1110 for 3.45 gauss and 1500 above 2750 gauss; the coercive force is 0.1 gauss and the initial permeability is approx. 1100. When quenched in H₂O from 600°, the curve rises more slowly, the value of $4\pi J$ for 3970 gauss being 850. The coercive force is 0.32 gauss and the initial permeability about 200. When annealed, for a magnetizing force of 50 gauss the value of $4\pi J$ decreases from 2600 at -79° to 155° at 58°. The results in general confirm earlier work by Barrows (*Elec. World* 78, 115(1921)). A discussion of the various factors affecting the magnetic behavior of alloys contg. Ni is included.

W. W. STIFLER

The crystallization and deliquescence of quaternary pyridine bases. G. D. SCHRIV.

J. Russ. Phys. Chem. Soc. **60**, 325-30(1928).—Crystals resulting from the action of PhCH_2Cl or PhCH_2Br on $\text{C}_6\text{H}_5\text{N}$ deliquesce and, when dissolved in EtOH , can be recovered only in the form of oily drops. The drops lose moisture and crystallize after 1-2 days over H_2SO_4 in a desiccator. The absorption of moisture from the atm. occurs with diminishing velocity. The max. amts. absorbed indicate the formation of the monohydrates of $\text{PhCH}_2(\text{C}_6\text{H}_5\text{N})\text{Cl}$ and $\text{PhCH}_2(\text{C}_6\text{H}_5\text{N})_2\text{Br}$, resp. A detailed description of the crystals is given.

BASIL C. SOYENKOFF

Magnetism of zirconium hydrate. F. BOURION AND (MLLE.) O. HUN. *Compt. rend.* **187**, 886-8(1928).—With a Curie balance, the magnetic susceptibility of $\text{Zr}(\text{OH})_4$ at various degrees of dehydration was measured. The ratio of magnetic susceptibility to that of H_2O was found to be a linear function of the H_2O content above 5% H_2O . Hence, from the magnetic point of view, $\text{Zr}(\text{OH})_4$ behaves like a mixt. of H_2O and the feebly paramagnetic hypothetical ZrO_2 . By extrapolation the susceptibility of ZrO_2 is found to be of the order of 0.4×10^{-7} .

W. W. STIFLER

Magnetic susceptibilities of single crystals of zinc and cadmium. J. C. MCLENAN, R. RUEDY AND ELIZABETH COHEN. *Proc. Roy. Soc. (London)* **A121**, 9-21(1928), cf. *C. A.* **22**, 1897.—An equation for magnetic susceptibility, based on the Pauli-Fermi theory is developed. From this it is deduced that the susceptibility should be independent of the temp. The effect of orientation on susceptibility is then discussed for crystals belonging to the hexagonal system. Full details of the method of prep. single crystals of Zn and Cd are given. The susceptibilities of these, for various orientations, were measured by Gouy's method. The susceptibilities parallel and perpendicular to the hexagonal axis are, resp., for Cd 190×10^{-6} and 145×10^{-6} ; for Zn 261×10^{-6} and 160×10^{-6} . Attempts also were made to prep. single crystals of Hg. The results with these seemed to indicate that the Hg was crystd. in the rhombohedral form.

W. W. STIFLER

Change in elastic properties on replacing the potassium atom of Rochelle salt by the ammonium group. W. MANDELL. *Proc. Roy. Soc. (London)* **A121**, 122-30(1928).—The method of prep. large crystals of $\text{Na}(\text{NH}_4)\text{C}_4\text{H}_4\text{O}_6 \cdot 4\text{H}_2\text{O}$ is described. The 9 elastic consts. and 9 elastic moduli were detd. for this salt in the same manner as for $\text{NaKC}_4\text{H}_4\text{O}_6 \cdot 4\text{H}_2\text{O}$ (*Proc. Roy. Soc.* **A116**, 623(1927)). In general the results are similar but, both for twisting and bending expts, the NH_4 salt is less elastic than the K analog. The elastic curves show slight differences, especially in the directions of max. piezoelec. response. While it is to be expected that the effects of replacing K by NH_4 would be largely masked in so complex a mol., the fact that the elastic properties are diminished in all directions suggests that the K must be a sort of "key" atom in the mol.

W. W. STIFLER

Determination of hydration from surface tension. H. FREUNDLICH AND A. SCHNELL. *Z. physik. Chem.* **133**, 151-64(1928).—The surface tension of aq. isoamyl alc. solns. contg. sugar or electrolytes at various concns. has been measured. Szyszkowski's equation is valid for the mixed solns. From the results the degrees of hydration of dextrose and sucrose and of a no. of Na and K salts have been calcd. The hydration of the anions corresponds with the lyotropic series. The calcd. values of the hydration are in agreement with those obtained by other workers from partition and solv. data, but for the Na and K cations the values deviate widely from those derived from mobilities; with the anions no such deviation exists.

B. C. A.

Electroosmosis and electrolytic transport of water in solutions of alkali chlorides. J. BABOROVSKÝ AND J. VBLÍŠEK. *Chem. Listy* **22**, 265-7(1928).—Measurements of the proportion of solns. of NaCl, KCl or LiCl transported by one faraday, of the electrolytic transport of water in these solns., of the transport of these salts themselves, and finally of the transport nos. of their cations in normal soln. show that these are linear functions of the concn. in g.-equivs. This confirms the work of Hephurn on other electrolytes (*C. A.* **21**, 202, 1742).

B. C. A.

Dipolar nature of adsorbed gas molecules. A. MAGNUS. *Z. Elektrochem.* **34**, 531-3(1928).—A theoretical discussion, based chiefly upon the behavior of CO_2 and H_2SiO_3 gel, and the Henry and van der Waals equations, leads to the conclusion that adsorbed gases are dipolar.

W. W. STIFLER

Magnetic properties of some substances in the adsorbed phase. S. S. BHATNAGAR, K. N. MATHUR AND P. L. KAPUR. *Indian J. Physics* **3**, 53-66(1928); cf. *C. A.* **22**, 4049.—Fe, Ni, Co and Mn lose their paramagnetism and become diamagnetic when adsorbed on charcoal. Adsorption is not analogous to mixing, but would appear rather as a chem. combination. Adsorption on SiO_2 increases the paramagnetism of Fe slightly.

ALBERT L. HENNE

Adsorption of the alkali metals on a mercury-vacuum interface. R. STEVENSON

BRADLEY. Univ. Leeds. *Phil. Mag.* [7], 6, 775-9(1928).—For the amalgams of the metals Na, K and Cs at low concns. $d\sigma/d(\log a_2)$, in which σ = surface tension, a_2 = activity of the dissolved metal, is const. Values of the surface excess, are in agreement with compd. formation in the surface-layer, roughly to the extent of Na-Hg for Na, rather less for K. Cs atoms alone occupy the surface of Cs amalgams. G. G.

The thickness of adsorbed vapor films. II. G. H. LATHAM. *J. Am. Chem. Soc.* 50, 2987-97(1928); cf. *C. A.* 21, 2585.—Measurements of adsorption by detg. the temp.-vapor pressure curves showed that, on plane surfaces of fire-glazed glass and of Ag covered with Hg, acetonitrile and MeNO_2 were adsorbed in layers only one mol thick. Thus polar compds. do not differ from non-polar ones in this respect (cf. *C. A.* 21, 2585). But if the glass is treated with acid, or if Pt-covered Ag is used, the adsorbed layers are, resp., 30-60 and 28-33 mols. thick, and similar results are obtained with non-polar compds. Conclusion: The glass treated with acid and the Pt covered with Hg do not present plane surfaces and polymol. adsorption occurs only on surfaces that are not plane. DON BROUSE

The phenomenon of molecular-ionic sorption. I. (1) Autosorption, (2) ionic sorption by means of a solution of nonelectrolyte. S. V. GORBACHEV. *Trans. Sci. Chem.-Pharm. Inst. (Moscow)*, 7 30(1925).—A review. J. S. JOFFE

A rapid method for the approximate determination of the sorption isothermals of vapors on charcoal. I. The principle of the method. A. J. ALLMAND AND J. E. MANNING. Univ. of London. *J. Soc. Chem. Ind.* 47, 369-72T(1928).—A complete and satisfactory evaluation of the relative sorbent properties of a set of activated charcoals can be based only on a full knowledge of the courses of their resp. isotherms. A rapid method of measuring adsorption isotherms was devised, based on measuring the rate of evolution of an adsorbed vapor into a current of air at 100° . The retentivity curves (wt of adsorbed vapor retained *versus* time) are similar to those obtained by evacuation of the charcoals. Plotting the slopes of these curves against the vapor contents of the charcoals gives curves bearing a striking resemblance to the isothermals for 25° . By suitable selection of a scale, values for adsorption vs. pressure can be obtained that show general agreement with those detd by direct vacuum method of adsorption measurements. **II. A working description of the simple retentivity test.** A. J. ALLMAND AND L. J. BURRAGE. Univ. of London *Ibid* 47, 372-6T.—A detailed description is given of the app. and method to be used in applying the retentivity test as a means of measuring adsorption on charcoals. The factors affecting the results, such as quantities of charcoal used, rate of air passage and satn. of the charcoal, were studied. R. L. DODGE

Sorption of carbon tetrachloride at low pressures by activated charcoals. Pt. I. Apparatus and method. RUFUS CHAPLIN. *Proc. Roy. Soc. (London)* A121, 344-58 (1928). A detailed description is given of the app. and technic by which the sorption isothermals of CCl_4 vapor on charcoal in the absence of foreign gases were detd. Pressures were measured by a Pirani gage, the calibration and method of use of which are fully described. The pressure range was 1×10^{-4} to 2.3×10^{-4} mm. Hg, pressures being fixed by immersing solid CCl_4 in const. temp. cooling mixts. The 25° isothermal was detd. directly, and a series of isosteres (pressure of CCl_4 as a function of temp. at const. quantity of sorbed material), were measured at higher temp. from which the isotherms at higher temps. could be obtained indirectly. It was noticed that CCl_4 vapor displaced gases from charcoal even after evacuation at 800° and reevacuation at 25° the presence of these gases greatly increased the time required to attain equil. between the charcoal and CCl_4 . Reversible effects were obtained only after the displacement of these gases by a large amt. of CCl_4 and subsequent evacuation. Exptl. results are promised in a subsequent paper. W. WEST

Adsorption of vapor on a quartz or a glass wall. ANDREAS SMITS. *J. Chem. Soc.* 1928, 2952-4. It has been affirmed and denied that adsorption on a plane, unetched, is in multimolecular layers (cf. *C. A.* 19, 3188; 20, 3367; 21, 1576, 2585; 22, 3560, 4299). Expts. with NH_4Br show that a layer 300 mols. thick is required to account for the adsorption. When a container is partly filled with a liquid or solid, mols. leave the liquid or solid phase and attach to the walls until the wall-phase is in equil. with the liquid or solid phase. This may require several layers of mols. As temp. is increased the number of adsorbed layers increases until all liquid or solid disappears. Further heating then decreases the number of adsorbed layers. F. E. BROWN

Adsorption of potassium chromate on zinc. R. F. REED AND S. C. HORNING. Univ. of Cincinnati. *J. Phys. Chem.* 33, 136-7(1929).— K_2CrO_4 reacting on Zn surfaces gives new properties by depositing a compd. of Cr. Studies on the adsorption of K_2CrO_4 on Zn and on the effect on the chem. reactivity of Zn indicate this compd.

acts as a strong poison for Zn catalysts. The compd. deposited is either ZnCrO_4 or K_2CrO_4 .

RAYMOND H. LAMBERT

The interaction of acids and neutral salts with stannic oxide and its relation to electrical charge. BHUPENDRA NATH GHOSH. Univ. Coll., London. *J. Chem. Soc.* 1928, 3027-38.—A study of the interaction of hydrated SnO_2 with electrolytes shows that the adsorption theory offers a better explanation of the observed facts than the chem. theory of insol.-salt formation; i. e., H ions are liberated by displacement from the double layer by the cations in soln. (cf. Mukherjee, *C. A.* 20, 1739). The α -oxide has a greater active surface per unit wt. than the β -oxide. The capacity of the cations for liberating H ions is in the order $\text{Mg} > \text{Ba} > \text{Sr} > \text{Li} > \text{Na} > \text{K}$. H ions are primarily adsorbed and the adsorption of an acid is greater, the less the pos. charge of the surface. The order of adsorption of acids is $\text{H}_2\text{PO}_4 > \text{H}_2\text{SO}_4 > \text{HCl} > \text{HNO}_3 > \text{C}_6\text{H}_5\text{SO}_3\text{H} > \text{CCl}_3\text{COOH}$. The greater the capacity of the anion for diminishing the pos. charge of the surface, the greater is the adsorption of the H ions. In the presence of salts with inactive cations, the adsorption of H ions is increased. Hence, salts with multivalent anions are more effective than those with univalent anions. The active surface varies nearly proportionately with the amt. of substance.

H. F. JOHNSTONE

Notes on dual emulsions, with examples of interest in the spraying of trees. ROWLAND M. WOODMAN. Horticultural Research Sta., Cambridge, Eng. *J. Phys. Chem.* 33, 88-94(1929); cf. *C. A.* 22, 4707.—Observations were made on some dual emulsions at the phase-vol. ratio used in spraying. The examples were petroleum ether-K oleate soln., emulsified in one expt. by vigorous intermittent shaking and in a second by gentle rotational shaking followed by vigorous shaking. Studies were then made with hydroxyl compds. of such types as the insecticide, ovicide, etc., emulsified with a soap soln. Stability of the emulsion depends on previous treatment of the container with one of the phases. The partition coeff. of a system should give valuable information and such studies are therefore being made.

RAYMOND H. LAMBERT

Application of the Fourier function to sedimentation. E. L. LEDERER. *Kolloid-Z.* 46, 173-6(1928).—Formulas were derived and tables calcd. for particle distribution at different levels and for different times during sedimentation of non-coagulating suspensions. The results agree well with Perrin's data. The formulas weaken Burton and Bishop's interpretation of Perrin's expts. The sedimentation equil. of dissimilar, large non-coagulating particles was calcd. for a detd. frequency distribution. L. F. MAREK

Application of the Fourier function to diffusion. E. L. LEDERER. *Kolloid-Z.* 46, 169-73(1928); cf. *C. A.* 22, 1884.—The Fourier function, unaided by other formulas, was used to calc. the diffusion coeff. from diffusion expts. carried out in the customary manner. Tables were calcd. which approx. closely those of Stefan-Kawalki. The coeffs. so detd. are larger than those calcd. from the Stefan-Kawalki tables and have the same value as the true coeff. when calcd. on the basis of other theoretical considerations such as ion mobility. L. F. MAREK

Effect of non-electrolytes on the stability of colloids. II. Ferric hydroxide sol. SUBODH GOBINDA CHAUDHURY AND ASHUTOSH GANGULI. Univ. Coll. of Sci., Calcutta. *J. Phys. Chem.* 32, 1872-4(1928); cf. *C. A.* 22, 4311.—The $\text{Fe}(\text{OH})_3$ sol was prepd. by peptizing freshly prepd. $\text{Fe}(\text{OH})_3$ with FeCl_3 and then dialyzing. MeOH, EtOH and pyridine sensitized the sol independently of the valence of the pptg. ions. Urea sensitized the sol toward KCl and K_2SO_4 ; glycerol sensitized it toward K_2SO_4 and $\text{K}_4\text{Fe}(\text{CN})_6$.

E. G. VAN DEN BOSCH

Ion antagonism in colloidal systems. I. Some rules on the ion effect in the coagulation of hydrophilic sulfur sols. W. A. DORFMAN. *Kolloid-Z.* 46, 186-98(1928).—In the coagulation of hydrophilic S sols opposing effects were noticed between pairs of coagulating ions. H ion was used as the first member of pairs of ions and the degree of antagonism followed the Schulze-Hardy rule. The effects on coagulation of a no. of metal ions paired with H ion were studied, and curves plotted for these combinations. Combinations of MgCl_2 , CaCl_2 and NaCl with HCl show a max. effect only 50% that of HCl . The curve for KCl differed considerably from that for NaCl . Dilm. of the sol decreased the opposing effects of the ions noticeably. The discharge of the sol reduces the degree of hydration. Two factors det. the stability of the colloid: the charge on the sol particle and the degree of hydration. The combined action of these 2 factors det. the degree of ion opposition. II. Influence of the anion on the opposing effect of cations in the coagulation of hydrophilic sulfur sols. *Ibid.* 198-201.—Substitution of H_2SO_4 for HCl caused the opposing effects of cations in the mixt. to increase. This effect was studied for the pairs: H_2SO_4 - NaCl , H_2SO_4 - MgCl_2 , H_2SO_4 - AlCl_3 . The effect of the anion on the pair H_2SO_4 - $\text{Th}(\text{NO}_3)_3$ was very noticeable. The

increase in opposition was noticed only when the anion of the first member of the pair was changed. The change of anion of both members or of the second member only caused a slight decrease in degree of opposition.

L. F. MAREK

Ionic equilibrium in colloidal solutions. H. D. MURRAY. Imperial Coll. of Sci. and Tech., South Kensington. *J. Phys. Chem.* 33, 138-42(1928).—Ionic equil. in colloidal solns. is treated from the standpoint of mass action. Adsorption of electrolyte on the particle surface followed by ionization of the adsorbed electrolyte gives rise to the charge on the particles. Consideration is given to the possibilities of an unsatd. particle surface, of a satd. surface where little change in ionization occurs and of repressed ionization. Stabilizers having an ion in common with the substance of which the particle is composed are most efficient.

RAYMOND H. LAMBERT

The use of tartaric acid in the synthesis of electronegative sols. III. Adsorption of sodium tartrate and sodium succinate by aluminum hydroxide. A. DUMANSKII AND A. YAKOVLEV. *Bull. soc. chim.* 43, 969-77(1928); cf. *C. A.* 22, 4308.—A general method for prepg. negative hydrosols of heavy metal hydroxides is described which is based on the reaction between an acid-alc., an alkali and the hydroxide of a metal. The primary products of varying compn. are transformed slowly into the hydroxide of the metal either as a sol or a gel. Solns. of Na tartrate and succinate of varying strength were shaken with: (1) hydrosol of $Al(OH)_3$ prepd. by the reaction of $Al(NO_3)_3$ & $(NH_4)_2CO_3$; (2) freshly pptd. $Al(OH)_3$; (3) $Al(OH)_3$ four months old. Both salts were adsorbed by the $Al(OH)_3$, but the tartrate was adsorbed more than the succinate; (1) adsorbs more than (2), and (2) more than (3). With concd. solns. (6.5 to 0.8 *N*) there is $Al(OH)_3$ formed, in greatest amt. with (1) and least with (3). The addn. of either salt increases the surface tension of H_2O slightly.

E. G. VAN DEN BOSCHE

The dielectric constants of silver sols when diluted with varying amounts of ethyl alcohol. GEORGE D. ROCK AND SIMON KLOSKEY. Catholic Univ. of Am. *J. Phys. Chem.* 33, 143-7(1929).—Dielec. consts. of $EtOH-H_2O$ mixts. with and without Ag sol suspension were measured by means of high-frequency oscillators of the vacuum-tube type. The app. is described. Dielec. consts. of Ag sols were found to be essentially the same as those of the dispersion media.

RAYMOND H. LAMBERT

The coalescence of an unfilterable precipitate of barium sulfate. H. M. TRIMBLE. Okla. Agr. and Mech. College. *Proc. Oklahoma Acad. Sci., Univ. Oklahoma Bull., New Series No. 409, Studies Series No. 29*, 197(1928).—The coalescence of $BaSO_4$ ppt. on digestion which renders them filterable cannot be explained by growth of large particles at the expense of smaller ones. Apparently there is a collection of particles into larger aggregates, followed by cementation of the unit particles in the aggregates.

RUSSELL C. ERB

The coagulation of highly solvated sols by organic liquids and salts. II. B. JIRGENSONS. *Kolloid-Z.* 46, 114-28(1928); cf. *C. A.* 22, 4312.—The coagulation of casein, hemoglobin and egg albumin sols by $MeOH$, $EtOH$, $PrOH$ and ethyl urethan was studied in the presence of inorg. salts. At low concn. of both the org. liquid and the salt, coagulation in the mixt. is more rapid than in the presence of either the salt or org. liquid alone. At higher concn., i. e., 50% by vol. of $PrOH$ or 0.3 mol./l. of $CaCl_2$, the sols were stabilized. At still higher concn. the sols were coagulated. Glycerol sensitized casein sols to $MgCl_2$ at all concns. Sensitization is considered as caused by dehydration of the micelles and change in dielec. const. of the medium by the org. liquid. Stabilization is due to the peptizing action of the salt.

J. G. McNALLY

Spectrophotometric and cataphoretic experiments on the absorption of methylene blue chloride by gelatin. A. FODOR AND KURT MAYER. *Kolloid-Z.* 46, 201-7(1928).—Qual. expts. by cataphoretic, spectrophotometric and diffusion methods were carried out to discover if adsorption of the dye by gelatin is observable. The cataphoretic expts. indicated that gelatin adsorbs amts. of dye which change the charge on the gelatin at certain concns. Diffusion of the dye in gelatin gels contg. different salts gave rise to ring formation in alk. and neutral conditions but not in acid condition. The spectrographic method showed a significant adsorption at $pH = 4.8$. Quant. expts. were by the diffusion method and an attempt to evaluate the factors influencing the effects observed.

L. F. MAREK

The origin of concentration differences in dissolved substances opposed to the osmotic pressure in gelatin. RUDOLF AUERBACH. *Kolloid-Z.* 46, 321-3(1928).—Physicochem. studies in biology produce examples of concn. differences apparently in opposition to osmotic pressure. Using Congo red dye solns. over gelatin solns., A. attempts to explain this on the basis of the combined action of diffusion and adsorption and graphically illustrates the concn. differences obtained. Future work is intended with other dyes.

L. F. MAREK

A survey of the field of colloidal gels. WO. OSTWALD. *Kolloid-Z.* **46**, 248-67 (1928).—Previous attempts to classify gels are discussed. It is proposed to classify them by method of formation as follows: gels made by (1) lowering the soly., (2) chem. reaction, (3) coagulation, (4) swelling, (5) fermentation, (6) bacterial action, (7) mixing org. substances, (8) geologic processes. There are often many sub-types. Systems related to gels include supercooled melts, supercooled and supersatd. solns, concd. dispersions of solid in fluid, and concd. dispersions of gas in liquid. Distinction is made between lyophilic gels and desolvated gels and examples of each class are given. Phenomena of gelatinization are discussed in detail; the main characteristics of gelatinization are the immobility of the liquid phase with respect to the entire system, and the surface area of the solid phase, the cessation of Brownian movement, progressive sepn. into component parts and flocculation. No general swelling theory can be given because different gels possess different swelling factors. Thermodynamic considerations point to a neg. temp. coeff. of swelling but expt. proves it to be strongly pos. The different ways of destroying gels by drying, crystn., coagulation, liquefaction, etc., are discussed briefly. L. F. MAREK

The constitution and the stable condition of hydrogels. A. SIMON. *Kolloid Z.* **46**, 161-9 (1928).—The double role of the water in a gel is discussed in the light of different theories and expts. Water is present both in the capillary pores of the gel and as water of constitution. Much experimentation has been done on the detn. of the water of constitution with conflicting results. Correctly produced metal hydroxides which are amorphous hold the water by osmotic pressure. Crystn. marks a change from free or osmotically held water toward chemically held water. The primary product of an amorphous metal oxide hydrate changes with time to a crystn. stable compd. which is either an anhydride or a stoichiometric hydrate with the potential energy at a minimum. L. F. MAREK

The behavior of nitrocellulose gels in polarized light. A. J. PHILLIPS. Georgia School of Tech. *J. Phys. Chem.* **33**, 118-30 (1929).—Nitrocellulose gels prepd. in various ways were studied in polarized light under the microscope. The color observed both with crossed nicols and by a gypsum plate together with crossed nicols is tabulated for the many samples examd. The color in polarized light is a function of the dispersion of the nitrocellulose. It is influenced by the proportion of H_2O and the ratio of HNO_3 to H_2SO_4 in the nitrating bath, by treatment to reduce viscosity, by ultra-violet light, by heat and by superheating the water. The degree of nitration is of less importance in this respect than the degree of dispersion. As the latter decreases the color of transmitted light ranges from red to blue. RAYMOND H. LAMBERT

Solubility relationships of lactose-sucrose solutions. I. Lactose-sucrose solubilities at low temperatures. PHILIP N. PETER. U. S. Dept. of Agr. *J. Phys. Chem.* **32**, 1856-64 (1928).—The soly. of lactose in H_2O and in sucrose solns. of varying concn. was detd. at 0° and at -3° . The soly. of lactose was also detd. in glucose solns. The soly. of lactose in nearly satd. sucrose solns. is reduced to about one-half of its value in H_2O . Consequently, in ice cream the H_2O may be greatly supersatd. with respect to lactose. Because of the high viscosity of the medium it may require several weeks or even months for crystn. The presence of lactose has but a slight effect upon the soly. of sucrose. E. G. VAN DEN BOSCHE

Solubility. XI. Solubilities of liquid stannic iodide in several liquid paraffins. MIRIAM E. DICE AND J. H. HILDEBRAND. *J. Am. Chem. Soc.* **50**, 3023-7 (1928); cf. *C. A.* **21**, 1578.—Because of its high internal pressure SnI_4 is incompletely miscible with liquid paraffins. The critical mixing temps. were observed in mixts. contg. increasing mol. fractions of SnI_4 by heating the mixt. in a sealed glass tube. Mol. fraction-temp. curves are plotted for mixts. with *n*-octane, *n*-heptane, *n*-hexane and iso-octane, the maxima of which are the critical mixing temps. Critical mixing temps. agree well with relative internal pressures as calculated by Hildebrand's equation (Hildebrand, "Solubility," Chem. Catalogue Co., New York, 1924, p. 198). The critical mixing temps. probably represent the true order of internal pressures more accurately than heats of vaporization. The order of increasing internal pressure is the same as the order of increasing mol. wt.; *n*-octane is higher in internal pressure than iso-octane. An expression is proposed which fits the liquid-liquid solubility curves. D. B.

Solubility of sodium benzenesulfonate in water and in solutions of sodium sulfate. F. H. RHODES AND A. W. LEWIS. Cornell Univ. *Ind. Eng. Chem.* **20**, 1366-7 (1928).—The soly. of NaO_3SPh in water, in g. of salt per 100 g. of soln. is 26.8, 35.8, 37.4, 38.0, 40.4, 41.9, 45.1, 48.0, 49.4, 51.1, 58.5, resp., at 0° , 30° , 35° , 40° , 45° , 50° , 60° , 70° , 75° , 80° , 105° . A soln. of $5Na_2SO_4 + 95H_2O$ dissolves 32.2 g. sulfonate at 30° , 38.6 g. at 50° and 45.2 g. at 70° . At the same temps., the solubilities in $10Na_2SO_4 + 90H_2O$ are

resp.: 27.7, 34.4 and 42.1; in $20\text{Na}_2\text{SO}_4 + 80\text{H}_2\text{O}$, they are resp.: —, 25.8 and 31.9. At relatively low temp. the salt crystallizing out is the dihydrate. The temp. of transformation of this dihydrate to the anhyd. form is 66.8° , as detd. with a dilatometer.

ALBERT L. HENNE

Note on the ebullioscopic method of molecular-weight determination. HIKOICHI SHIBA AND TOSHIKAZU IMASE. *Bull. Inst. Phys. Chem. Research* (Tokyo) 7, 996-8(1928), *Abstracts* 1, 96.—An improved form of Cottrell's app. was constructed to det. accurately the mol. wt. in soln. The funnel-shaped part was changed to a double wall which always contained the vapor phase to facilitate boiling. The b. p. elevation was measured within 0.001° with a Beckmann thermometer. The mol. wt. of cane sugar was detd. accurately in as little as 2.5 cc. of soln.

ALBERT L. HENNE

The apparent hydration of ions. II. The densities and viscosities of some mixed aqueous solutions of lithium chloride and hydrochloric acid. JOHN W. INGHAM. Heriot-Watt College, Edinburgh. *J. Chem. Soc.* 1928, 2381-8; cf. *C. A.* 22, 4034.—The methods for measuring densities and viscosities were those previously described. The hydration of the ions decreases according to the series Li, Na, K. The decrease in viscosity upon replacing LiCl by HCl is due to the relatively small hydration of H ion. An equation of the type $d = K + k_1a + k_2b$ represents the density data fairly well. In the LiCl-HCl system the greater free space is counterbalanced by the increased hydration of the Li ion.

ARTHUR FLEISCHER

The viscosity of supersaturated solutions. II. I. K. TAIMNI. Univ. College, London. *J. Phys. Chem.* 33, 52-68(1929); cf. *C. A.* 22, 2095.—The effect of change of temp. and concn. on the viscosity of concd. solns. of sucrose, urea, AcNH_2 , citric acid and $\text{Na}_2\text{S}_2\text{O}_7$ in H_2O and of resorcinol, AcNH_2 and urethan in EtOH, and of phenylthiurene and urethan in MePh, in the neighborhood of their resp. soly. temps. was detd. The relations between viscosity and concn. can be represented by 1 of the equations: $\log \eta = \theta c + \phi$, or $\eta = mc + n$, where θ , ϕ , m and n are consts. For the systems, the viscosity may be represented as a function of temp. and concn. $\log \eta' = (kt + k')c$. Here η' is the relative viscosity and k and k' are consts.

H. F. JOHNSTONE

Distribution of ammonia between water and chloroform at 25° . HAROLD G. ETRICH. Yale Univ. *J. Phys. Chem.* 33, 95-8(1929).—The distribution of NH_3 between H_2O and CHCl_3 was detd. at 25° for three stock samples of CHCl_3 . Two of these gave mean coeffs. of distribution of 35.82 and 35.83 m_w/m_c . The third was slightly lower, perhaps because of traces of impurity inhibiting hydrolysis of CHCl_3 . Discrepancies in the coeffs. given in the literature may be due to the same cause.

RAYMOND H. LAMBERT

The ionization of aromatic nitro compounds in liquid ammonia. II. WILLIAM GARNER AND HENRY F. GILLBE. University College, London. *J. Chem. Soc.* (London) 1928, 2889-904; cf. *C. A.* 19, 2588.—The velocity of ionization in solns. of dinitrobenzene and of *m*-dinitrotoluene in liquid NH_3 was found to follow a first-order law, even in those cases where the ionization did not go to completion. The mic concns. were detd. by measuring the extinction coeffs. of the colored solns. The mic concn. at any time was found to be proportional to the cond. The most probable course of the reaction is $\text{R}(\text{NO}_2)_2 + 2\text{NH}_3 \rightleftharpoons \text{R}(\text{NO}_2)_2 \cdot 2\text{NH}_3 \rightleftharpoons \text{R}(\text{NO}_2)_2^{--} + \text{N}_2\text{H}_5^{+}$, the velocity of the reaction being governed by the first step. The color is very probably due to the org. anion $\text{R}(\text{NO}_2)_2^{--}$. The temp. coeff. is that of ordinary chem. reactions. The calcd. crit. increment is 7520 cal. No evidence was obtained of the existence in the solid state of complexes such as $\text{R}(\text{NO}_2)_2 \cdot x\text{NH}_3$.

R. L. DODGE

The average activity coefficients of the hydrogen and bicarbonate ions in potassium chloride and concentrated sodium chloride solutions, and the dissociation constants of several indicators in these solutions. E. GÜNTHERBERG AND E. SCHÖDT. Techn. Hochschule, Kopenhagen. *Z. physik. Chem.* 135, 393-443(1928).—From measurements with the quinhydrone electrode the av. activity coeff. for H^+ and HCO_3^- ions $\sqrt{a_{\text{H}^+}a_{\text{HCO}_3^-}}$ and the apparent first disson. const. of H_2CO_3 , $K_c = C_{\text{H}_2\text{CO}_3}/C_{\text{CO}_2} + C_{\text{HCO}_3^-}$, in 0.1 to 3 *N* KCl and in 3, 4 and 5 *N* NaCl solns. are detd. K_c behaves as the disson. const. of other weak acids; it rises from 3.2×10^{-7} in pure H_2O to about three times as much in *N* KCl and again decreases: in satd. NaCl the value is only about 30% higher than in pure H_2O . The statements of Szyzskowski and Wilke that H_2CO_3 in strong salt solns. is more than 100 times stronger as an acid than in H_2O are erroneous since they have used several of the classical laws applying only to very dil. solns. for the entire transition to very concd. salt solns. without correcting for the change in the soln. medium (e. g., activity coeff.). The disson. const. of Me orange,

bromophenol blue and dimethyl yellow are detd. in the same solns. in which the values for H_2CO_3 were obtained. A characteristic but natural difference in the variation of the acid dissocn. const. of a nonelectrolytic acid, a univalent cation and a bivalent ion in the presence of salts is observed. The av. activity coeff. and dissocn. const. of benzoic acid are measured in 3 *N* KCl and 3, 4 and 5 *N* NaCl. The benzoate ion has an extraordinarily high activity coeff. while HCO_3^- has a very small one. Several observations are made on the "salt-error" in colorimetric p_{H} measurements and the relative magnitudes of ion activity coeffs. in strong uni-univalent salt solns. bearing on the work of Harned and Åkerlöf.

G. L. CLARK

Methods of determination of hydrogen-ion concentration, and applying such methods in sugar manufacture. I. A. KUKHARENKO AND B. G. SAVINOV. *Monograph on the sugar industry* (Russian, with summary in English) 1928, 11-147.—The literature on the electrometric and colorimetric detn. of p_{H} in general, and on the special applications in the sugar industry is reviewed comprehensively. The results obtained are often contradictory, and no definite conclusions can be drawn as yet, but the subject merits intensive methodological study.

F. W. ZERBAN

The behavior of the antimony electrode in buffered and unbuffered solutions. V. G. LAVA AND E. D. HEMEDES. Univ. of the Philippines. *Philippine Agr.* 17, 337-49(1928).—Sb electrodes were tested in buffer solns. of KH_2PO_4 and NaOH and in mixts. of 0.01 *N* NaOH and 0.01 *N* HCl at 26-29°. By use of the equation $E = 0.052 + 0.057 p_{\text{H}}$, the p_{H} of such solns. may be satisfactorily detd. In sugar solns $E = 0.052 + 0.057 p_{\text{H}}$. Since the Sb electrode is mechanically sturdy, cheap, gives quick responses, has a wide range of p_{H} values at which it gives accurate results and requires little care, it is recommended for continuous reading of p_{H} in sugar juice during clarification. The Sb electrode may also be used for centrifugal sugar, molasses and soils. Unexplained errors occur, however, when used for soils.

A. L. MEHRING

p_{H} Measurement with the glass electrode and vacuum tube potentiometer. L. W. ELDER, JR. AND W. H. WRIGHT. Univ. of Ill. *Proc. Nat. Acad. Sci.* 14, 936-9 (1928).—Oxidizing agents, Pt poisons and other substances catalytically decompd. by Pt and for which ordinary H or quinhydrone electrodes are inapplicable may be titrated electrometrically, but only 2 methods are sufficiently reversible and reproducible to serve for p_{H} measurement, i. e., the Sb_2O_3 and glass electrodes. The glass electrode has the wider application but has required a quadrant electrometer, which is affected by atmospheric conditions and involves other difficulties. E. and W. find a vacuum tube potentiometer with Type UX222 tube very satisfactory. The wiring and method of reading are given. Operation is much simpler than with a quadrant electrometer.

A. P. SACHS

The potential of solutions of glucose. RENE WURMSER AND JEAN GELOSO. Institut de Biologie physicochimique, Paris. *J. chim. phys.* 25, 641-57(1928); cf. *C. A.* 21, 1467; 22, 3343.—The oxidation-reduction potentials of 0.016 *M* glucose solns in the presence or absence of dyes, in 0.1 *M* phosphate buffers at temps. from 40° to 91° and p_{H} range of 6.5 to 11 is expressed by the equation: $E_{\text{H}} = -0.00020 T p_{\text{H}} - 0.00088 T + 0.50 \pm 0.02$. The results confirm previous publications.

A. F.

The new law of mass action. VI. The possibility of exchange of components within the limits of the equation of the new mass-action law. RICHARD LORENZ Frankfurt. *Z. anorg. allgem. Chem.* 175, 257-69(1928); cf. *C. A.* 23, 23.—A complex mathematical analysis is made of the law $[x/(1-x)][(1-y)/y] = Ke^u$,

$$u = (\alpha/RT) \left\{ \frac{x^2 - [(1-x)^2/(1+r)]}{(1+rx)^2} \right\} - (\alpha'/RT) \left\{ \frac{y^2 - [(1-y)^2/(1+r')]}{(1+r'y)^2} \right\},$$

where α and r are the const. a and b of van der Waals' equation. The typical example is

in terms of molar thermodynamic potential.

G. L. CLARK

Keto-enol isomerism and the mechanism of homogeneous reactions. F. O. RICE AND J. J. SULLIVAN. *Trans. Faraday Soc.* 24, 678-82(1928).—The rate of the keto-enol change of acetoacetic ester was detd. The const. for the rate of reaction varied considerably with the particular fraction of enolic distillate used. Acetyl chloride, carbonyl chloride and phthalic anhydride proved to be accelerators rather than stabilizers for the change. The order piperidine, NH_3 , Br, pyridine, quinoline is that of decreasing activity for these substances toward the change. It is suggested that the change takes place through a unimol. mechanism, the enolic form or a complex thereof with the catalyst undergoing a unimol. decompn.

P. H. EMMETT

The behavior of butyl bromide at its transformation. GEORGES DIENGER. Techn. Hochschule Zürich. *Z. physik. Chem.* 136, 93-134(1928).—The velocities of transformation of isobutyl bromide into tertiary butyl bromide and *vice versa* are measured at several temps. from 178.5° to 240°. The discovery of Michael that with respect to the equil. point the velocity of transformation of the tertiary bromide is much too small is substantiated. In the neighborhood of equil. there is a region in which the reaction velocity is too small to detect. This is reached only from the side of the tertiary bromide. G. L. CLARK

Oxidation of ferrous hydroxide in sodium hydroxide solution by means of air. S. MIYAMOTO. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) 9, 203-8(1928); cf. *C. A.* 22, 3566.—The velocity of the oxidation of Fe(OH)_2 by air is independent of the amt. of Fe(OH)_2 present. The velocity const. is almost the same as for the oxidation of Na_2SO_3 and Sn(OH)_2 under the same conditions. The effect of temp. is slight. NaOH decreases the velocity of oxidation because the velocity of oxidation is nothing but the velocity of solution of O_2 under the given conditions, which is decreased by NaOH. ALBERT L. HENNE

Equilibrium between methanol, carbon monoxide and hydrogen. DAVID F. SMITH AND BRIANT F. BRANTING. Pittsburgh Expt. Sta. *J. Am. Chem. Soc.* 51, 129-39(1929).—The equil. $\text{CH}_3\text{OH}/(\text{CO})(\text{H}_2)^2$ at 1 atm. over ZnO and the 4Zn:1Cr catalyst of Smith and Hawk (*C. A.* 22, 1520) was studied by a direct method giving $K = 5.57 \times 10^{-4}$ at 303.8°, error $\pm 5\%$. From this equil. value and the heat data of S. (*C. A.* 21, 2783), the free-energy change is $\Delta F = -20,857 + 41.17 T \log T - 6,01123 T^2 - 54.42 T$, giving 16,070 Cal. at 700° K. A. S. CARTER

Relationship between velocity of hydrolysis by alkali and structure of esters. H. OLSSON. *Z. physik. Chem.* 133, 233-52(1928); cf. *C. A.* 21, 1581.—A no. of esters have been prep'd. in a pure state and their rates of hydrolysis in presence of alkali measured. The velocity coeffs. of the hydrolysis of some 85 typical esters, given in the literature, have been reduced to the same units and the results compared from the same point of view of structure. The velocity coeff. is mainly influenced by the strength of the acid component of the ester, but in other cases steric hindrance influences the locity in the opposite sense. It may be that these 2 influences are manifestations one fundamental property, *viz.*, the force of dissoen. of the sep. components. B. C. A.

Homogeneous catalysis. C. N. HINSHELWOOD. *Trans. Faraday Soc.* 24, 552-9(1928).—The present status of our knowledge of the mechanism of activation in homogeneous, uni-, bi- and tri-mol. reactions is outlined. In 87 papers dealing with the effect of traces of moisture upon reaction rate the oxidation of NO by O_2 is the only homogeneous gaseous reaction proceeding at a reasonable rate that is affected by moisture. Even in this case there is exptl. uncertainty. It is suggested that water vapor influences the rate of reaction only in that type of homogeneous gaseous reaction that may be termed "uncontrollable," in which the rate is either zero or immeasurably great. A summary of the influence of foreign gases on homogeneous gaseous reactions indicates that the effect depends upon the sp. transfer of energy from mols. of the reactants to those of the inert gas. P. H. EMMETT

Some problems in homogeneous catalysis. T. M. LOWERY. *Trans. Faraday Soc.* 24, 545-51(1928).—A review of modern theories of homogeneous catalysis and an outline of the problems now being attacked by various workers. P. H. EMMETT

Investigations of salt action in homogeneous catalysis. HERBERT S. HARNED AND GOSTA ÅKERLÖF. *Trans. Faraday Soc.* 24, 666-78(1928); cf. *C. A.* 22, 715.—It is futile to try to use the individual ion activity coeff. of the catalyst ion. If the catalyst is a weak electrolyte whose dissoen. const. is known, the primary and secondary salt effects can be conveniently sep'd. Study of the primary salt effect in more than 6 reactions fails to reveal any simple generalization. The distribution of the effects of the salts is different in each reaction. The addn. of a salt in acid catalysis usually tends to increase the reaction velocity while in hydroxide catalysis the reverse is usually, but not always the case. Data are presented for the numerous systems in which the primary salt effect was studied. P. H. EMMETT

Acid and salt effects in catalyzed reactions. XVII. Variation of the catalytic activity of an acid with its concentration and the determination of ionization constants. HARRY M. DAWSON, GEORGE V. HALL AND ARTHUR KEY. *J. Chem. Soc.* 1928, 2844-53; cf. *C. A.* 22, 3338, 3339, 4333.—"The catalytic effects produced by propionic, acetic, succinic, β -chloropropionic, glycolic and chloroacetic acids have been studied with reference to the variation of the catalyzing power with the concn. It is shown that the connection between the reaction velocity and the concn. affords a means

of detg. the ionization const. of the acid as well as the catalytic activity of the undissocd. acid. The ionization const. derived from the catalytic data are in close agreement with those afforded by the elec. cond. of dil. solns. of the acids. In general, the catalytic activity of the undissocd. acid increases with the ionization const. The relation between the catalytically detd. const. K and the thermodynamic const. K_a is considered in reference to the various factors which affect the value of K under the conditions which obtain in the exptl. detns."

P. H. EMMETT

Catalytic effects of acids and bases and the influence of inert salts. H. M. DAWSON. *Trans. Faraday Soc.* 24, 640-51(1928); cf. *C. A.* 22, 3338, 4333.—Recent investigations have shown that the catalytic effects produced by acids cannot be interpreted in terms of H ions, OH ions, H_2O mols. and inert salt effects alone. The activity both of the unionized acid and of the acid anion must be taken into account. In general the entire catalytic relations in acid salt mixts. can be represented by a series of juxtaposed catenaries, the combination of which gives rise to a catenary surface in space defined by coördinates which correspond, resp., with reaction velocity, H-ion concn. and concn. of the catalyzing acid. There are 2 distinct effects involved in the action of the catalytically inert salts, (1) an increase in the activity of the H ion and (2) a change in the ionization const. of the acid. The first of these effects increases continuously with the salt concn., while the ionization const. increases to a max. value and then decreases. Catalytically inert salts do not, however, affect the nature of the relations which find expression in the sym. catenary curves as applied to weak acids.

P. H. EMMETT

The theory of acid and basic catalysis. J. N. BRØNSTED. *Trans. Faraday Soc.* 24, 630-40(1928); cf. *C. A.* 22, 4323, 4334.—The way in which recent studies have altered and extended the original Arrhenius interpretation of acid and basic catalysis is reviewed and B.'s comprehensive theory is presented. It rests fundamentally upon the definition of an acid as a compd. which can lose a proton, and of a base as a compd. which can add a proton.

P. H. EMMETT

The kinetics of acid and basic catalysis. ANTON SKRABAL. *Trans. Faraday Soc.* 24, 687-96(1928); cf. *C. A.* 21, 3798.—From the kinetic point of view 2 types of unstable intermediate compds. can be postulated: the Arrhenius type, which is in chem. equil. with the initial materials in that the rate of decompn. is slow compared to the rate of formation of the intermediate, and the "van't Hoff type," which is not controlled by this equil. and in which the rate of decompn. of the intermediate is high compared to its rate of formation. The intermediate complexes postulated by Lowry's theory are of the van't Hoff type.

P. H. EMMETT

Determination of the catalytic coefficient of the hydroxyl ion in the mutarotation of glucose and lactose. THOMAS M. LOWRY AND GORDON L. WILSON. *Trans. Faraday Soc.* 24, 683-7(1928); cf. *C. A.* 22, 722.—The catalytic coeffs. of OH ion in the mutarotation of glucose, lactose and tetramethylglucose were found to be 8000, 5000 and 1600, resp. "The wide variation in the value of this const. in sugars which are so closely related to one another, and which undergo mutarotation with very similar velocities in water is a noteworthy result of the research."

P. H. EMMETT

Ionization in chemical change. N. R. DHAR. *Trans. Faraday Soc.* 24, 565-7(1928); cf. *C. A.* 12, 111; 15, 2028; 16, 1691; 18, 3520.—The ions and electrons shown by various authors to be formed by exothermal chem. reactions are suggested by D. as activators for the reacting constituents in 4 types of chem. change (1) induced reactions—as in the reduction of $HgCl_2$ by $H_2C_2O_4$ in the presence but not in the absence of a drop of $KMnO_4$, (2) influence of moisture on chem. change—the water vapor tending to form clusters with the electrons and ions thus decreasing the chemiluminescence and after-glow of gases and (4) abnormal photochem. yields, the decompn. of H_2O_2 and of HCl being given as examples.

P. H. EMMETT

The influence of nitrogen peroxide on the union of hydrogen and oxygen. A problem of "trace catalysis." C. H. GIBSON AND C. N. HINSHELWOOD. *Trans. Faraday Soc.* 24, 559-62(1928).—The effect of small quantities of NO_2 on the homogeneous combination of H_2 and O_2 between 352° and 421° was investigated by a static method, porcelain reaction vessels being used. Between 372° and 421° , with pressures of H_2 and O_2 , resp., 440 mm. and 200 mm., no reaction occurs if the partial pressure of NO_2 is less than 0.17 mm. or greater than a value varying from 0.83 at 370° to 3.3 or more at 421° . Within this range of partial pressure of NO_2 the mixt. explodes. The curves for max. and min. partial pressure of NO_2 appear to intersect at about 350° and partial pressure of about 0.5 mm. of NO_2 . The action of the NO_2 is believed analogous to that of a "detonator" in that some reaction between NO_2 and one of the reacting gases is either sufficient or insufficient to initiate the explosion of H_2 and O_2 .

The exact nature of this reaction of NO_2 is not known. Possible analogy may exist between this detonator effect and the effect of traces of water vapor on such actions as the formation of NH_4Cl from NH_3 and HCl .

P. H. EMMETT

Compounds between catalysts and substrates and their reactivity. H. V. EULER. *Trans. Faraday Soc.* 24, 651-62(1928); cf. *C. A.* 20, 3739; 22, 717.—A theory of the hydrolysis of esters postulating the formation of compds. between catalysts and substrates is presented. The expression for the rate of reaction contains 2 consts., K , the dissocn. const. of the substrate and rq the reaction velocity const. of the substrate ion. The theory, in contrast to the "shock theory" of catalysis in solns., introduces chem. criteria for the possibility of salt formation between catalytic acid and substrate. No case has been found in which the supposition of salt formation between substrate and acid or basic catalyst contradicts chem. experience. The possibility of enzyme action occurring through the formation of an enzyme-substrate complex is pointed out and calcs. are made for the value of rq of the substrate enzyme complex.

P. H. EMMETT

Negative catalysis in slow and induced reactions. N. R. DHAR. *Trans. Faraday Soc.* 24, 567-70(1928); cf. *C. A.* 19, 2590; 22, 3539.—The application of the principles of neg. catalysis to the preservation of oils, turpentine, Na sulfite, etc., and to the prevention of *photooxidation of rubber, wood, paper, etc.*, have been successfully tried. Explanations of induced thermal oxidations and photochem. reactions on a basis of activation by ions formed in the exothermic reactions are discussed. Christiansen's concept of chain reactions to explain neg. catalysis is deemed unnecessary.

P. H. EMMETT

The catalytic activity of hydrogen ions in ethyl alcohol. HEINRICH GOLDSCHMIDT. *Trans. Faraday Soc.* 24, 662-6(1928); cf. *C. A.* 22, 1891.—A study of the rate at which esters are formed in EtOH by acetic, phenylacetic, normal butyric and isovaleric acids, using as catalysts picric acid, trinitro-*m*-cresol, trichloroacetic acid and trichlorobutyric acid led to the conclusion that "the H-ion concn. is not the only decisive factor in the catalytic effect of acids in EtOH."

P. H. EMMETT

Phosphorescence and autocatalysis during slow combustion. F. GILL, E. W. J. MARPLES AND H. C. TERR. *Trans. Faraday Soc.* 24, 574-87(1928).—The temp. at which phosphorescence and chem. change appear during the slow combustion of mixts. of air with CS_2 , Et_2O , AcH , amylene, or hexane was studied exptly. CS_2 was unique in that the rate of combustion decreased when the partial pressure of CS_2 in the mixt. increased. Autoxidation of C_6H_6 , CH_4 , EtOH , etc., took place when these vapors were added to the mixt. of air and CS_2 or of air and ether. PbEt_4 , iron carbonyl, I, C_2H_4 and numerous other materials acted as inhibitors in each of the above gas mixts. The results suggest that peroxidation, occurring at the interface of nuclear particles, is directly responsible for phosphorescence, for autocatalysis and for *detonation* in the internal-combustion engine. Inhibitors, by reacting with the peroxides primarily formed, remove their active O and energy and thus destroy the positive catalyst of combustion and the cause of phosphorescence and detonation. The marked action of PbEt_4 and of iron carbonyl in contrast to AcH in inhibiting the combustion of hexane leads to the conclusion that the phosphorescence in the case of the hexane is due to formation of peroxides of hexane and not to the intermediate formation of aldehydes. The insertion of metal foils in the glow seemed to conc. the latter on the surface of the metal and at the same time increase the temp. to which the mixt. had to be heated to enable it to undergo self-ignition. This inhibitory action of metals is in accord with the view that organo-metallic compds., such as PbEt_4 , owe their efficacy to the colloidal metal formed by thermal decompn. at the surface of nuclear particles.

P. H. EMMETT

Catalytic phenomena in the tautomerism of certain α -diketones. HENRI MOUREU. *Trans. Faraday Soc.* 24, 562-4(1928); cf. *C. A.* 22, 1341, 3155.—The activity of alk. catalysts including KOH, diethylamine, piperidine, pyridine, quinoline, etc., toward the tautomeric transformation from A to B form of methylbenzylglyoxal and of phenylbenzylglyoxal was detd. Glass was found to be a sufficiently good catalyst to transform 40% of the Me compd. from A to B form in less than an hour, while the phenyl compd. changes completely to equil. by mere distn. *in vacuo*. Quartz manifested no catalytic activity toward the transformation. Detns. of the equil. in the liquid phase at 100° showed 64% of the enolic form A, and 36% of the ketonic form B for the Me compd., while at 70° the values were 71 and 29%, resp. The catalytic transformation probably involves the formation of an intermediate compd.

P. H. EMMETT

Interaction between nitrogen trichloride and nitric oxide—reactions of compounds with odd electrons. WILLIAM A. NOYES. Univ. of Illinois. *J. Am. Chem. Soc.* 50,

2902-10(1928).—At 0°, the action of NO on NCl₃ in CHCl₃ + CCl₄ is chiefly that of catalytic decompn. of NCl₃; at -20°, about 1/4 of NCl₃ is converted into N₂O + Cl₂; at -80°, the reaction is chiefly NCl₃ + 2NO = N₂O + NOCl + Cl₂. Attempts to isolate NCl₃, which is considered an intermediate product, were unsuccessful. In petroleum ether at -130° to -140°, the reaction is NCl₃ + NO = N₂O + 1/2 Cl₂. The HCl formed by the action of NCl₃ on petroleum ether catalyzes the reaction NOCl + NCl₃ = N₂O + 2Cl₂. The structure of N₂O is probably $\ddot{O}:\overset{+}{N}::\overset{-}{N}:$, the bond between O and N being semipolar.

DAVID DAVIDSON

Kinetics of nitrous acid. V. Kinetics of the nitrous acid-nitric acid-nitric oxide reaction. E. ABEL, H. SCHMID AND S. BABAD. Techn. Hochschule Wien. *Z. physik. Chem.* 136, 419-29(1928); cf. *C. A.* 22, 4329.—The complete velocity equation for the decompn. or the formation of HNO₂: $\pm d(\text{HNO}_2)/dt = \pm k_1(\text{HNO}_2)^4/p^2_{\text{NO}} \mp k_2(\text{HNO}_2)(\text{H}^+)(\text{NO}_3^-)$, was verified. The HNO₂, in the directions of its decompn. and formation has a neg. or pos. role, and otherwise is a negative autocatalyst. The latter action is in spite of the high potential with which HNO₂ acts as an anticatalyst. The values of k_1 and k_2 obtained in the formation and decompn. reactions are in satisfactory agreement. VI. Equilibrium of the nitrous acid-nitric acid-nitric oxide reaction together with its kinetics. E. ABEL AND H. SCHMID. *Ibid* 430-6.—The equil. const. K_e for the HNO₂-HNO₃-NO reaction, as detd. from the forward and reverse reactions, is defined by the relation: $(\text{H}^+)(\text{NO}_3^-)p^2_{\text{NO}}/(\text{HNO}_2)^3$. The thermodynamic equil. const. $K = (a_{\text{H}} \cdot a_{\text{NO}_3} \cdot p^2_{\text{NO}})/a^3_{\text{HNO}_2} = 29$ at 25°C. was obtained, in which a represents the activity of the ion in question. From this equation, the activity coeff. of HNO₂ was calcd. With the activity coeffs. the equil. equation becomes: $\pm d(\text{HNO}_2)/dt = (\pm k'_1 a^3_{\text{HNO}_2}/p^2_{\text{NO}} \mp k'_2 a_{\text{H}} a_{\text{NO}_3})(\text{HNO}_2)$, where $k'_1 = 46$ and $k'_2 = 1.6$ at 25° and the concns. are in moles/l., the pressure in atms., and the time in mins.

J. H. PERRY

Reaction between nitric oxide and hydrogen sulfide. J. A. PIERCE. Johns Hopkins Univ. *J. Phys. Chem.* 33, 22-36(1929).—The reaction between NO and H₂S was studied in a glass chamber at temps. between 28° and 100°. The velocity of reaction was slowest when no catalyst was used. Silica gel or glass wool accelerated the reaction about equally. The mechanism of the reaction is as follows: 2 mols. of NO associate to form N₂O₂. When H₂S impinges upon N₂O₂ adsorbed by the catalyst or by the walls of the contg. vessel, S, N₂ and H₂O are formed. The H₂S is adsorbed by the colloidal S and oriented so that its H ion extends outward from the surface. Accumulation of colloidal S inhibits the reaction, apparently by coating the catalyst. P. believes that the glass in the reaction chamber was acted upon by H₂O and H₂S to form amorphous SiO₂, which acted as a catalyst even in the absence of added SiO₂ gel or glass wool.

LOUISE KELLEY

The conversion of thiosulfuric acid to polythionic acids with the help of catalysts. A. KURTENACKER AND A. CZERNOTZKY. Techn. Hochschule, Brünn. *Z. anorg. allgem. Chem.* 175, 367-82(1928).—Detailed expts. are made on the effects of arsenite, arsenate, SbCl₃, SnCl₄ and Mo^{VI}, W^{VI}, Hg^{II}, Pb and Bi on the conversion of thiosulfate to polythionate. Only salts of those metals which belong to the group of thio acids, and which form thio or thiooxy salts assist in the decompn. of thiosulfates in the direction of polythionate formation. The results of Bassett and Durrant (cf. *C. A.* 21, 3844) are confirmed.

G. L. CLARK

Inhibition in chemical reactions. ERIC K. RIDEAL. *Trans. Faraday Soc.* 24, 571-4(1928).—The mechanism of inhibitor action in the 2 types of chain reactions, namely the "atom chain" of Nernst, and the "activated product chain" of Christiansen, is discussed. The inhibitors function on the first type of chain by acting as atom acceptors, and on the second by deactivation of the active products formed in a given reaction. Ions may function in chain reactions either by initiating chains through the energy evolved on recombination, or by forming clusters capable of undergoing reaction. The latter possibility is well illustrated by the fact that at. H reducing CuO does not induce reduction by mol. H₂, whereas if H⁺ is present, 3 hydrogens react, presumably an H₃⁺ cluster.

P. H. EMMETT

The inhibitive action of alcohols on the oxidation of sodium sulfite. HUBERT N. ALYEA AND HANS L. J. BÄCKSTRÖM. Princeton Univ. *J. Am. Chem. Soc.* 51, 90-109(1929); cf. *C. A.* 21, 2835; 22, 717.—The oxidation of Na₂SO₃ was studied in the presence of isopropyl, secondary butyl, and benzyl alcs. at 21 ± 0.5°. The chain length of the sulfite oxidation was the same for the thermal and photochem. reactions; the breaking of a chain induced the oxidation of two alc. mols. With increasing concn. of alc. the rate of oxidation of alc. increased until a concn. was reached

bove which the rate was const. In mixts. of alcs., each one was oxidized in proportion to its concn. and relative inhibitory power. This did not hold for hydroquinone-*lc.* mixts. where most of the chains were broken by the hydroquinone. The presence of Cu accelerates the thermal reaction without altering the ratio of sulfite oxidized to alc. oxidized. *Isopropyl and secondary butyl alcs.* were purified by refluxing several liters with 2 g. of *p*-nitrophenylhydrazine and fractionating in an atm. of N₂. Methods for the colorimetric detn. of acetone, ethyl methyl ketone and benzaldehyde are described.

ARTHUR FLEISCHER

Definition of "area" in contact catalysis. F. P. BOWDEN. *Nature* 122, 647-8 (1928).—The methods for detg. the surfaces of contact catalysts are (1) the electrolytic method, and (2) the surface oxide method. The former (cf. *C. A.* 22, 4045) gives the area accessible to H ions in soln. and may be termed the "accessible" area. The second method is that developed by Constable (cf. *C. A.* 22, 4335) and is the area of metal catalysts deduced by observing the formation of surface oxide films many mols. in thickness. The area found by method (2) for an activated Ni catalyst is 1.3 to 4.5 times the apparent area. By method (1) the accessible area of rolled metal may be from 2 to 5 times its apparent area, for sand-papered metal 10 times, and for Ni after activation by alternating oxidation and reduction—46 times its apparent area.

P. H. EMMETT

Theory of wall reactions. M. PÓLÁNYI. *Chem. Rund. Mitteleuropa Balkan* 4, 160 (1927).—For the sp. case of the catalytic acceleration of the formation of diatomic from monatomic H at glass walls Frenkel's relation $q = 15T$ g.-cal., where q is the adsorption potential, is applied. The av. value of q for moist glass is 1500-4000 g.-cal., for dry glass and quartz > 4500 g.-cal., and for metal 40,000 g.-cal.

B. C. A.

The catalytic activity of metallized silica gels. V. The oxidation of ethylene. I. H. REYERSON AND L. E. SWEARINGEN. *J. Am. Chem. Soc.* 50, 2872-8 (1928); cf. *C. A.* 22, 1520.—Mixts. of C₂H₄, O₂ and N₂ were passed at temps. from about 100° to 500° and varying rates of flow over SiO₂ gel metallized with Ag, Au, Pt or Pd. The products of oxidation were CO₂ and water. In no case did the tests show the presence of intermediate products of oxidation. The catalysts were effective at lower temps. than previously reported, Cu, Pt and Pd beginning to be effective at about 100°. Ag appeared to be less effective. It is suggested that collisions of C₂H₄ mols. with O₂ mols. which are adsorbed and activated by the effective catalyst centers, result in a reaction, whereas collisions of O₂ mols. with adsorbed C₂H₄ mols. are ineffective.

DON BROUSE

Ceria-thoria catalysts. A. B. GOGGS. *J. Chem. Soc.* 1928, 2667-9.—The influence of mixed Ce₂O₃-ThO₂ catalysts on the combustion of CO was studied. The rate of formation of CO₂ attains a max. with mixts. contg. 0.96% Ce₂O₃. The catalyst found by Swan most effective for the oxidation of H₂ is therefore the most efficient for the oxidation of CO also.

ALBERT L. HENNE

Catalytic decomposition of sodium hypochlorite solutions. II. Iron oxide as promoter in the copper oxide catalysis of sodium hypochlorite. JOHN R. LEWIS. Univ. of Wisconsin. *J. Phys. Chem.* 32, 1808-19 (1928); cf. *C. A.* 22, 1522.—The mixed oxides were obtained by adding NaClO soln. to a known amt. of a mixt. of FeCl₃ and CuCl₂, the fixed alkali present in the former reacting to give the hydrated oxides of Fe and Cu. The results show that the most effective mixt. of catalyst and promoter is about 1 mg. atom of Cu to 1 mg. atom of Fe. The temp. coeff. is low for the unpromoted reaction, but normal for the promoted reaction. The function of the promoter, acting as a support for the catalyst, is to stabilize the catalyst by preventing the destruction of the active centers. The rate of reaction is proportional to the concn. of catalyst present.

E. G. VAN DEN BOSCHE

The synthesis of water with a silver catalyst. II. Energy of activation and mechanism. ARTHUR F. BENTON AND JOSEPH C. ELGIN. Univ. of Va. *J. Am. Chem. Soc.* 51, 7-18 (1929); cf. *C. A.* 21, 691.—An earlier study of the rate of combination of H₂ and O₂ in contact with a Ag catalyst was in part repeated at 110° and 100°. Measurements of the adsorption of H₂, O₂ and H₂O by the catalyst were made at 110° and 100°. H₂ was not measurably adsorbed. O₂ was strongly adsorbed, the amt. being nearly independent of temp. and pressure. The effective surface area of the catalyst was calcd. from the O₂ adsorption, on the assumption that the latter represents a monatomic layer. Kinetic adsorption expts. on H₂O vapor showed some adsorption of H₂O from a current of H₂, but much more from a current of O₂. A Langmuir adsorption isotherm fits the results for adsorption of H₂O. From this equation the fraction of the surface free from adsorbed H₂O during catalysis was calcd. The rate of the reaction 2H₂ + O₂ → 2H₂O was found by measurement to be independent

of the O_2 pressure, but proportional to the H_2 pressure and to the fraction of the surface free from adsorbed water. The energy of activation calcd. from the temp. coeff. was 16,000 cal. \pm 1000. The rate of reaction measured agrees with that calcd. on the hypothesis that the reaction results from every collision of gaseous H_2 with "dry" adsorbed O_2 in which the total energy available on collision exceeds 16,400 cal.

R. L. DODGE

Studies of copper catalysts prepared from precipitated hydroxides. I. Activity as a function of the temperature of precipitation. PER K. FROLICH, M. R. FENSKE AND D. QUIGGLE. Mass. Inst. Tech. *J. Am. Chem. Soc.* 51, 61-5(1929); cf. *C. A.* 22, 3338.—The activity for the decompn. of CH_3OH of Cu catalysts prepd. from the NH_3 pptd. hydrates varied markedly with the temp. of pptn. A max. in activity was observed with catalysts pptd. at about 22°. X-ray examn. of the dried gels before reduction indicated that the activity was assocd. with small particle size. The max. of the activity curve may have been the result of 2 opposing factors, (1) the tendency for the initial particle size to decrease with decreasing temp. of pptn.; and (2) the tendency for the initially formed particles to grow while drying at 110°. II. Comparison of sodium hydroxide and ammonia as a precipitating agent. PER K. FROLICH, M. R. FENSKE, L. R. PERRY AND N. L. HURD. Mass. Inst. Tech. *Ibid* 187-93(1929). Cu catalysts prepd. by pptn. with NaOH are more active in the decompn. of CH_3OH than those pptd. with NH_3 . The difference is due to promoter action of the occluded Na salts. The NaOH-pptd. catalysts, like other promoted Cu catalysts, favor $HCOOCH_3$, rather than $HCOOH$ production from CH_3OH .

R. L. DODGE

Catalysts for the formation of alcohols from carbon monoxide and hydrogen. III. X-ray examination of methanol catalysts composed of copper and zinc. PER K. FROLICH, R. L. DAVIDSON AND M. R. FENSKE. Mass. Inst. Tech. *Ind. Eng. Chem.* 21, 109-11(1929); cf. *C. A.* 22, 3338; 23, 816.—Catalysts composed of Cu and Zn in various proportions, made by co-pptn. of the hydrates, dehydration of the gel and reduction with CH_3OH vapor at 200-220°, were examd. by x-rays. The details of the expts. will be reported elsewhere by Aborn. The results show that at every compn. the catalyst is decidedly cryst., possessing the characteristic crystal structure of the 2 components, Cu and ZnO. However, the unit-cell sizes of each are markedly influenced by the presence of the other. Correlation of these dimensions with measurements of the decompn. of CH_3OH points to a definite relation between the sp. catalytic effect (as indicated by the character of the product) and the distance between the atoms of the 2 components. ZnO, ordinarily considered a non-reducible compd., undoubtedly is partly reduced in the presence of CuO.

R. L. DODGE

The graphical representation of a four-component system. H. v. PHILLIPS-BORN Tonind. *Zig.* 53, 45-8(1929).—A projection of the usual tetrahedron on a square or on 2 adjacent equilateral triangles will allow any 4-component cement to be represented by a line joining 2 points. Examples are given.

F. O. A

The determination of vapor and liquid compositions in binary systems. I. Methanol-water. J. B. FERGUSON AND W. S. FUNNELL. *J. Phys. Chem.* 33, 1-8(1929). By means of a new type of app. which consisted entirely of glass the total and partial pressures of the system CH_3OH-H_2O were measured at 39.90°. The data were obtained from 3 sets of observations, viz., the wt. of the liquid of known compn. first introduced, the pressure of the system at equil., and the wt. of a known vol. of the vapor. The results, together with those of former investigators, were critically examined by means of Miller's abacus (cf. *C. A.* 19, 3413).

H. F. JOHNSTONE

The diagram of state of the system silver nitrate-cesium nitrate. A. P. PALKIN. *J. Russ. Phys.-Chem. Soc.* 60, 317-20(1928).—M. ps. were detd. from cooling curves, other transition points from heating curves. Temp. was measured with a registering pyrometer. $AgNO_3$ m. 208°; a polymorphic transformation occurs at 159° (for $CsNO_3$ at 151°). There are eutectics at 168.5° (82.5% $AgNO_3$) and 163° (67.5% $AgNO_3$). The liquidus curve exhibits a max. at 75% $AgNO_3$ and 171.5°; at 173° and 52.5% $AgNO_3$ there is a sharp break, beyond which the curve rises smoothly towards the m. p. of $CsNO_3$. There is thus evidence for the existence of the compds. $AgNO_3.CsNO_3$ (vitreous mass crystg. 172-2.5°) and $3AgNO_3.CsNO_3$ (elongated prisms). The system $AgNO_3-3AgNO_3.CsNO_3$ is a binary alloy with a eutectic at 168.5°. Polymorphic transformation was traced up to 80% $AgNO_3$. No solid solns. exist. The system $3AgNO_3.CsNO_3-CsNO_3$ contains the compd. $AgNO_3.CsNO_3$ decompg. above 173°. Solid solns. are again absent. The formula $Ag_3[Cs(NO_3)_4]$ is proposed for the double salt.

B. SOYENKOFF

The equilibrium diagram for the system sodium thiosulfate + sodium chloride + water at 255°. V. P. RADISHCHEV. *J. Russ. Phys.-Chem. Soc.* 60, 821-4(1928).—The

satd. solns. were dried at 105° , weighed and titrated for $\text{Na}_2\text{S}_2\text{O}_4$. The soly. of NaCl at $25^\circ \pm 0.1^\circ$ in H_2O was 26.45% by wt., that of $\text{Na}_2\text{S}_2\text{O}_4$ 43.10%. At the mutual satn. point, 9.86% NaCl and 32.98% $\text{Na}_2\text{S}_2\text{O}_4$ were found. The soly. isotherm consists of 2 rectilinear branches meeting at the above point. Conclusion: $\text{Na}_2\text{S}_2\text{O}_4 \cdot 5\text{H}_2\text{O}$ is not dehydrated by the addn. of NaCl at 25° . B. SOYENKOFF

A phase-rule investigation of cupric bromide in aqueous and hydrobromic acid solutions. SYDNEY R. CARTER AND NORMAN J. L. MEGSON. Univ. of Birmingham. *J. Chem. Soc.* 1928, 2954-67.—The soly. curve of the system $\text{CuBr}_2\text{-H}_2\text{O}$ over the range 0° to 50° indicates the presence of one or the other of the 2 solid phases, $\text{CuBr}_2 \cdot 4\text{H}_2\text{O}$ and CuBr_2 . Below $18.0 \pm 0.05^\circ$, $\text{CuBr}_2 \cdot 4\text{H}_2\text{O}$ is stable; above that temp. CuBr_2 is stable. The soly. of CuBr_2 is about 1030 g. per l. and there is but little variation from 0° to 50° . The density, d_{40}^{25} , for the satd. soln. = 1.84. The soly. of $\text{CuBr}_2 \cdot 4\text{H}_2\text{O}$ is less than that of CuBr_2 , below 18° , and decreases to about 1000 g. per l. at 0° . The soly. curves for the system $\text{CuBr}_2\text{-HBr-H}_2\text{O}$ at 25° indicate only 1 solid phase, CuBr_2 , but it has 2 forms the α , rhomboidal crystals and the β non-cryst. The break between the 2 forms occurs at 26% HBr . A metastable portion of the system has as its solid phase at 25° , a compd. whose probable formula is $3\text{CuBr}_2 \cdot 2\text{HBr} \cdot 6\text{H}_2\text{O}$. At 0° the soly. curve for the system $\text{CuBr}_2\text{-HBr-H}_2\text{O}$ shows a break corresponding to the 2 stable phases $\text{CuBr}_2 \cdot 4\text{H}_2\text{O}$ and $\beta\text{-CuBr}_2$. No indications of the compd. $\text{CuBr}_2 \cdot 2\text{H}_2\text{O}$ were found. At high acid concns. the solns. are violet and $\beta\text{-CuBr}_2$ is present at both 25° and at 0° . As the concn. of HBr decreases the color changes to brown and $\alpha\text{-CuBr}_2$ is present at 25° and $\text{CuBr}_2 \cdot 4\text{H}_2\text{O}$ is present at 0° . F. E. BROWN

System: beryllium oxide silicon dioxide. F. MACHATSCHKEI. *Z. physik. Chem.* 133, 253-62(1928).—Comparison of the Debye-Scherrer diagrams given by mixts. of BeO and SiO_2 in proportions corresponding with the ortho- and metasilicates indicates the existence, at temps. between 1000° and the m. p., of the orthosilicate phenacite. Both molten phenacite and molten mixts. of the 2 oxides yield when cooled rapidly cryst. BeO and a glass contg. BeO ; Be metasilicate cannot be obtained by this method and is probably not stable in the cryst. condition. B. C. A.

Equilibrium in the systems: zinc sulfate-sodium sulfate-water at 0° and 25° ; manganese sulfate-sodium sulfate-water at 0° , 25° , and 35° and cobalt sulfate-potassium sulfate water at 25° . ROBERT M. CAVEN AND WM. JOHNSTON. Royal Tech. Coll., Glasgow. *J. Chem. Soc.* 1928, 2506-14; cf. *C. A.* 18, 3329; 21, 523.—At 25° $\text{ZnSO}_4\text{-Na}_2\text{SO}_4 \cdot 4\text{H}_2\text{O}$ forms, but at 0° it does not. The soly. of Na_2SO_4 is increased by ZnSO_4 , while the soly. of ZnSO_4 is decreased by Na_2SO_4 . At 25° and 35° $\text{MnSO}_4\text{-Na}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$ forms but not at 0° . The soly. of MnSO_4 is decreased by Na_2SO_4 . At 0° the solid phase is the heptahydrate, at 25° the tetrahydrate, and at 35° the monohydrate. At 0° and 25° the soly. of Na_2SO_4 is increased while at 35° it is decreased, the solid phase being anhyd. Na_2SO_4 . At 25° $\text{CoSO}_4\text{-K}_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$ forms. The soly. of each salt is increased by the other. ARTHUR FLEISCHER

Decomposition pressure of nitrides. RICHARD LORENZ AND JAMES WOOLCOCK. Univ. of Frankfurt. *Z. anorg. allgem. Chem.* 176, 289-304(1928).—A short-circuit vacuum furnace is used for this work, a device for maintaining const. voltage being described. The action of N_2 upon Ti , Ta , Mo , Zr , U and B is studied, neg. results being obtained with Ti , Ta , Mo and Zr . The decompn. pressure of boron nitride is measured between 1695° and 2045° , and ranges from 23 mm. at 1695° to 158 mm. at 2045° . The reaction is reversible, but its velocity in the vicinity of equil. is very small. $\log p$ plotted against $1/T$ gives an approx. straight line. The heat of formation per mol of BN is calcd. as 28,100 cal. In the system U-N it is shown that N_2 pressure in equil. with substances contg. U and N increases with increasing N content. The equil. is studied at 1280° and 1480° , p ranging from 2.5 mm. to 676 mm. at 1280° as absorbed N increases from 0.0992 to 0.9230 g. atoms/g. atom U . At the higher isotherm, a smaller N content is obtained at a given p than at 1280° . The compds. U_3N_4 and U_5N_7 are obtained only if the furnace is quickly cooled from higher temps. Products with lower N content are regarded as solns. of nitride in the metal. H. STOERTZ

Melting-point curves of refractory oxides. H. v. WARTENBERG, H. LINDE AND R. JUNG. Tech. Hochschule, Danzig. *Z. anorg. allgem. Chem.* 176, 349-62(1928).—The furnace used in this work and its method of operation are described in detail. The heating chamber is composed of ZrO_2 in the form of a tube, and the heat source is an oil- O_2 burner with a H_2O -cooled tip. Temps. up to 2600° can be attained. The material to be examd. is formed into a hook by means of a suitable binding material, and this is attached to a ZrO_2 rod, the softening point and m. p. being detd. by observing the temp. at which the hook bends or drops form. A control run on a known system

(CaO-Al₂O₃) indicated reasonable accuracy. Study of the system: ZrO₂-Al₂O₃ shows that softening and m. p. can be detd. in mixts. contg. up to 20% ZrO₂; from 20 to 60% ZrO₂ only m. p. can be detd., due to the eutectic (m. 1920°); with 80% ZrO₂ only softening occurs. No indication is given of the formation of an ortho- or metazirconate (Al₂Zr₂O₇ with 35.5% Al₂O₃ or Al₂Zr₂O₇ with 21.6% Al₂O₃). In studying the system CaO-ZrO₂, bakelite lacquer is used as a binder in prepg. the sample. Although CaO melts at 2580° and boils at 2850°, loss of CaO due to vaporization begins to occur at about 2350°. A eutectic is shown at about 40% ZrO₂ and 2230°, with a second eutectic indicated in the vicinity of 75% ZrO₂ (m. 2380°). The meta-compd. CaO·ZrO₂, contg. 69% ZrO₂, probably exists, but doubt is thrown upon the ortho-compd. 2CaO·ZrO₂.

H. STOERTZ

Influence of certain corrections on the results of measurements of the heat of combustion of organic substances. W. SWIENTOSLAWSKI AND H. STARCZEWSKA. *Bull. intern. acad. Polonaise* 1928, No. 3A, 85-97; *Roczniki Chem.* 8, 195-209(1928).—In a study of a series of org. substances the general equations are given and the corrections for reduction to isothermal heat of combustion are calcd. as coeffs. of variation of heat of combustion with temp. The value of 6324 cal._{15°} per g. of C₆H₅COOH is taken as the standard for the heat of combustion. If the combustions are made between 15° and 20° the correction for the coeff. *du/dt* can be neglected. The unknown and the standard should be at the same temp.

L. D. ROBERTS

Calometric researches. II. The heat of combustion of a proposed secondary calorimetric standard, salicylic acid. L. J. P. KEFFLER. Univ. of Liverpool. *J. Phys. Chem.* 33, 37-51(1929).—The heat of combustion of salicylic acid was found to be 5234.8 cal._{15°}/g. weighed *in vacuo*, as a mean obtained from 19 adiabatic combustions of 8 different samples. This value supposedly holds for an isothermal reaction at a temp. of about 20°. A comparison of the degrees of reliability of the data of several investigators is made, and, as a conclusion, the value of 5235 ± 1 cal._{15°}/g. weighed *in vacuo* is suggested for the heat of combustion of the acid. This is to be used as a secondary standard, benzoic acid being the primary. A short survey of the more important errors entailed in bomb calorimetry is also presented.

H. F. JOHNSTONE

The heat capacities at low temperatures of the oxides of tin and lead. RUSSELL W. MILLAR. *J. Am. Chem. Soc.* 51, 207-14(1929).—The heat capacities of SnO and SnO₂, PbO, and H₂PbO₄ have been detd. from 70° to 300°K. A table of their entropies, free energy change and heat of formation at 25° is given.

RAYMOND H. LAMBERT

The heat capacity of methanol from 16°K. to 298°K. and the corresponding entropy and free energy. KENNETH K. KELLEY. Univ. of Calif. *J. Am. Chem. Soc.* 51, 180-7(1928).—The method and app. used are described briefly. Two cryst. forms of the NH₄Cl type were observed. The heat of transition was found to be about 154 cal./mol. and the entropy detd. at 157.4°K. is 30.3 ± 0.2 E. U.

R. H. I.

The heat capacities at low temperatures of "ferrous oxide," magnetite and cuprous and cupric oxides. RUSSELL W. MILLAR. *J. Am. Chem. Soc.* 51, 215-22(1929).—The heat capacities are tabulated and the entropies at 25° calcd.

CLARK. Univ. of Illinois. *Chem. Reviews* 5, 361-4(1928).—A description of the status of theories of at. structure and valence resulting in the joint symposium of chemists and physicists at the 1928 St. Louis meeting of the Am. Chem. Soc. and an introduction to the papers there presented and now published as a monograph. G. L. CLARK

The nucleus of the atom. J. A. CROWTHER. Univ. Reading, England. *Smithsonian Inst. Pub.* 2932, Rept. for 1927, 209-16.—A review. MARIE FARNSWORTH

The atom. W. F. G. SWANN. *Proc. Am. Phil. Soc.* 67, 235-66(1928); cf. *C. A.* 22, 4352.—A review of the story of modern at. structure, and especially of the spectroscopic aspect of the problem of the atom. The theories of Bohr, Sommerfeld, Schrödinger, Born, Heisenberg and others are discussed. FRANK V. JOHNSON, JR.

Statistical deduction of the properties of the elements. E. FERMI. *Atti accad. Lincei* [vi], 7, 342-6(1928); cf. *C. A.* 22, 1902.—From a statistical analysis of the electrons surrounding the nucleus considered as a completely degenerated gas, the general characteristics and some of the anomalies of the periodic classification of the elements can be predicted. B. C. A.

The synthesis of atoms, the whole-number rule and the periodic system of atomic species. WM. D. HARKINS. Univ. of Chicago. *Chem. Reviews* 5, 371-435(1928).—This is a review of H.'s work on: (1) the disintegrative synthesis of atoms (*C. A.* 17, 3449; 21, 855), (2) the evidence for the whole-no. rule (*C. A.* 9, 2335), (3) the building of atoms from H and He (*C. A.* 14, 3573), and (4) the periodicity of properties originating in the nucleus (*C. A.* 14, 1628). The last is revealed by the high stability and abundance of atoms of even at. no., or electronic no., and of those of which the at. wt., or isotopic no., is divisible by 4 and which possess a secondary periodicity of 2.

H. F. JOHNSTONE

Molecular hydrogen in sunspots. GIORGIO PICCARDI. *Nature* 122, 880(1928).—A photograph of the spectrum of sunspots taken in the second order with dispersion 1 A. U. = 1 mm., and comprising the red portion of the spectrum between $\lambda 5900$ and $\lambda 6200$, contained unidentified lines which were relatively intense in the spots and very faint or entirely absent in the photosphere. Since mol. H_2 can exist under conditions prevailing in the spots ($4000^\circ K.$ and 10^{-2} or 10^{-1} atm.), P. compared these lines with recent accurate measurements of the secondary spectrum of H_2 (cf. Gale, *C. A.* 22, 757) and a large-scale map (0.25 A. U. = 1 mm.) of the sunspot spectrum taken at Mt. Wilson. The comparison between $\lambda 6400$ and $\lambda 4450$ showed numerous coincidences with a max. error of about ± 0.03 A. U. in the I. A. system. All the lines which are presumed to be those of the secondary spectrum of H_2 show no trace of the Zeeman effect as is seen in the map. They behave as do the lines of CaH_2 , MgH_2 , etc., also present in the spots. Hence mol. H_2 can be present in the higher regions of a sunspot beyond the influence of the magnetic field. FLORENCE N. SCHOTT

The energy levels of the elements from chromium to lanthanum in the region of x-rays. F. P. MULDER. Univ. Groningen. *Arch. neerland. sci.* IIIA, 11, 167-205 (1928).—The app. and procedure for obtaining energy levels of solid elements is described. The elements from Cr to La in the periodic system have been studied. The method of placing a quantity of the element on the anticathode to which a photographic plate is then exposed and that in which the absorption takes place on a photographic plate itself were both used to record results. The manner of prep. screens is described. The results are given in tabular form where both new and old data are recorded for wave length for some of the L series. The calcd. energies are also tabulated. The general trend of curves for energy levels is discussed at length.

RAYMOND H. LAMBERT

Sub-atomic energy. A. S. EDDINGTON. *Mem. Proc. Manchester Lit. Phil. Soc.* 72, 101-17(1927-8).—The problem of sub-at. energy is now a very practical and urgent one for the astronomer. The source of stellar energy may originate from various sub-at. processes. Consideration is made of why some form of liberation of sub-at. energy—either annihilation or transmutation of atoms—must be postulated for the sun and stars. Investigations of Kohlhörster and Millikan on the penetrating radiation from space may indicate sub-at. processes in celestial regions. FRANK V. JOHNSON, JR.

The question of the existence of "mezo" products in the actinium decomposition series. J. v. WESZKLSZKY AND L. IMRE. Univ. Budapest. *Z. anorg. allgem. Chem.* 175, 141-60(1928).—The deviation of the α -ray products of the Ac series from the Geiger-Nuttall relation and the complex α - and β -rays of RdAc need further study. A study of RdAc, quantitatively sep'd. from other Ac decompn. products by sublimation, shows no indication of contamination by "mezo" products of the Ac series. MARIE FARNSWORTH

Decrease of luminosity of self-luminous materials. W. S. ANDREWS. *Gen.*

Elec. Rev. 31, 610-1(1928).—*Mesothorium* gives greater luminosity than an equal wt. of Ra, and the decline is slower.

BENJAMIN MILLER

An attempt to polarize electron waves by reflection. C. J. DAVISSON AND L. H. GERMER. Bell Telephone Labs., New York. *Nature* 122, 809(1928).—A homogeneous beam of electrons is reflected at 45° incidence from a {111} face of a Ni crystal and the reflected beam is then reflected at the same angle of incidence from a 2nd similar crystal, rigidly attached to a Faraday cage placed in the direction of regular reflection. The second crystal and cage can be rotated about the axis of the electron beam, the whole forming a reflection polarizer for electrons. Only electrons which have retained nearly all of the original energy are allowed to enter the cage. Any variation of current as the analyzing crystal was rotated was less than $1/100$ of the total current, which corresponds to the uncertainty of the measurements; to this order of accuracy, there is no polarization of electron waves by reflection. Two new maxima of regular reflection of bombarding potentials of 20 and 55 v. were found in addn. to those of 77, 103 and 120 v. previously reported.

W. WEST

Distribution of electrons in a metal. J. E. LENNARD-JONES AND H. J. WOODS. *Proc. Roy. Soc. (London)* A120, 727-35(1928).—Thomas has applied the new statistics of Fermi-Dirac to the distribution of electrons in heavy atoms. The basic idea is that the "electron gas" surrounding a nucleus is "degenerate," so that every cell of extension h^3 of a six-dimensional phase space contains 2 electrons, spinning in opposite directions to one another. A differential equation is obtained which has been solved by Thomas and Fermi by numerical methods. Another application of the statistics has been made by Sommerfeld to the free electrons of a metal. S.'s work is criticized on the ground that he has neglected the interaction of the electrons and the atomic cores. The object of the present paper is to find the av. distribution of electrons (by the means used by T. and F. for isolated atoms). The same differential equation is obtained as that of T. and F., but the boundary conditions are different. The differential equation inside a cube subject to the simple boundary conditions that $V_r \rightarrow E$ at the center and $\partial V/\partial n = 0$ at the boundary proves to be insol., and the problem has been further simplified to give a kind of two dimensional metals, where the nuclei are replaced by a series of parallel line-charges so arranged as to intersect a plane perpendicular to them in a square array. The following equation is ultimately obtained: $(\partial^2 V/\partial x^2) + (\partial^2 V/\partial y^2) = k^2 V$, where $k^2 = 16\pi^2 m e^2 / \hbar^2$, being the mass of the electron, e the charge and U the potential field. This is solved subject to certain conditions. By this means, the work required to move an electron from any point in the crystal is obtained, and a number of equipotential lines for a crystal are plotted. Near a nucleus, the equipotential lines are nearly circles, which are gradually deformed until a critical curve is reached. This extends throughout the crystal and encloses another system of closed curves. The electrons in these regions may be regarded as "shared," the shared electrons forming a lattice array which interpenetrates that of the nuclei. This provides some justification for the model of a metal proposed by Lindemann and Thomson.

ALBERT L. HENNE

The effect of the image force on the emission and reflection of electrons by metals. L. W. NORDHEIM. *Proc. Roy. Soc. (London)* A121, 626-39(1928); cf. *C. A.* 22, 1903, 3829.—A mathematical presentation of a more accurate calcn. of D , the emission coeff., and R , the reflection coeff., for electrons emitted and reflected by metals

H. W. WALKER

The special distribution of photoelectrons produced by x-rays. H. J. WILLIAMS, J. M. NUTTALL AND H. S. BARLOW. *Proc. Roy. Soc. (London)* A121, 611-25(1928); cf. *C. A.* 22, 1538.—Expts. on the longitudinal distribution of photoelectrons emitted from O_2 and N_2 by absorption of x-rays of wave lengths of 0.54, 0.61 and 0.71 Å U. resp., show that the av. forward momentum of a photoelectron is 40% greater than that of an absorbed quantum. The dispersion of the photoelectrons is satisfactorily represented by the "cos²θ" law of Auger and Perrin. A discussion of theory and previous exptl. results is given. The possible sources of error in the measurements of the photoelectron tracks such as the heterogeneity of the incident radiation, the photography of the photoelectron track, choice of tracks and statistical errors from inaccurate measurement of directions of the photoelectrons are recognized and the precautions taken to eliminate them are described.

H. W. WALKER

The number of "recoil" electrons and the intensity of modified scattering. E. J. WILLIAMS. *Mem. Proc. Manchester Lit. Phil. Soc.* 72, 1-16(1927-8).—The value of the coeff., σ_m , of modified scattering for O and N and radiation of wave length 0.6 Å U., is estd. from exptl. results for the neighboring elements, C and Al. This value agrees to within exptl. error (10%) with the observed mean value of $\tau N_p/N_p$, where

N_r represents the no. of recoil electrons, N_p the no. of photoelectrons, and τ the photoelec. absorption coeff. This result shows that β -rays are produced in these cases which are distinct from the photoelectrons and whose no. is equal to the no. of modified quanta scattered. Comparison of the results is made with the data obtained by Waller and Wentzel. Comparison of the observed ratio of the intensity of modified to unmodified scattering with C, with the theoretical values of the ratio, shows rather serious differences and it seems that the theoretical values as calcd. here are too high. F. V. J., JR.

Some transient effects with ions of low mobility. H. P. WALMSLEY. *Mem. Proc. Manchester Lit. Phil. Soc.* 72, 29-41(1927-8).—In the measurement of ionization curves, the change in field strength, and the time at which the steady state is reached, may be the source of unexpected results. With a variable ionization, the observed currents show a lag with time behind the changes producing them. This is of moment only in dealing with ions of very low mobility. Any change which causes a redistribution of such ions in the elec. field which is employed to measure the currents, produces transient effects which may be comparable in magnitude to the currents measured, and which persist an appreciable time. FRANK V. JOHNSON, JR.

Motion of electrons in gases. J. S. TOWNSEND. *Proc. Roy. Soc. (London)* A120, 511-23(1928).—A reply to the criticisms of Atkinson (cf. C. A. 23, 1049) and others of T's work on ionization of gases by impact. In the investigation method adopted by A, no account has been taken of the motion of agitation of the gas in finding the loss of energy in the simplest case where the mols. or atoms of the gas are supposed to be perfectly elastic spheres. ALBERT L. HENNE

Hysteretic effects in the positive emission from hot bodies. H. P. WALMSLEY. *Mem. Proc. Manchester Lit. Phil. Soc.* 72, 139-56(1927-8).—A review of some of the work on the properties of the pos. ions emitted from hot Pt. It has been suggested that some of the hysteretic effects are due to the presence of ions of comparatively low mobility. The explanations have been extended by taking account of the properties of the particles when charged. They are then found to give a fairly consistent qual. account of the time lag effect when the pressure of the medium is altered, when the temp. is suddenly changed and when changes are made in the elec. fields employed to measure the currents. The effect of particles on the measurements of e/m is discussed. FRANK V. JOHNSON, JR.

Effect of electric fields on the emission of electrons from conductors. A. T. WATERMAN. *Proc. Roy. Soc. (London)* A121, 28-40(1928).—Sommerfeld's modification of the Lorentz electron theory of metals is applied to the problem of thermionic emission in a strong elec. field. This includes a discussion of the vol. distribution of surface charge for a "degenerate electron gas" obeying the Fermi-Dirac statistics. The equations are applied to the extn. of electrons from cold metals and discrepancies between the exptl. and calcd. results are discussed. Conclusion: The extn. of electrons from metals by intense elec. fields involves some factor not considered in any theory as yet proposed. W. W. STIFLER

Photoelectric current as a function of the field in air at ordinary pressures. A. BLANC. *Compt. rend.* 186, 1835-7(1928).—Comparison of the curves obtained for the same metal subjected to different illuminations with those for different metals showed that the form of the curve depends on the nature of the metal. Satn. is attained rapidly in a vacuum, since the no. of electrons emitted does not depend on the field. At sufficiently high pressures, however, the electrons ionize the gas in accordance with Thomson's theory, the mean no. of ions produced by each increasing with the field in a manner depending on the metal. The initial energy and capacity for ionization of the electrons depend on the distance they travel in the direction of the field before meeting a mol. They may even ionize several mols. before uniting with one of them, and satn. is not attained. B. C. A.

Origin of magnetism based on the structure of atoms. KÔTARÔ HONDA. *Sci. Repts. Tohoku Imp. Univ.* 17, 1st. ser., 997-1009(1928); cf. C. A. 22, 2309.—It is shown that while the electrons revolving about the nucleus can produce diamagnetic effects, they cannot give rise to para- or ferromagnetism. By applying the theory of the gyroscope to the H_2 mol. in a magnetic field it is shown that the magnetization due to rotation is exactly offset by that due to precession. Possible effects due to the electrons and protons composing the nucleus are then investigated. Here the electrons revolve with a speed approx. that of light and cannot alone account for ferromagnetism. By assuming that a no. of protons revolve in the opposite direction in a circular orbit outside the electrons, this difficulty is overcome. The effects of thermal agitation in cryst. solids, and changes in magnetic susceptibility due to allotropic transformations are treated on this theory, as well as the formation of a diamagnetic compd. by the union

of 2 paramagnetic atoms and the formation of a ferromagnetic substance from diamagnetic or paramagnetic elements. An explanation is also offered for the fact that the scattering of x-rays from Fe is not affected by a strong magnetic field. W. W. STRIFLER

Magnetic moment of the electron. G. BRATT. *Nature* 122, 649(1928).—Instead of the familiar expression for the magnetic moment of a spinning electron, viz., $eh/4\pi mc$, which leads to the Bohr magneton, a much more complicated equation is deduced from wave mechanics, following particularly the work of Dirac and Darwin. When applied to the very intense fields of the nucleus, this new expression indicates the possibility of magnetic moments considerably less than 1 Bohr magneton. Recent results of Mulliken's on the spectra of isotopes are correlated with this result. W. W. S.

Atomic structure as revealed by crystal reflection of x-rays. G. E. M. JAUNCEY. Washington Univ., St. Louis. *Chem. Reviews* 5, 437-49(1928).—A review of the recent work on the distribution of the electrons in the atoms of rock salt (cf. *C. A.* 22, 2712, 3581). H. F. JOHNSTONE

The influence of the presence of hydrogen on the L_{III} x-ray absorption edge of palladium. J. D. HANAWALT. Univ. of Wisconsin. *Proc. Natl. Acad. Sci.* 14, 953-8(1928).—An x-ray investigation of the distension of the Pd lattice due to absorbed H_2 indicates the existence of Pd_2H . X-ray absorption studies, a Siegbahn vacuum spectrograph being used, showed the occluded H_2 was in chem. combination with the Pd when absorbed (1) during electrolysis and (2) from the gas phase. The relative intensities of the L_{III} absorption edge supports the hypothesis that the complex edge corresponds to the superposition of edge l_1 , due to Pd atoms alone, and edge l_2 , due to Pd atoms combined with H atoms. The latter edge is shifted from the position of the pure Pd edge by 10 X. U., toward shorter wave lengths. It is difficult to say whether the Pd loses or gains an electron in the PdH mol. On this hypothesis the Pd_2H crystal lattice would be a face-centered cubic lattice in which the alternate grating points are PdH mols. and the remaining points Pd atoms. Bibliography 1924-1928. H. W. WALKER

X-ray diffraction of crystal powders and liquids in relation to their constitution. P. KRISHNAMURTI. *Indian J. Physics* 3, 225-40(1928); cf. *C. A.* 22, 2691, 4291, 4292.—X-ray diffraction patterns from liquid ethyl *o*-phthalate, *n*-butyl salicylate, *p*-cymene, salicylaldehyde, methyl salicylate, methyl benzoate, ethyl benzoate, *n*-butyl benzoate, benzyl benzoate, benzyl acetate, oleic acid, *o*-toluidine, geraniol, terpineol, diphenylmethane, and from both liquid and solid *o*-nitroaniline, *o*-nitrophenol, *o*-nitrobenzaldehyde, diphenylamine, *m*-nitrobenzaldehyde, *p*-toluidine, acetophenone oxime, acetamide, show the following characteristics. Liquid *o*- and *m*-disubstituted benzene derivs. give 2 sep. diffraction rings, whereas the *p*-compds. give 1 ring only. For the *o*- and *m*-compds., the outer ring is probably due to the thickness of the mol., the inner ring to its length and breadth. The spacing calcd. for the inner ring alters considerably with change in size and length of substituting groups. For the *p*-compds., just as for long-chain aliphatic compds., only the spacing due to the av. thickness of the mol. is obtained. The inner ring for geraniol was smaller than that due to terpineol, showing that the former consists of longer mols. The most prominent rings of the powder pattern of solids persist in the diffraction pattern of the liquids, undergoing a slight decrease in size, and the rings are broader and more diffuse at the edges for the liquids. Apparently, some of the crystal planes remain intact, though considerably modified, when the substance passes from the cryst. to the liquid state. The spacing corresponding to the outer ring in most of the ortho-compds. is about 3.5 A. U., in fair agreement with Bragg's value of 3.0 A. U. for the thickness of the benzene mol. R. J. HAVIGHURST

The diffraction of x-rays by aqueous solutions of cane sugar, levulose and glucose. P. KRISHNAMURTI. *Indian J. Physics* 3, 209-23(1928).—The x-ray diffraction pattern of a dil. soln. of a sugar, made with $Cu K\alpha$ radiation, shows in addn. to the ring due to water, a general scattering confined to a small region around the central spot, having the appearance of a corona. The intensity of this diffraction disk increases with increased concn. of the soln., until the soln. contains equal quantities of solvent and solute. This disk is attributed to the mols. which are distributed through the solvent at random, much in the same way as gaseous mols. At concns. higher than 1:1, there is diminution of scattering at small angles, and the corona develops into a halo, probably because of the mols. acquiring an approx. uniform spatial arrangement, the scattered waves at small angles destroying each others' effects by interference. The pattern for the most concd. solns. is very much like the pattern for the powder. If the mols. of the 1:1 solns. are distributed at random through the solvent, the angular radius of the disk surrounding the central spot just before it develops into a ring should

give a measure of the av. diam. of the mols. This is found to be 5.86 A. U. for glucose and levulose, and 7.73 A. U. for cane sugar.

R. J. HAVIGHURST

X-ray spectra. Recent investigations in the domain of chemistry. CHARLES PRÉVOST. *Rev. gen. sci.* 39, 663-8(1928).—The hypothesis of induced polarity of an atom or radical is advanced to account qualitatively for recent exptl. results obtained in work on the displacement of wave-length limit for absorption and emission of x-rays and on the fine structure of the absorption edge. Recent work by Krishnamurti, and Stewart and Morrow on x-ray diffraction in liquids is reviewed.

R. J. HAVIGHURST

Direct and indirect characteristic x-rays: their ratio as a function of cathode-ray energy. D. L. WEBSTER. *Proc. Natl. Acad. Sci.* 14, 330-9(1928); cf. *C. A.* 22, 1539, 4363.—The work of a previous paper (*C. A.* 22, 1539) on the ratio of direct rays to total indirect x-rays produced from any ordinary x-ray target is extended. The app. was reconstructed to obtain greater accuracy and the same method was used as in the previous work. The calcn. was carried out in practically the same way as before, except that the assumption that all the primary continuous spectrum x-rays originate in the surface is replaced by the assumption that they originate at a depth equal to the av. depth as measured by the absorption limit method. The value of the ratio of direct rays to total incident rays for Ag is found to be almost const., the data giving 1.83 at 35 kv., and 1.96 at 80 kv. The probable error is high, amounting to 10-20%. The variation of the ratio is not sufficient to vitiate current comparisons of observed line intensities with theories.

B. C. A.

Structure analysis. H. OTT. *Z. Krist.* 66, 136-53(1927).—A general method for the detn. of the positions of atoms in a lattice without the assistance of the structure theory is based on the extinction of x-ray interference.

B. C. A.

Charged spheres, the photoelectric effect, and the fluorescence spectra of x-rays. L. DÉCOMBE. *Compt. rend.* 186, 1291-3(1928).—The production of the characteristic and continuous x-ray spectra is explained on the assumption that all monochromatic x-radiation of given frequency is due to the beats arising from the pulsatory frequencies of 2 cathodic electrons considered as small pulsating spheres, one of which is brought to rest by impact, while the other has a restricted speed less than that of impact. The explanation is also applied to the photoelec. effect of x-rays, to resonance, and to the Compton effect.

B. C. A.

Production and absorption of the K-rays of aluminum. F. HOLWECK. *Compt. rend.* 186, 1203-5(1928).—The absorption coeffs. of rays produced from a water-cooled Al anode with an incandescent cathode in a highly evacuated metallic tube provided with an Al window are 550 and 7400 (approx.) for wave lengths slightly greater and less than the K-discontinuity, resp. This gives a value of about 13 for the ratio J , which is in agreement with that found (14) from the values obtained for the absorption in air at voltages above the critical potential using an Al filter 15μ thick, and from the absorption coeff. of the soft rays of O and N.

B. C. A.

Thermodynamics of the Compton effect with reference to the interior of stars. S. CHANDRASEKHAR. *Indian J. Physics* 3, 241-50(1928).—In a system contg. electrons and quanta under the conditions of a star's interior, the ratio of the probability coeffs. connected with "Compton-type" collisions in which the quantum loses energy and "reversed-Compton-type" collisions in which the quantum gains energy at the expense of the electron is nearly unity. In a system contg. electrons, ionized atoms and quanta, this ratio is nearly 3.3×10^{27} , the reason for this large value being that the reversed Compton effect is due to triple collisions, while the direct effect is due to double collisions between atoms and quanta. It seems probable, therefore, that the softening of high-frequency radiation created in the interior of stars is due to Compton scattering in systems contg. electrons, ionized atoms and quanta; that is, to Compton scattering with bound electrons.

R. J. HAVIGHURST

The Raman effect in the x-ray region. M. PONTE AND Y. ROCARD. *Compt. rend.* 187, 828-9(1928).—The scattering or diffusion of x-rays reported by Davis and Mitchell (*C. A.* 23, 765) is similar in character to the Raman effect in the optical region. Analogies may be observed between the modulation of a wireless carrier wave, explicable by the classical wave theory, the Raman effect, for which the classical theory is not entirely adequate, and the scattering of x-rays for which the wave theory is inadequate and the quantum theory affords the only satisfactory explanation.

A. W. KENNEY

The coloration of kunzite and hiddenite by x-rays. P. L. BAYLEY. *Lehigh Univ. J. Optical Soc. Am.* 17, 350-5(1928); cf. *C. A.* 22, 4067.—Spodumene, a natural Li Al silicate occurs sometimes in large crystals of which one variety called kunzite is pink or purple, and the other variety called hiddenite is yellowish green. A spectro-

photometric study was made to see if the natural green of hiddenite is related to the green color produced in kunzite by x-rays. Polished, nearly perfect crystals were used, and the transmission was studied over a range of wave length from 0.3 to 4.5 μ . The samples were measured in their original condition and after 5 hrs.' exposure to x-rays at a distance of 5 in. from the Mo target of a Coolidge tube operating at 3-5 ma. and 40 kv. There was no marked change in hiddenite after exposure but kunzite turned a distinct bluish green with a transmission similar to that of hiddenite over a considerable range in the optical region and differing most markedly in the infra-red region. The production by x-rays of an absorption band in the infra-red region is so far unique. This behavior of kunzite is completely reproducible. A survey of previous work is given.

A. W. KENNEY

Rotation of molecules induced by light. C. V. RAMAN AND K. S. KRISHNAN. *Nature* 122, 882(1928); cf. *C. A.* 22, 4060.—R. attributes the accompanying continuous spectrum in the scattered spectrum of benzene to a mol. rotation set up when a mol. collides with a light quantum. That the probability of such a mol., rotation should depend, among other factors, on the degree of optical anisotropy of the mol., is supported by the fact that strong optical anisotropic substances as benzene, toluene, and pyridine exhibit the wings of the scattered lines strongly, whereas compds. as CCl_4 , ether, and EtOH , which are more nearly isotropic, optically exhibit the effect feebly. CS_2 , highly anisotropic optically, exhibited strong wings, which appear to consist of unpolarized light.

FLORENCE N. SCHOTT

Rydberg term tables. F. PASCHEN. *J. Optical Soc. Am.* 16, 231-43(1928).—Values of $Z^2N/(m+a)^2$ are tabulated for $Z = 1, 2, 3$ and 4, Z being the no. of the spectrum, N Rydberg's const., m the order no. of the term, and a the Rydberg correction.

B. C. A.

Broadening of Debye lines with cold-worked metals. U. DEHLINGER. *Z. Krist.* 65, 615-31(1927).—With cold-worked Ag, Cu, Ta and α -brass the $K\alpha$ doublet is not resolved, whereas with cold-worked Al and Zn it is sharp. Hence periodic strain and distortion may be a cause of broadening of Debye-Scherrer lines.

B. C. A.

Method of horizontal comparison in the location of spectra of elements. MEGHNAD SAHA AND KANAKENDU MAJUMDAR. *Indian J. Physics* 3, 67-76(1928).—Theoretical

ALBERT L. HENNE

Experimental proof of "negative" dispersion. H. KOPFERMANN AND R. LADENBURG. Kaiser Wilh.-Inst. physik. Chem., Berlin-Dahlem. *Z. physik. Chem.*, Abt. A, 139, 375-85(1928); cf. *C. A.* 23, 25.—"In the pos. column of a Ne discharge at increasing current d. up to about 0.1 amp. per sq. cm. there is found an increase in the anomalous dispersion in the yellow-red s - p lines (p is the state of higher, s that of lower energy content). This indicates a corresponding increase in the excited atoms in the s states. On further increase in current d. a continuous decrease is observed in the amt. of anomalous dispersion of the different s_k - p_k levels ($k = 10, 9, 8, 6, 4, 2$), just as would be expected in consequence of the stronger exciting of the atoms in the p_k states, if the quantum theory dispersion formula concerning "negative" dispersion is true. Control expts. excluded other explanations of the exptl. results, particularly that of a systematically different decrease in the anomalous dispersion of the s_k lines combining at different p_k levels, that is, the lower the p level in question lies, and the stronger it is excited, the greater is the decrease in the corresponding anomalous dispersion."

F. L. BROWNE

Excitation function of spectral lines. W. HANLE. *Naturwissenschaften* 15, 832-3(1927).—The excitation function (excitation probability in relation to the acceleration voltage of the bombarding electrons) of the Hg line 2537 A. U. has been observed in the neighborhood of the excitation potential.

B. C. A.

Temperature of the acetylene-oxygen flame. F. HENNING AND C. TINGWALDT. *Z. Physik* 48, 805-23(1928).—The temp. in different parts of the acetylene-O flame was detd. by Kurlbaum's method of spectral line inversion. Observations were made in the visible region by coloring the flame by means of Li_2CO_3 and in the infra-red region by measurements on the CO_2 band 4.39 μ in the colorless flame, the former giving the temp. in the interior of the flame and the latter that of the outer cone. The hottest point in the normal flame is about 3 mm. above the tip of the luminous cone, where the temp. is about 3100°.

B. C. A.

Dissociation of molecules as disclosed by band spectra. KARL K. DARROW. Bell Telephone Labs., N. Y. *Chem. Reviews* 5, 451-66(1928).—Just as in an atom there may be different ways in which the ionization takes place, with different expenditures of energy, so in a mol., it need not be the normal state of the atoms into which the dissocn. leads. The continuous regions in absorption spectra may be the signs of

dissoen. with transfer of extra energy to the sepd. particles. Such an explanation accounts for the differences between the values for heats of dissoen. as found by thermal methods and as calcd. from the band spectra. The thermal method yields the net amt. of energy expended in transforming the mol. into normal neutral atoms while the spectroscopic method yields the amt. which was spent in effecting the primary dissoen. with no deduction for that restored by the resulting atoms in their succeeding actions. Dissoen. is viewed as taking place when (1) a change in the arrangement of the electrons causes a change in the amplitude of oscillation of the nuclei to the extent that the latter tear themselves apart, or (2) when the mol. spontaneously passes from an excited to a normal state with the emission of enough energy to tear the atoms apart.

H. F. JOHNSTONE

Optical investigations on perylene and its derivatives. I. The visible absorption spectrum of several simple derivatives. ARMIN DADIEU. *Tech. Hochschule, Graz. Z. physik. Chem.* 135, 347-61(1928).—The absorption bands of perylene, $C_{22}H_{14}$, and the 3,9-dichloro, tetrachloro, hexachloro, 3,9-dibromo, 3,9-dicyano, 3,9-diacetyl, 3,9-dicarboxylic acid diethyl ester, 3,9-dibenzoyl and 3,9-*p*-chlorodibenzoyl derivs. in C_6H_6 soln. are detd. with a König-Marten spectrophotometer. The influences of the substituents upon the bands are a displacement towards longer wave lengths, broadening and intensity decrease. A proportionality exists between broadening and the no. of outer-shell electrons of the substituents. The intensity decrease runs parallel; the electron affinities of the substituents and the structure of their electron shells account for the displacement.

G. L. CLARK

Variation of the extinction coefficient with temperature. B. K. MUKERJI, A. K. BHATTACHARJI AND N. R. DHAR. Allahabad Univ., India. *J. Phys. Chem.* 32, 1834-40(1928).—The extinction-coeffs. of the following solns. when measured at varying temps. from 10° to 60° with a Hilger-Nutting spectrophotometer: $N/40 H_2Cr_2O_7$; $N/39.6 I_2$; $N/29.5 K_2C_2O_4$; $N/29.5 I_2$ and $N/10.8 KI$; $N/20 H_2Cr_2O_7$ and $N/28.4 H_2C_2O_4$; $N/10 H_2Cr_2O_7$ and $M/47$ quinine sulfate; $N/3.03$ Rochelle salt, $N/125 Br_2$ and $N/1.65 AcONa$; $KMnO_4$; $AcONa$, $NaNO_2$ and I_2 ; $HCOONa$, I_2 and $AcONa$; $FeSO_4$ and I_2 ; eosin; $(NH_4)_2C_2O_4$ and I_2 ; $CuSO_4$; $CuCl$ and HCl . In all cases the extinction coeff. increases with the increase in temp. of the solns. showing a considerable absorption of light. This may be due to a change of hydration of the solutes at higher temps. In all cases straight lines are obtained by plotting extinction-coeffs. against temps.

E. G. VAN DEN BOSCHE

Photography of the infra-red solar spectrum. H. D. BABCOCK. *Nature* 121, 830 1(1928).—About 12 lines between 10,000 and 10,750 Å. U. have been observed on prismatic plates, one at 10,049.8 Å. U. being especially conspicuous; it is evidently the fourth member of the Paschen series of H. On grating plates a no. of lines were also observed.

B. C. A.

H_α emission in the positive column. E. LAU. *Z. Physik* 48, 824-30(1928).—The intensity and polarization of the H_α line from the pos. column in a discharge tube have been examd. with respect to the gas pressure in the range 0.05-0.7 mm. The observed Stark effect is of the same order as that calcd. by Sommerfeld's theory.

B. C. A.

Optical characterization of spark emission spectra. G. I. POKROVSKII. *Z. Physik* 48, 586-93(1928).—By assuming that the energy consumed in a spark is proportional to the square of the root mean square value of the current flowing through the arc, the total intensity I of n spectral lines is shown to be related to the current i and to the absorptive power, k , of the metal vapor, through which the spark takes places by the expression $I = ai^3 + b(1 - e^{-koi^2})$, where a , b and c are consts. It is also shown that for a given value of i , I is linearly related to the width of the spark gap. Data relating to lines 5000, 5200, 5890 Å. U. in the spark between Cu and electrodes are shown to be in agreement with the above expression.

B. C. A.

Infra-red reflection spectra of sodium chlorate and sodium bromate. G. LASKI. *Z. Krist.* 65, 607-14(1927).—The characteristic frequency is 25μ for $NaClO_3$ and 23μ for $NaBrO_3$, both substances exhibit absorption between 40 and 120μ , with a max. at 83μ and 82μ , resp. A triangular configuration is postulated for the chlorate and bromate radicals.

B. C. A.

Broadening of hydrogen chloride lines by foreign gases. H. W. KUSSMANN. *Z. Physik* 48, 831-44(1928).—The influence of various indifferent foreign gases has been investigated by absorption measurements, a quartz lens method of focal sepn. being used. A, in spite of its at. symmetry, exerts a strong influence, so the broadening is supposed to be due, not to an intramol. effect, but to Lorentzian collision damping. Hence for any single foreign gas the absorption change brought about by the broadening

of the line is proportional to the increase in the no. of collisions, but this proportionality factor differs with different gases. B. C. A.

Structure of Fraunhofer lines and quantitative spectrum analysis of the atmosphere of the sun. W. ANDERSON. *Z. Physik* 48, 447-8(1928).—The assumption made by Unsöld (C. A. 22, 1277) that when the partial pressure of free electrons in the chromosphere is 10^{-4} atm. the latter still shows a continuous spectrum is held to be irreconcilable with observation. B. C. A.

The retarded luminescence observed in the air. WITOLD BERNHARDT. *Bull. intern. acad. Polonoise* 1928, No. 3A, 69-83.—A relation exists between the retarded luminescence in the air and the pos. pole. The drop of potential on the free path of the mol. plays a decisive role in the formation of mols. capable of giving this luminescence. New types of green retarded luminescence in air have been obtained under varying pressures from 0.01 mm. up to 170 mm. The coloration varies from a clear green to an emerald green. A yellow exists under a pressure of 30 to 40 mm. of Hg. The duration of the green luminescence diminishes with pressure. The spectra of all these types are continuous. The limits of temp. are -130° and $+200^{\circ}$. L. D. ROBERTS

Fluorescence of mercury vapor. H. NIEWODNICZANSKI. *Z. Physik* 49, 59-72 (1928).—The spectrum of the fluorescence radiation emitted by superheated Hg vapor excited by an Al spark has been investigated over the temp. range $245-910^{\circ}$. The bands generally became weaker with rising temp., except the continuous band with an intensity max. at about 3300 Å. U., which attains a max. intensity at about 500° . In the presence of H all the lines and bands were much weaker, except the band with a long-wave convergence frequency of 2349 Å. U., of which the intensity remained unchanged. From the data obtained the carriers of the bands are deduced. The decrease in the intensity of the band with a convergence frequency of 2349 Å. U. with increasing vapor d. in the satd. vapor is attributed to increased band absorption. B. C. A.

Studies on fluorescence and photosensitization in aqueous solution. I. Introduction. W. WEST, R. H. MÜLLER AND E. JETTE. New York Univ. *Proc. Roy. Soc. (London)* A121, 294-8(1928).—Certain ions suppress the fluorescence of various chemically dissimilar compds. in aq. soln. in a definite order, which is identical with the order of the ionic deformabilities. Also, when a photochem. sensitizer is fluorescent, the fluorescence is diminished by the addn. of the reactant; moreover, the addn. of ions suppresses the sensitizing power of a fluorescent sensitizer in the same order as it suppresses the fluorescence. Finally, a non-fluorescent sensitizer is affected in the same way by the addn. of ions. The whole group of phenomena can be simply explained in terms of the hypothesis of "collisions of the second kind," and parallels similar phenomena found in gaseous fluorescence and sensitization. The fluorescent mol. assumes a higher energy state by the absorption of light; it may become deactivated by reradiation (fluorescence) or by transfer of its energy by collision with ions, causing polarization of the ions (extinction by ions), or it may polarize the mol. with which it collides so completely as to disrupt it (photochem. sensitization). II. Fluorescence in aqueous solution. E. JETTE AND W. WEST. *Ibid* 299-312.—A detailed examn. of the effect of ions on the fluorescence of aq. soln. of quinine bisulfate, uranine and uranyl sulfate. The intensity of fluorescence was measured by a balanced photoelec. cell method. For these substances the extinguishing effect is assocd. with the anion, Ag^+ being the only cation with an appreciable effect. Li^+ , Na^+ , K^+ , Rb^+ , Mg^{++} , Hg^{++} and La^{+++} salts were examd. The order of the anions is $\text{I}^- > \text{CNS}^- > \text{Br}^- > \text{Cl}^- > \text{Ox}^- > \text{Ac}^- > \text{SO}_4^{--} > \text{NO}_3^- > \text{F}^-$. The series is identical with the deformability series of the anions, as measured by mol. refraction and dispersion and is closely related to the Hoffmeyer series. III. Photosensitization and fluorescence. R. H. MÜLLER. *Ibid* 313-7.—The quantum efficiency for the photolysis of oxalic acid in presence of UO_4^{++} ion approaches unity at a ratio of $\text{H}_2\text{Ox}/\text{UO}_4^{++}$ of 1:1 and remains const. for higher ratios. The fluorescence of UO_4SO_4 , which was measured by photoelec. cell and amplifier, diminished with increasing addns. of H_2Ox , reaching zero at the same mol. ratio. The rate of decompn. of the H_2Ox is diminished by the addn. of ions, in the order $\text{I}^- > \text{CNS}^- > \text{Br}^- > \text{Cl}^-$ in the same order as the fluorescence of UO_4SO_4 is affected by ions. The same order holds for the inhibition by these ions of Eder's reaction sensitized with Fe^{+++} ion. W. WEST

Action of light on acetylene. H. REINICKE. *Z. angew. Chem.* 41, 1144-6(1928).—Carefully purified and dried C_2H_2 is not changed by daylight or sunlight either in glass or quartz. Polymerization occurs under the action of rays from Hg vapor light with

wave lengths under 300μ , at atm. or higher pressure and at room temp. without sepn. of C, giving an amorphous hydrocarbon insol. in most org. solvents. O_2 and moisture disturb the process, the latter causing the formation of aldehyde. F. C. H.

Photochemical studies. VIII. The photochemical decomposition of malonic acid both in the presence and absence of uranyl sulfate. WILLIS C. PIERCE, A. LEVITON AND W. ALBERT NOYES, JR. Univ. of Chicago. *J. Am. Chem. Soc.* 51, 80–89 (1929).—P., L., and N. find that, at least in the early stages of the reaction, the products of decompn. are almost exclusively CO_2 and $AcOH$, both in the presence and in the absence of the catalyst. With unvaried malonic acid concn., increase in the uranyl sulfate concn. causes the rate to approach an approx. const. value. For av. wave length $250m\mu$, the quantum efficiency of the uncatalyzed reaction is 0.73 (± 0.25); for the catalyzed reaction at av. wave length $290m\mu$, the quantum efficiency is 0.27 (± 0.02); at av. wave length $320m\mu$, it is 0.025 (± 0.04). With const. concn. of uranyl sulfate, the reaction rate increases with increase in the concn. of malonic acid and is found empirically to be proportional to the cube root of the latter quantity. No evidence is found to indicate strongly the existence of a light-sensitive complex, nor does it seem that ionization plays an important part. Several mechanisms and equations therefrom derivable are discussed. WILLIAM E. VAUGHAN

The photoexpansion of chlorine. W. H. MARTIN, A. F. W. COLE AND E. E. LENT. Univ. of Toronto. *J. Phys. Chem.* 33, 148–53 (1929).—Careful purification and drying of Cl_2 do not cause expansion on exposure to light to be greatly lessened. Such Cl_2 shows no abnormal scattering nor any fluorescence visually or photographically. The results do not accord with assumptions published on the theory of photochem. reactions involving dry Cl_2 . RAYMOND H. LAMBERT

The hydroxyl radical in flames. K. TAWADA AND W. E. GARNER. *Nature* 122, 879–80 (1928).—The infra-red radiation from hydrogen flames is usually ascribed to the H_2O mol. (Paschen, *Ann. Physik. Chem.* 52, 214 (1894)). The 3064 A. U. band, present in spectra of H_2 flames, is doubtlessly emitted by the OH radical. That some of this infra-red emission from the flame may be due to OH present in H_2O vapor at high temp. is shown by T. and G. The total radiation from flames of H_2 and O_2 with varying compn., emitted through a fluorite window, was measured by a Moll thermopile and a Downing galvanometer (cf. Garner, *C. A.* 22, 1903). A curve for varying compns. is given. Max. emission of radiation occurs for very nearly equal mixt. of H_2 and O_2 . The assumption of the formation of a OH radical would explain these data, and the quantity of radiation will depend on its duration of life. Excess H_2 will diminish av. life of the radical; decrease of radical due to excess O_2 may be due to inelastic collisions (see also Bonhoeffer and Haber, *C. A.* 23, 772). FLORENCE N. SCHOTT

Theoretical considerations in electric tunnel kiln design. J. KELLEHER. *Trans. Am. Electrochem. Soc.* 55, preprint, 5 pp.(1929).—The variables in elec. tunnel kiln design, and the order in which they are detd. are: (1) time-temp. curve for the material; (2) most economical cross section; (3) velocity; (4) length; (5) rate of energy absorption (in each section); (6) furnace temp. (in each section); (7) losses (in each section); and (8) heat input (in each section). A general set of curves is given, but neither details nor an example of the calcns. is included. B. M.

Electric arc-resistance furnaces powered over 10,000 kw. J. CYRUS-SOBOLEWSKI. *Przemysl Chem.* 12, 655-8(1928).—Max. power is obtained by individual regulation of voltage in the 3 phases. A. C. ZACHLIN

Manganese-steel production in the electric furnace. I. J. TRANTIN, JR. *Foundry* 57, 15-9(1929).—Design, chem. analysis, method of alloying, finishing and pouring temps., foundry practice and heat treatment are factors which enter into the production of good Mn-steel castings. In this installment Mn steels are classified according to use, with analyses and phys. properties for each class. Detailed instructions are given for lining a 3-ton Héroult furnace and for making Mn steel in the furnace. These include brick requirements, patching, materials to be charged, placement of charge, time of melting, addns., test procedure, etc. The other factors, except heat treatment (which is only mentioned), are treated in more general fashion. BENJAMIN MILLER

Researches on the high-frequency induction furnace. III. Contribution to the metallurgy of the iron-free induction furnace. FRANZ WEVER and GUSTAV HINDRICH. *Mitt. Kaiser-Wilhelm Inst. Eisenforsch. Düsseldorf* 9, 319-37(1927); cf. C. A. 22, 3609.—Clay-charcoal crucibles could be used for only one melt, because of their temp. sensitivity. Hearths of luting sand (85% silica, 13% alumina) were mechanically rugged and not harmed by high temperature. Corundum hearths (94% alumina plus 3% clay to improve working quality) were not affected by oxidizing slags nor by the highest temps. reached. They are somewhat more sensitive to temp. change than the high-silica hearths. The high-frequency crucible process differs from the orthodox crucible process in that there is no quiescent period to allow non-metallics to come to the top. Clean metal is produced nevertheless; the stirring causes the minute oxide-particles to coagulate. The stirring also promotes the reaction between iron oxide and silica, so that deoxidation takes place without the addition of Mn, Si or Al. With C steels there is actually a gain in Si from the refractory. Since the corundum hearth is not injured by oxidizing slags, it is possible to add the excess oxide required for quant. decarburization. Logs are given for 14 melts, showing that diverse products can be made, which have any desired analysis, with properties as good as those of similar materials made in conventional ways, and with the advantage that cheap scrap can be charged. BENJAMIN MILLER

Electrolytic copper refining. I. F. CHEMNITUS. *Chem.-Ztg.* 52, 981-3(1928).—An elementary sketch, including history, theory, app. and methods. The numerical values given do not apply to present-day American practice. II. *Ibid* 1002-3.—The recovery of values from scrap brass and scrap bronze, the winning of Cu from lean ores, the recovery of Cu from rayon plant waste water (cuprammonium process), and the removal of Cu from Ag-refinery electrolyte are briefly described. B. M.

Production of the heavy metals by the fused-electrolyte method. II. Production of iron, chromium and manganese from oxides and silicates. G. NEUENDORFF and F. SAUERWALD. *Z. Elektrochem.* 34, 199-204(1928); cf. C. A. 20, 872.—Practically carbon-free Fe, steel and pig iron were obtained by using (a) a mixture of Fe_2O_3 and 25% SiO_2 , (b) Fe_2O_3 without admixt., (c) two magnetic iron ores with and without 25% SiO_2 . Different current yields were obtained, depending on the material used. O is split off in melting. Chromite contg. 57.7% Cr_2O_3 , 15-17% Fe_2O_3 , Al_2O_3 and MgO could not be electrolyzed, because the melting temp. was too high. Admixt. of SiO_2 reduced the temp. to about 1475°. Expts. with Fe cathode gave a product contg. 10.9% Cr, and a second product contg. 10.81% Cr and 1.79% C. A C cathode was substituted for Fe because of the melting together of the Fe cathode. With C cathode a product with 39.51% Cr, 49.4% Fe and 7.27% C was obtained. Electrolysis of south Russian Mn ore (69.36% Mn_2O_3 , 2.2% Fe_2O_3 , 9.31% SiO_2) with addn. of 25% SiO_2 , m. 1250°, gave rapid evolution of gas, which prevented the use of large amounts of material. The deposit consisted of Fe with only 0.8% Mn. Apparently decompn. voltages of Mn and Fe oxides are widely apart despite the soly. of both metals in one another. M. M.

Electrolytic zinc production by "Tainton Pring" process. ELLERY R. FOSDICK. *Elec. World* 93, 135-8(1929).—See C. A. 23, 341. BENJAMIN MILLER

Electrolytic solutions. WALTER R. FETZER. *J. Phys. Chem.* 32, 1787-1807(1928).—A cell of the Castner-Kellner type for prep. carbonate-free NaOH

is described. Methods are developed for detg. the constituents of a Na_2S soln. after electrolysis. When electrolysis is carried out at low current d. the only product is Na polysulfide; at higher current d. sulfate and dithionate are formed. When NaSH is electrolyzed the products are $1\text{Na}_2\text{S}_4:2\text{H}_2\text{S}$. The limiting current (l. c.), or the current necessary to liberate S from a soln. of Na_2S or Na_2S_4 , increases at first with the concn. of polysulfide, passes through a max. and decreases toward zero. The l. c. for polysulfide solns. remains unchanged when rotation is increased from 220 r. p. m. to 700 r. p. m.; with Na_2S this change doubles the l. c. Increase in temp. increases the l. c.

E. G. VAN DEN BOSCHE

The calculation of theoretical potentials from thermodynamic quantities. P. DROSSBACH AND G. DEVOTO. *Z. Elektrochem.* 34, 715-6(1928).—Drossbach recalcs. thermodynamically his results given in *C. A.* 23, 42 for the potentials of Na, K and Ca to meet objections raised by Devoto (*Z. Elektrochem.* 34, 326(1928)). DEVOTO replies briefly.

J. BALOZIAN

The influence of a film of moisture on the Volta effect. R. DEAGLIO. R. Scuola Ingeg., Torino, Italy. *Z. Physik* 51, 279-86(1928).—The moist gaseous film surrounding a metallic conductor behaves like a second-class conductor. This effect can be destroyed by drying or by rarefying the surrounding atmosphere. This has, however, no influence on the Volta effect between metals, which therefore cannot be ascribed to the presence of a moist film.

G. CALINGAERT

Structural development of the Deion circuit breaker up to 15,000 volts. R. C. DICKINSON AND B. P. BAKER. *J. Am. Inst. Elec. Eng.* 48, 96(1929). C. G. F.

Field tests of the Deion circuit breaker. B. G. JAMIESON. *J. Am. Inst. Elec. Eng.* 48, 101(1929). C. G. F.

Some photoelectric and glow-discharge devices, and their applications to industry. J. V. BREISLEY AND E. O. ERICKSON. *J. Am. Inst. Elec. Eng.* 48, 118-21(1929).—Brief descriptions of the photoelec. cell, the grid glow tube, and the photo glow tube. The grid glow tube has been applied to the control of oil burners. The change in cond. of the gases is used to turn off the oil if the flame goes out. The photo glow tube has not yet been developed sufficiently to have long operating life, so that it can be used only for intermittent service.

BENJAMIN MILLER

A precision regulator for alternating voltage. H. M. STOLLER AND J. R. POWER. *J. Am. Inst. Elec. Eng.* 48, 110(1929). C. G. F.

Uniting rubber to metal (ROSSMAN) 30. The importance of H (HARKER) 18. High speed steel-crucible versus electric-furnace products (BROPHY) 9. Electric battery charge indicator with hydrometer and temperature scale. LESTER S. KELLHOLTZ and EUGENE J. BARNEY (to Delco-Light Co.). U. S. 1,701,569, Feb. 12.

Storage batteries. GASTON FROMONT. Fr. 643,487, Apr. 1, 1927. Charged plates are covered with spongy products unattacked by the electrolyte, particularly celluloses, pasteboard, etc. Plates thus covered may be preserved dry in the absence of an

Storage batteries. CHARLES H. V. HARDING. Australian 10,747, Dec. 6, 1927. Cast metal plates which have an active coating so applied that a plate is pos. on one side and neg. on the other are clamped together but sepd. from one another by insulating flanges of hard rubber, etc., so that the spaces between the plates form the container for the electrolyte.

Storage batteries. ACCUMULATEURS EDISON. Fr. 643,445, Nov. 7, 1927. The series connection between 2 neighboring elements is made by a U-shaped iron having claws at its ends which enable it to be fixed to the 2 electrodes.

Storage battery. DEUTSCHE ELEMENTE FABRIK A.-G. Ger. 469,736, Nov. 27, 1926. Double storage batteries are formed with concentric cylindrical electrodes.

Storage batteries. I. G. FARBENIND. A.-G. (H. Rötger, inventor). Ger. 469,917, Dec. 9, 1926. The active mass of electrodes for storage batteries having alk. electrolyte

contain finely divided metal such as Fe or Ni obtained by the decompn. of the corresponding carbonyls.

Storage battery electrodes. E. PARVILLE ET CIE. Brit. 292,122, June 14, 1927. Rods of active material are enclosed in sleeves of wood. Various structural details are described.

Calomel electrode cell. DONALD S. HAKE. U. S. 1,700,796, Feb. 5. A cell is specified having an inlet tube near its upper end for the introduction of KCl soln. and a contact tube extending from the cell at a point below the inlet, and with the end of the inlet tube extending into the contact tube.

Electrodeposition of chromium. J. F. K. McCULLOUGH and B. W. GILCHRIST (to Ternstedt Mfg. Co.). Brit. 292,094, June 13, 1927. A bath is used contg. chromic chloride and alkali or alk. earth metal salts such as KCl, NaCl and NH_4Cl . NaF, oxalic acid and HNO_3 also may be added. An anode of Cr or a sol. Cr compd. is used with a voltage of 8-12 and a c. d. of 250-1000 amps. per sq. ft. of cathode surface.

Electrolysis. ÉTABLISSEMENTS SINGRÜN. Fr. 642,713, Mar. 25, 1927. In aq. or igneous electrolysis by means of a. cs., in addn. to the main electrodes, supplementary electrodes at zero potential are used, and may surround the main electrodes. If the main electrodes are sol., the auxiliary electrodes are of the same nature.

Electrolytic apparatus with annular cells in stacked relation arranged at right angles to a hollow rotatable shaft. ILIHU THOMSON (to General Electric Co.). U. S. 1,701,346, Feb. 5. An app. is specified which is adapted for producing H and O from H_2O .

Electrolytic cell for generating gases from alkaline electrolytes. MONTECATINI SOC. GÉNÉRALE PER L'INDUSTRIA MINERARIA ED AGRICOLA. Brit. 292,130, June 11, 1927. Cu supply bars are plated with Ni to protect them from the electrolyte. Various structural details are described.

Apparatus for the electrolytic production of sheet or other form of metal from ores or other raw material. FIRMA J. C. F. A. SCHÜTTE. Ger. 469,931, Dec. 30, 1925. The ore is stored between 2 circular walls, one of C sticks, the other of perforated C plates. Cf. C. A. 22, 3847; 23, 1065.

Aluminum. ELEKTRIZITÄTWERK LONZA. Fr. 641,140, Sept. 16, 1927. Al_2O_3 in a state suitable for the production of Al by electrolysis is obtained by sudden chilling in water of molten Al_2O_3 .

Aluminum. SOCIÉTÉ ANON POUR L'INDUSTRIE DE L'ALUMINIUM. Fr. 642,664, Oct. 21, 1927. Pure Al is prepd. electrolytically using a solid anode of the material to be refined and a solid cathode, both in a bath contg. halogenides of Al and of alkalies or alk. earth metals and a salt or oxide such as Al_2O_3 , Mg oxide of Fe, NH_4Cl , PbCl_2 or salts of Mg, Fe, Pb, Cd, Ni or Mn, which facilitate the obtainment of a dense deposit on the cathode. The salt used may be incorporated in the anode. Cf. C. A. 23, 1065.

Plating tools. COMPAGNIE FRANÇAIS POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 642,846, Oct. 6, 1927. Cutting tools have their edges improved by an electrolytic deposit of Cr. A c. d. of 0.1 amp. per sq. cm. or more is used between an anode and a cathode formed by the tool, and the latter is kept in rotation. The bath may be agitated and air bubbled through. A preliminary treatment may be given in which the tool forms the anode.

Electrometallurgy. ARTHUR DOSSMANN. Ger. 470,200, Jan. 15, 1926. In a device for the extn. of metals deposited by galvanic or other elec. methods, the contact between the electrode clamps for the metal is improved by a transverse bar connecting the current leads.

Electric control device for pressure, temperature and humidity regulators, etc. H. J. NORBALLE. Brit. 292,670, March 21, 1927.

Gas purification. METALLGESELLSCHAFT A.-G. (Arno Nättcher and Franz Seipp, inventors). Ger. 469,780, Feb. 27, 1926. In the elec. removal of suspended matter from gas, the gas is led through a helical chamber contg. the elec. field and out at the axis of the helix.

Gas purification plant. METALLGESELLSCHAFT A.-G. and ILSE, BERGBAU A. G. Ger. 470,109, June 22, 1926. The outlet pipe contains an elec. dust-catching device divided by a partition, and is closed by a pair of covers with adjustable closing plates.

Shaker for the electrodes of a gas purification plant. SIEMENS-SCHUCKERTWERKE A.-G. (Franz J. Mosch, Curt Gerhardt, inventors). Ger. 469,909, Aug. 24, 1927.

Carbon electrodes. IMRE SZARVASY. Austrian 111,831, Aug. 15, 1928. The tarry products obtained by the thermal decompn. of natural gas are coked, preferably in a stream of CH_4 dild. with H, before being worked up in the usual way. The gas carbon also obtained may be mixed with the coked product or worked up alone. Cf. C. A. 22, 3101.

Incandescent cathode. SIEMENS-SCHUCKERTWERKE A.-G. Fr. 643,378, Nov. 5, 1927. A cathode with high emission power contains besides a compd. of an alk. earth metal, one or more alk. earth metals in metallic form.

Coating cathodes to prevent development of excess voltages in working. A. VOGEL. Brit. 292,131, June 14, 1927. Cathodes are provided with colloidal or finely divided metal or metallic compds. (suitably after roughening or covering with wire gauze). The material may be formed by preliminary anodic oxidation of the electrode material, e. g., iron. The working anode may be formed of Ni.

Electric induction furnace. MICHAEL SURJANINOFF. Fr. 643,020, Oct. 26, 1927.

Electric resistance furnace. J. L. MCFARLAND (to British Thomson-Houston Co., Ltd.). Brit. 292,165, June 16, 1927. Structural features.

Electric annealing furnace with wire or strip resistances. SIEMENS-SCHUCKERTWERKE A.-G. Brit. 292,139, June 15, 1927. Structural features.

Regulable electric heater for laboratory purposes. HERMAN GOLDBERG (to Precision Scientific Co.). U. S. 1,702,078, Feb. 12.

Oven. ÖSTERREICHISCHE SIEMENS-SCHUCKERTWERKE. Austrian 111,545, July 15, 1928. An electrically heated oven is described into which the materials to be warmed or strongly heated are fed by a horizontal conveyor which transfers them to a vertical conveyor. The latter carries the materials through the hottest zone of the oven and then immediately discharges them through an outlet near the top of the oven on the opposite side to the inlet.

Heating non-metallic molds and castings. ALEXANDER MEISSNER. Ger. 470,196, Jan. 6, 1926. Metal bodies such as plates or disks are placed in the casting or mold and an a. c. is passed through them.

Apparatus for registering electrical processes by means of a layer modified chemically by electricity. SIEMENS-SCHUCKERTWERKE A.-G. Fr. 643,688, Nov. 9, 1927. Elec. valves are placed in the circuit of the electrode to allow passage of the current in one direction only.

Electric deflagrators. WILHELM ESCHBACH and WALTER FRIEDERICH. Fr. 643,706, Nov. 9, 1927. Fulminating material for elec. deflagrators used in mines, etc., is composed of mono- and poly-basic Pb salts of nitrated compds. particularly nitrophenols with 2 or 3 nitro groups, having a short flame duration which will not light mixts. of CH_4 and air. Cf. C. A. 22, 3532.

Continuously loaded submarine cable. ARCHIE R. KEMP (to Western Elec. Co.). U. S. 1,700,766, Feb. 5. A continuously loaded submarine conductor is impregnated with a filling material such as liquid bitumen which is fluid at the temp. and pressure at which the conductor is to be used; a reservoir of the material surrounds the impregnated conductor.

Luminous electric tubes. "OSA" PARTICIPATIONS INDUSTRIELLES (Société Anon.). Fr. 643,960, Oct. 27, 1927. Luminous elec. tubes are filled with a mixt. of CO_2 and a rare gas such as He to obtain an effect comparable with daylight.

Carbon filaments. ANTON LEDERER. U. S. 1,700,901, Feb. 5. See Can. 282,800 (C. A. 22, 4072).

Lamp filaments. SOCIÉTÉ FRANÇAISE DES LAMPES À INCANDESCENCE LUXOR. Fr. 643,554, Apr. 11, 1927. See Brit. 288,557 (C. A. 23, 571).

Filament for incandescent lamps. FRANZ SKAUPY (to General Electric Co.). U. S. 1,701,342, Feb. 5. In order to convert refractory oxides such as Th oxide into a uniaxial structure, the material is provided with a casing of ductile metal such as Cu, Ni or Fe; after drawing to filamentary size an elec. current is passed through the drawn product of sufficient intensity to heat the product and convert it to uniaxial condition; the casing is then removed e. g., by use of HCl.

5—PHOTOGRAPHY

C. E. K. MEES

The representation of the density relations of photographic materials in the form of surfaces. H. ARENS and J. EGGERT. *Z. physik. Chem.* 131, 297-309(1928).—For const. density the relations between $\log I$ and $\log t$ are shown in the form of curves, I and t being intensity and time, resp. When the reciprocity law holds straight lines are obtained. When all 3 parameters, I , t and D , are varied, surfaces may be employed to represent the results; they are of great value. *Alfa Extra-rapid plates* have been studied for an intensity range of $1-10^7$ and a time range of $1-10^6$. R. H. L.

Sensitometry of desensitized layers. H. ARENS AND J. EGGERT. *Z. wiss. Phot.* 26, 111-26(1928).—During this investigation the failure of the reciprocity law was taken in account and three-dimensional curved surfaces were constructed (cf. preceding abstr.) Normal extra-rapid Afga plate was compared with a desensitized plate. The latter was treated with phenosafranine 1:2000 + 2% KBr (desensitized plate). The surfaces given by the normal- and d.-plates were quite different. No single no expressed the degree of desensitizing.

A. P. H. TRIVELLI

The preparation of highly sensitive negative emulsions in the laboratory. KARL KIESER. *Z. angew. Chem.* 41, 1292-5(1928).—The equipment used for making emulsions in the lab. is described. A typical procedure is given for prepg. a fast emulsion by the use of ammoniacal AgNO_3 and NH_4 halides. Long digestion at a low temp. is more easily controllable than a short digestion at a high temp. A rapid and efficient method of washing to remove sol. salts may be carried out by flowing the emulsion in a thin film over the wall of a large flask and chilling, whereby it may be conveniently washed. Ten min. digestion, at 45° , of such an emulsion gives a speed of about 100 H. and D. The limit of speed depends on the gelatin used. Coating of plates, chilling and drying are all described. Preliminary treatment of plates is also mentioned.

R. H. LAMBERT

Artificial sensitization of emulsions with metallic nuclei and the theory of photographic light-sensitivity. A. STEIGMANN. *Phot. Ind.* 26, 1062-3(1928).—It is suggested that artificial sensitization with adsorbed metallic nuclei according to methods of Genisch and natural sensitization from ripening nuclei may involve different explanations.

C. F. MEULENDYKE

Topography of the nuclei. LÜPPO-CRAMER. *Kinotechnik* 10, 555-6(1928).—The latent image on fast bromide plates is apparently destroyed by bathing in weak chromic acid when given normal development. Schmidt states that with fixation and development in a phys. developer, such a plate suffers only a 10° Eder-Hecht reduction in speed. L.-C. claims that the first effect is due to the absorption of the chromic acid and inhibition of development. Fixation removes the occluded acid and leaves the nuclei for phys. development. A few nuclei are dislodged in the process and account for the loss in speed.

H. C. CARLTON

Nuclei isolation and fog formation. LÜPPO-CRAMER. *Kinotechnik* 10, 612-6(1928).—Various emulsions were given a graduated exposure and then bathed in a soln. with 1% KBr, 1% AcOH and a group of substances as the third constituent, and then washed and developed. The desensitizers, phenosafranine and pinakryptol green, gave bleaching of the latent image which is ascribed to isolation of the nuclei. Methylene blue, however, gave some bleaching action and fogging simultaneously. Hypo and K thiocyanate behave in the same way as the desensitizers.

H. C. C

Practical cinematographic tests. A. P. RICHARD. *Cinemat. franç.* 10, 127-8(1928).—A 7-step color tablet composed of white, red, yellow, light green, green, blue and black color bands is used as an exposure test for the color sensitivity of an emulsion. The emulsions tested were developed for varying times in metol-hydroquinone and glycine developers. Some of the tests indicate that glycine developer is superior to other developers, particularly metol hydroquinone. Having obtained similar results on check tests with glycine, R. suggests that glycine developer be more widely used.

D. E. HYNDMAN

The fibrous structure of silver bromide in photographic dry plates. HANS H. MEYER. *Ann. Physik* 86, 325-52(1928).—The relative intensities of the lines of the x-ray diffraction pattern (Debye and Scherrer) of the AgBr emulsion of a high-speed photographic dry plate were affected by preferred orientations among the AgBr grains. Photographs made by passing the x-rays through the sample parallel to the gelatin layers gave a typical x-ray fiber diagram, and analysis of the patterns showed a strong preponderance of the octahedral planes parallel to the gelatin layer. Similar exposures made on the plain dried gelatin gave the fiber diagram characteristic of stretched gelatin. A slow fine-grained emulsion gave a much less pronounced fiber diagram. As shown by calculation by Silberstein in 1921, AgBr grains in the form of flat plates are brought parallel to the plate by the shrinkage of the gelatin thickness during drying; it is known that these plates are generally parallel to the octahedral planes of the crystal.

R. B. WILSEY

Determination of the sensitivity of color-sensitive plates. A. HÜBL. *Phot. Ind.* 26, 758-9, 901-2; *Camera (Luzern)* 7, 59-62; *Phot. Korr.* 64, 229-31, 265-71, 299-302, 332-5(1928).—A simple method of detg. tricolor (threshold) sensitivity ratios. A strip of the color-sensitive plate is exposed, together with a strip of an ordinary plate of which the Scheiner sensitivity (to the Hefner lamp) is known, in an Eder-Hecht

sensitometer, to Mg light. H. points out the need for more powerful color sensitizers, particularly in the red, to facilitate cinematography by artificial light; he believes that such sensitizers are to be found.

E. R. BULLOCK

Silver halide pseudomorphs. LÜPPO-CRAMER. *Phot. Korr.* 64, 297-9(1928).—It is shown that AgBr produced by the action of KBr soln. on grains of AgCl adsorbs phenosafranine and certain optically sensitizing dyes more strongly than does the untreated AgCl, or than does AgBr produced directly from AgNO₃ as in a pure bromide emulsion. The effect (which is not invariable) is attributed to the large internal surface of the (porous) pseudomorphs of AgBr after AgCl.

E. R. B.

Herschel effect with copper and iron salts. LÜPPO-CRAMER. *Kinotechnik* 10, 407-8(1928).—Carroll's results relative to the sensitizing of emulsion to red light with Fe and Cu salts have been checked by L.-C. Some paper emulsions show considerable bleaching of the latent image with red or yellow light but this is enhanced by the presence of Fe or Cu salts. These may be introduced by addn. of the emulsions before coating or by bathing after the exposure has been made. Like strong desensitizers, they destroy the latent image in the absence of bleaching light if present in too high concn.

H. C. CARLTON

Photography. GEOFFREY WHEELER. *Ger.* 469,811, Jan. 13, 1927. See *Brit.* 271,578 (*C. A.* 22, 1552).

Color photography. M. AUDIBERT (to S. de Procaudine-Gorsky). *Brit.* 293,038, June 30, 1927. Each of the component color-record pos. images which are superimposed to produce a multicolor photograph is colored by immersion first in an iodized soln. to convert the metallic Ag of the image completely into AgI and then in a stable bath contg. a basic aniline dye of appropriate color and also Na hyposulfite so that a partially tanned image in colored gelatin free from Ag results. A tanning developer such as pyrogalllic acid is preferably used. Various details are given.

Optical systems for color photography. SOCIÉTÉ CIVILE POUR L'ÉTUDE DE LA PHOTOGRAPHIE ET DE LA CINÉMATOGRAPHIE EN COULEURS. *Brit.* 293,047-8, June 30 and July 1, 1927.

Photography without plates. JOSEPH ALBANES-VILARO. *Fr.* 642,733, Mar. 26, 1927. A photographic paper for the direct production of positives has an emulsion similar to that of AgBr papers in which the base of AgBr is raised to the max. and the layer of BaO used for sizing the support is reduced to a min. The first developing bath is composed of genol 10, hydroquinone 15, Na₂S 100, Na₂CO₃ 80 g. in 1000 cc. of water. The inversion bath is composed of K₂Cr₂O₇ (satd. soln.) 500 cc., sulfochrome 10 g., HNO₃ 25 g., alc. 200 cc. and water 1000 cc. The sulfochrome is made by mixing 100 g. of K₂Cr₂O₇ or NH₄ in 10 cc. of water and 50 cc. of H₂SO₄ and drying. The second developing bath is the same as the first with the addn. of 10% of a 20% soln. of KBr.

Photographic antihalation plates. I. G. FARBENIND. A. G. *Brit.* 292,990, June 29, 1927. A coating for the backs of plates is formed by adding to an alk. casein soln., CH₃O and a coloring material such as acid black 2B, nigrosin D sol. in water, wool black 4B or lampblack.

Desensitizing photographic plates and films. I. G. FARBENIND. A. G. *Brit.* 292,140, June 15, 1927. Plates or films coated with AgBr emulsion are desensitized by treatment with an isophenosafranine which does not stain the fingers or clothes of the operator. A dil. soln. of 1, 3- (or 2,3-) isophenosafranine may be used.

Films. PALMIRE H. NICOLIC and MAURICE JEAN EDMOND CLAUDE. *Fr.* 635,828, Oct. 5, 1926. A deposit of metal or conducting metal salt is applied either on the edges and on the spaces between the images or on the whole surface of cinematographic films, or a layer of radioactive substance between 2 metallic layers may be used to prevent accumulation of static electricity.

Films. PALMIRE H. NICOLIC and MAURICE J. E. CLAUDE. *Fr.* 33,191, Nov. 17, 1926. Addn. to 635,828 (cf. preceding abstr.) A deposit of metal or conducting metal compd. is applied on the back and sides of a film so that the whole film is enclosed in a conducting layer, whereby accumulation of static electricity is prevented.

Photographic films. AKTIENGESSELLSCHAFT FÜR FILM-FABRIKATION. *Ger.* 469,810, June 9, 1928. Photographic films are dipped for about a min. into a dil. HCl bath before developing.

Photographic reversal films. I. G. FARBENIND. A. G. (Erwin Mankenberg, inventor). *Ger.* 469,968, Mar. 20, 1927. Photographic films are developed to produce thereon, by reversal, positives having the correct gradation by subjecting the film after exposure to a short development fixed for the particular film material, re-

the image in known manner by dissolving out the Ag image, treating the film

in a clearing bath, exposing to light and re-developing. The density of the resulting positive is reduced by means of a reducing bath comprising a mixt. in the proportion of 8:100 of the following (A): 1 g. I, 2 g. KI in 200 cc. water; (B) 4 g. thiocarbamide in 100 cc. water. This reducing bath may also be used for dissolving out the Ag image produced by the first development.

Cinematograph film material. JOHN E. THORNTON. U. S. 1,700,617, Jan. 29. A positive film material comprises a strip of waterproof material such as celluloid of double standard width and half standard thickness, a layer of colored colloid in 2 parallel differently colored stripes on 1 side of the strip and a layer of differently colored colloid in 2 parallel stripes on the other side of the strip; the strip is adapted to receive 4 component image impressions and then to be severed and reassembled by cementing. U. S. 1,700,618 specifies a strip of film material for production of color pictures comprising a transparent support having 2 filter-screens arranged side by side, each screen having 2 colors and being covered by a layer of panchromatic emulsion.

Photographic emulsions. I. G. FARBERNIND. A.-G. Fr. 33,152, Jan. 17, 1927. Addn. to 620,935. A gelatin for photographic emulsions of Ag salts contains products of decompn. of animal or vegetable proteins formed by alk., fermentative or acid hydrolysis accompanied by a partial oxidation.

Dyes suitable for sensitizing photographic emulsions. KODAK, LTD. Brit. 292, 374, July 28, 1927. Dyes effective for sensitizing photographic emulsions to that portion of the spectrum from about 740μ to about 1100μ are made by the action of a strong base, such as NaOH and CHI_3 , upon a quaternary NH_4 salt derived from lepidine or from a lepidine deriv. substituted in the benzene nucleus such as lepidine ethiodide or other lepidine alkyl halide, etc.

Photographic toning agent. SOCIÉTÉ INDUSTRIELLE DES APPLICATIONS CHIMIQUES ("I. N. D. A. C"). Fr. 643,264, Nov. 2, 1927. Na_2S is prepd. c. p. for use as a toning agent by treating it with steam under pressure in an autoclave to liquefaction, followed by a purification with terinoline, decanting, filtering and washing with NaOH soln.

Treating photographic prints. J. HALDEN & CO., LTD. and JOSEPH B. HALDEN. Fr. 643,401, Nov. 5, 1927. Prints are developed, washed and otherwise treated while on an endless band passing over rollers in a circuitous path from one end of a machine to another with jets of liquid of sufficient force to keep the print on the band.

Negatives for photomechanical printing processes, etc. WILLIAM HEINECKE. U. S. 1,700,262, Jan. 29. A sensitized material is provided with an ink impression, as by use of an engraved plate or electrotpe, and after development the impression is removed, e. g., by a KHCO_3 soln.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Study of germanium. I. Treatment of germanite, preparation of pure germanium dioxide and the purest germanium tetrachloride. L. DEDE AND W. RUSS. *Ber.* 61B, 2451-9(1928).—The germanite available is a *copper thiogermanate* with a variable content of Fe, Zn and other elements. A typical analysis would be about 44% Cu, 30% S, 8.7% Ge, 4% As, 2.7% Zn, 5-6% Fe and 1-2% Pb. The mineral is decomposed and analyzed by Kriesel's method (*C. A.* 19, 949). For purification of the Ge from As, the decompn. of the finely powdered mineral is accomplished with a mixt. of HNO_3 , H_2SO_4 and H_2O in the proportions of 50:20:50 parts by vol. The GeO_2 in the residue is nearly free from As, but further purification is best obtained by means of the easy vaporization of GeCl_4 from HCl solns. of GeO_2 : $\text{GeO}_2 + 4\text{HCl} = \text{GeCl}_4 + 2\text{H}_2\text{O}$. The GeCl_4 is passed into H_2O , hydrolyzing it again to GeO_2 ; this is quite pure except for a small Cl content. Pure GeCl_4 is prepd. by heating GeO_2 in a stream of HCl gas. The HCl contamination is removed by sucking dry air through the tetrachloride, the last traces are removed by standing for 12 hrs. over anhydrous Na_2CO_3 . B. p. is 83° . II. **The action of carbon tetrachloride upon germanium dioxide.** *Ibid* 2460-3.—The vapor of boiling CCl_4 is allowed to pass over GeO_2 , or a mixt. of inert gas and CCl_4 is caused to react with GeO_2 . The latter method is preferable. The reaction is studied with variation in temp. and time, appreciable reaction taking place already at 500° . The results are tabulated and velocity is plotted against temp., showing that the reaction velocity increases very rapidly with increase in temp. At 500° for 203 mins. the relative velocity is 0.010, and at 865° for 72 mins. the relative velocity is 47.95. The curve giving the relation between velocity and temp. is a parabola. The reaction is expressed by the equations:

$\text{GeO}_2 + \text{CCl}_4 = \text{GeCl}_4 + \text{CO}_2$ and $\text{GeO}_2 + 2\text{CCl}_4 = \text{GeCl}_4 + 2\text{COCl}_2$. The formation of an intermediate GeOCl_2 is not observed.

H. STOERTZ

Oxidation of silver in dilute ammonium hydroxide solutions. K. A. HOFMANN AND ULRICH HOFMANN. Tech. Hochschule, Berlin. *Ber.* 61B, 2566-75(1928).—Finely divided Ag goes into soln. in NH_4OH satd. with O_2 , rapidly at first and then more slowly until the action gradually ceases. Ag powder is prepd. by reduction of AgNO_3 soln. with Zn. The strength of the NH_4OH soln. used is 6.4%, and the Ag in soln. is expressed as AgCl, although the compd. formed is $\text{Ag}(\text{NH}_3)_2\text{OH}$. With about 9 g. of Ag powder in 300 cc. of NH_4OH , the action continues until the concn. of Ag taken up expressed as g. AgCl in 50 cc. is about 0.27, by which time (about 60 days) the action has completely ceased. If the Ag remaining is washed with pure NH_4OH and the expt. repeated, the action continues again but ceases this time at a concn. of about 0.10 g. AgCl in 50 cc. This is reached in about 100 days. Increase in the quantity of Ag powder produces a proportional increase in the amt. of Ag dissolved, as do also additions of NH_4NO_3 , KNO_3 , NaNO_3 and $(\text{NH}_4)_2\text{SO}_4$. Alkalies and halides diminish the soly. while AgNO_3 and AgOH prevent the action entirely. The authors conclude that the slowing up of the reaction is due to the deposition upon the surface of the Ag powder of an insol. and only slowly oxidizable substance which is gradually formed from $\text{Ag}(\text{NH}_3)_2\text{OH}$ and which is identical or related to Berthollet's fulminating Ag compds., Ag_3N , Ag_3NH .

H. STOERTZ

Constitution of hydroxides and hydrates. II. Complex compounds containing water of coordination. G. NATTA. Reale Politecnico, Milano. *Gazz. chim. Ital.* 58, 619-26(1928); cf. *C. A.* 23, 350.—To ascertain the function of water in cryst. lattices, certain hydrates contg. water of coordination or of crystn. were studied, the present paper dealing with the x-ray examn. of the complexes $\text{Co}(\text{NH}_3)_4\text{I}_2$ and $\text{Co}(\text{NH}_3)_4\text{H}_2\text{OI}_2$ by the Laue powder method. Both of these compds. crystallize in the cubic system, with elementary cells contg. 4 mols. with dimensions of 10.88 and 10.84 Å. U., resp. This value of 10.88 agrees with that found by Wyckoff and McCutcheon (*C. A.* 21, 1384), but not with that of Hentschel and Rinne (*C. A.* 22, 1711). The calcd. ds. were 2.83 and 2.81, resp. The 2 compds. have a similar lattice structure, each atom of Co occupying the center of an octahedron, the vertices of which are occupied by the centers of the coordinated NH_3 and H_2O groups which behave as isomorphous groups. The substitution of a mol. of NH_3 by a mol. of H_2O leads to a slight contraction of the lattice which otherwise remains unaltered. An x-ray examn. of this character serves to obtain an insight into the action of so-called secondary valences on the positions of coordinated groups with respect to the coordinating element, and to add further exptl. proof of the theory of Werner.

C. C. DAVIS

The reduction of permanganate ion by chromic ion in acid solution. H. A. FALES AND P. S. ROLLER. Columbia Univ. *J. Am. Chem. Soc.* 51, 345-59(1929).—The oxidation of Cr^{+++} by MnO_4^- in acid soln. at 25° is very slow. It is accompanied by oxidation due to the direct action of Mn^{++++} and the indirect action of Mn^{+++} . Mn^{++++} oxidizes Cr^{+++} rapidly. Mn^{+++} formed from $\text{Mn}(\text{HSO}_4)_2$, acts indirectly as a result of its decompn. into Mn^{++++} . Mn^{++} , by reducing Mn^{++++} to Mn^{+++} , retards the oxidation of Cr^{+++} by MnO_4^- .

LOUISE KELLEY

Double salts. XVIII. The amines corresponding to double oxalates. G. SPACU AND O. VOICU. Univ. Cluj. *Bul. soc. stiinte Cluj.* 4, 154-63(1928); cf. *C. A.* 22, 3106.—By treating $\text{NiC}_2\text{O}_4 \cdot \text{K}_2\text{C}_2\text{O}_4 + 6\text{H}_2\text{O}$ with benzylamine in boiling petroleum

ether, a sky-blue ammine is obtained, $\text{Ni} \left[\begin{smallmatrix} (\text{C}_2\text{O}_4)_2 \\ \text{Bzl}_2 \end{smallmatrix} \right] \text{K}_2 + 2\text{H}_2\text{O}$. This ammine is very stable, a 7 days' exposure in the air fails to alter its compn.; heating liberates H_2O , then benzylamine. $\text{NiC}_2\text{O}_4 \cdot \text{C}_2\text{O}_4\text{K}_2 + 6\text{H}_2\text{O}$ in a boiling alc. soln. of ethylenediamine gives a pink ammine: $[\text{Ni en}_3](\text{C}_2\text{O}_4\text{K})_2 + 3\text{H}_2\text{O}$, sol. in H_2O with decompn., giving a violet color due to $[\text{Ni en}_3]^{+}$. $\text{NiC}_2\text{O}_4 \cdot \text{C}_2\text{O}_4\text{K}_2 + 6\text{H}_2\text{O}$ loses $4\text{H}_2\text{O}$ between 40° and 50° , the fifth between 75° and 125° and the last between 145° and 220° . This indicates that 2 mols. of H_2O are much more tightly bound to the metal than the others, and consequently, are located in the first sphere, the four remaining mols. of H_2O being in the second sphere of the complex. The formula $\left[\text{Ni} \begin{smallmatrix} (\text{C}_2\text{O}_4)_2 \\ (\text{H}_2\text{O})_2 \end{smallmatrix} \right] \text{K}_2 + 4\text{H}_2\text{O}$ is adopted. Two mols. of H_2O of the first sphere are replaceable by benzylamine. Ethylenediamine, being a stronger base, expels the oxalic radicals; besides, the $2\text{H}_2\text{O}$. $\text{CoC}_2\text{O}_4 \cdot \text{C}_2\text{O}_4\text{K}_2 + 6\text{H}_2\text{O}$ treated with benzylamine gives a pink ammine $\text{CoBzl}_2 \cdot \text{C}_2\text{O}_4\text{K}_2 + 2\text{H}_2\text{O}$, stable in air. The formula $\left[\text{Co} \begin{smallmatrix} (\text{C}_2\text{O}_4)_2 \\ \text{Bzl}_2 \end{smallmatrix} \right] \text{K}_2 + 2\text{H}_2\text{O}$ is attributed by reason of analogy. $\text{CoC}_2\text{O}_4 \cdot \text{C}_2\text{O}_4\text{K}_2 + 6\text{H}_2\text{O}$ be-

comes anhydrous at 50°; despite this fact the formula $\left[\text{Co} \begin{smallmatrix} (\text{C}_5\text{O}_4)_2 \\ (\text{H}_2\text{O})_2 \end{smallmatrix} \right] \text{K}_2 + 4\text{H}_2\text{O}$ is postulated by analogy. XIX. Ammines corresponding to double salts of the bromide class. *Ibid* 187-209.—A series of ammines has been obtained by treating $[\text{SnBr}_3][\text{Mn}(\text{H}_2\text{O})_6]$, $[\text{SnBr}_3][\text{Ni}(\text{H}_2\text{O})_6] \cdot 2\text{H}_2\text{O}$, or $[\text{SnBr}_3][\text{Co}(\text{H}_2\text{O})_6] \cdot 4\text{H}_2\text{O}$ with benzidine. When the solvent was abs. alc.: $[\text{SnBr}_3][\text{MnBzd}_6] \cdot 2\text{H}_2\text{O}$, $[\text{SnBr}_3][\text{NiBzd}_6] \cdot 8\text{H}_2\text{O}$, $[\text{SnBr}_3][\text{NiBzd}_6] \cdot 4\text{H}_2\text{O}$ and $[\text{SnBr}_3][\text{CoBzd}_6] \cdot 4\text{H}_2\text{O}$ have been obtained; the quantity of benzidine and the time of reaction determine the number of Bzd mols. in the ammine. These benzidine ammines are cryst. powders, little stable towards air and light. The Mn-ammine is white-beige, Ni- is yellow-green, Co- is pink. All are sol. in, and hydrolyzed by H_2O , decomposed by hot dil. acids, partially decomposed by Me_2CO , insol. in EtOH , MeOH , AmOH , Me_2CO , CHCl_3 and petroleum ether. When the reaction with benzidine was carried out in Me_2CO , $[\text{SnBr}_3] \left[\text{Mn} \begin{smallmatrix} \text{Bzd}_6 \\ \text{Me}_2\text{CO} \end{smallmatrix} \right] \cdot 2\text{H}_2\text{O}$, $[\text{SnBr}_3] \left[\text{Ni} \begin{smallmatrix} \text{Bzd}_6 \\ \text{Me}_2\text{CO} \end{smallmatrix} \right] \cdot 8\text{H}_2\text{O}$ and $[\text{SnBr}_3] \left[\text{Co} \begin{smallmatrix} \text{Bzd}_6 \\ \text{Me}_2\text{CO} \end{smallmatrix} \right] \cdot 6\text{H}_2\text{O}$ have been obtained. The Me_2CO inside the mol. is tightly attached. The compds. are stable crystals, nearly colorless, and have the same soly. characteristics as the benzidine-ammines. When the acetonepentammines are treated with pyridine diluted in Me_2CO , $[\text{SnBr}_3] \left[\text{Ni} \begin{smallmatrix} \text{Bzd}_6 \\ \text{Py} \end{smallmatrix} \right] \cdot 8\text{H}_2\text{O}$, $[\text{Sn} \begin{smallmatrix} \text{Br}_3 \\ (\text{OH}) \end{smallmatrix}] \left[\text{Mn} \begin{smallmatrix} \text{Bzd}_6 \\ \text{Py} \end{smallmatrix} \right]$, $[\text{Sn} \begin{smallmatrix} \text{Br}_3 \\ (\text{OH}) \end{smallmatrix}] \left[\text{Co} \begin{smallmatrix} \text{Bzd}_6 \\ \text{Py} \end{smallmatrix} \right] \cdot 5\text{H}_2\text{O}$ and $[\text{Sn} \begin{smallmatrix} \text{Br}_3 \\ (\text{OH}) \end{smallmatrix}] \left[\text{Ni} \begin{smallmatrix} \text{Bzd}_6 \\ \text{Py} \end{smallmatrix} \right] \cdot 4\text{H}_2\text{O}$ are obtained. The four compds. are yellowish crystals; they are fairly stable and their solubilities resemble those of the parent compds.

ALBERT L. HENNE

The double carbonate of copper and sodium. F. DE CARLI AND P. AGOSTINI. *Atti accad. Lincei* 7, 921-5(1928).—When $\text{Cu}(\text{NO}_3)_2$ soln. is added to a satd. soln. of Na_2CO_3 , NaHCO_3 (or K salt), the double salts $\text{K}_2\text{CO}_3 \cdot \text{CuCO}_3 \cdot 4\text{H}_2\text{O}$ or $\text{Na}_2\text{CO}_3 \cdot \text{CuCO}_3 \cdot 3\text{H}_2\text{O}$ are formed. The Na salt is more easily purified. If the Na salt is heated in trying to dehydrate it, an endothermic reaction takes place at 160° with loss of H_2O and CO_2 . The product is $\text{CuO} \cdot \text{Na}_2\text{CO}_3$. However, in an atmosphere of CO_2 , the salt may be dehydrated; heating at 80° gives the product $\text{Na}_2\text{CO}_3 \cdot \text{CuCO}_3 \cdot 2\text{H}_2\text{O}$, while at 120° the anhydrous salt is obtained. The anhydride is light blue, unstable. Heated from 220° to 230°, it loses CO_2 . This action is reversible. Partial pressures of CO_2 in mm. Hg at the abs temps. given are: 363°, 12.1; 443°, 163.50; 477°, 380.20; 512°, 1175.6. The av. value of Q (from Nernst's equation) is 11,325 Cal., Q being the sum of the reactions (1) $\text{Na}_2\text{CO}_3 \cdot \text{CuCO}_3$ soln. = Na_2CO_3 soln. + CuCO_3 soln. + Q' ; (2) CuCO_3 soln. = CuO soln. + CO_2 gas + Q'' , Q' having been found to be 10,330 Cal., Q'' = 995 Cal. A. W. CONTIERI

Compounds of 2,3-dihydroxynaphthalene with trivalent iron, with aluminum and with arsenic acid. R. WEINLAND AND HERMANN SEUFFERT. *Arch. Pharm.* 266, 455-64(1928).—2,3-Dihydroxynaphthalene yields with FeCl_3 , both in aq. and alc. soln., a blue color. Fe compds. (dark brown-red series) of definite compn. are obtained by the interaction of ferric acetate, 2,3-dihydroxynaphthalene and alkali hydroxide; compds. of the violet series are obtained by interaction of ferric acetate, 2,3-dihydroxynaphthalene and alkali acetate in alc. soln. The tendency of these compds. to crystallize is slight. Among those characterized are: *K tris-2,3-dihydroxynaphthalene ferrate*, $[\text{Fe}(\text{OC}_10\text{H}_7\text{O}_2)_3]\text{K}_3 + 2\text{H}_2\text{O}$, red-brown powder; *NH₄ tris-2,3-dihydroxynaphthalene ferrate*, $[\text{Fe}(\text{OC}_10\text{H}_7\text{O}_2)_3](\text{NH}_4)_3 + 5\text{H}_2\text{O}$, microscopic crystals; *Na tris-2,3-dihydroxynaphthalene ferrate*, $[\text{Fe}(\text{C}_{10}\text{H}_7\text{O}_2)_3]\text{Na}_3 + \text{H}_2\text{O}$, amorphous; *violet bis-2,3-dihydroxynaphthalene ferrate*, $[\text{Fe}(\text{C}_{10}\text{H}_7\text{O}_2)_2]\text{H} + 2\text{H}_2\text{O}$, cryst. powder; *K bis-2,3-dihydroxynaphthalene ferrate*, $[\text{Fe}(\text{C}_{10}\text{H}_7\text{O}_2)_2]\text{K} + 4\text{H}_2\text{O}$, microscopic needles; *NH₄ bis-2,3-dihydroxynaphthalene ferrate*, $[\text{Fe}(\text{C}_{10}\text{H}_7\text{O}_2)_2]\text{NH}_4 + 4\text{H}_2\text{O}$, amorphous; *Na bis-2,3-dihydroxynaphthalene ferrate*, $[\text{Fe}(\text{C}_{10}\text{H}_7\text{O}_2)_2]\text{Na} + \text{H}_2\text{O}$, microscopic leaflets; *K tris-2,3-dihydroxynaphthalene aluminate*, $[\text{Al}(\text{C}_{10}\text{H}_7\text{O}_2)_3]\text{K}_3 + \text{H}_2\text{O}$, rhomboidal plates; *NH₄ tris-2,3-dihydroxynaphthalene aluminate*, $[\text{Al}(\text{C}_{10}\text{H}_7\text{O}_2)_3](\text{NH}_4)_3 + 3\text{H}_2\text{O}$ and $5\text{H}_2\text{O}$, microscopic leaflets; *Na tris-2,3-dihydroxynaphthalene aluminate*, $[\text{Al}(\text{C}_{10}\text{H}_7\text{O}_2)_3]\text{Na}_3 + 2\text{H}_2\text{O}$ and $7\text{H}_2\text{O}$, amorphous white powder; *2,3-dihydroxynaphthalene arsenic acid*, $[\text{As}(\text{C}_{10}\text{H}_7\text{O}_2)_3]\text{H} + 5\text{H}_2\text{O}$, large crystals.

7—ANALYTICAL CHEMISTRY

W. T. HALL

Following the course of the reaction in potentiometric titrations. F. L. HAHN, M. FROMMER AND R. SCHULZE. *Z. physik. Chem.* 133, 390-6(1928).—It may be shown mathematically that in a potentiometric titration the turning point on the titration curve occurs before or after the true end point according as the no. of mols., U , of the substance being titrated, which react with one mol. of the reagent, is greater or less, resp., than 1. This error may be quite appreciable even when U diverges only moderately from 1. By the method previously described (*C. A.* 21, 2626), however, it is possible to calc. from the potentials at various stages of the titration both the true end point and the value of U . B. C. A.

A quick method for making starch solution. JOHN C. BAILAR. *Chemist-Analyst* 18, 14(1929).—Into 100 cc. of boiling water, drop about 20 granules of puffed rice. Boil until these granules disintegrate, cool and decant off the starch soln.

W. T. H.

Production of uniform stains in the Gutzeit test. C. H. MANLEY. *Analyst* 54, 30(1929).—The use of "Gloy" is recommended for attaching the HgCl_2 paper.

W. T. H.

Standard solution of magnesium chloride. BENJAMIN FREEMAN. *Chemist-Analyst* 18, 18(1929).—Sometimes a stock bottle of $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ becomes too pasty to weigh. If the original wt. is known, all that is necessary is to make up a soln. to a definite wt. and use measured vols. to get any desired wt. W. T. H.

Determination and separation of a few metals by rapid electrolysis without mechanical stirring of the electrolyte. NICOLAS VENSOVITCH. Univ. Louvain. *Bull. soc. chim. Belg.* 37, 353-76(1928).—Ag, Cu and Cd can be deposited rapidly and quantitatively without stirring, if the electrolyte is kept boiling. The appearance of the deposit is a criterion for detg. the optimum conditions. A sepn. of Ag from Cu can be accomplished by mechanically studying the nature of the deposits. A. L. HENNE

Microchemical determination of metallic elements. I. Microchemistry of potassium ferrocyanide. (Microchemical determination of zinc.) R. NAKASEKO. *Mem. Coll. Sci. Kyoto Imp. Univ.* 11A, 95-112(1928).—The min. quantity of iron detectable with $\text{K}_4\text{Fe}(\text{CN})_6$ is 1 in 3×10^6 of soln., the optimum acidity being about 0.1 N (strong acid). When solns. of FeCl_3 are added to dil. solns. of ferrocyanides the presence of neutral salts or of acidity retards the development of the blue color. A method for the microchem. determination of Zn is outlined. The soln., which should be free from Fe and Mn, is evapd. and the residue ignited. The residue is treated with 2 cc. of water, 1 cc. of 6 N HCl and 1 cc. of 5 N NH_4Cl ; 0.02 N $\text{K}_4\text{Fe}(\text{CN})_6$ is added dropwise from a buret until the granular ppt. becomes colloidal (formation of $\text{Zn}_2\text{K}_2[\text{Fe}(\text{CN})_6]_3$). The whole is diluted to 10 cc., inserted in a water bath at 60-70°, and kept in the dark for 30 mins., when it is centrifuged. The excess of ferrocyanide in the supernatant liquor is detd. with the aid of a reference table by observing the time required for the development of the blue color when 0.05 mg. of Fe (1 drop of a standard soln.) is added to 5 cc. The amt. of Zn in the sample analyzed is $(a - 500b) \times 0.47$ mg., where a is the number of cc. of 0.02 N ferrocyanide added and b the normality of the excess of ferrocyanide. Acid solns. of $\text{K}_4\text{Fe}(\text{CN})_6$ undergo rather rapid decompn. when exposed to daylight; they deposit Prussian blue. On long keeping, dil. neutral solns. are slowly hydrolyzed

with deposition of ferrous cyanide. II. Microchem. detection of iron with dimethylglyoxime. *Ibid* 113-7.—The tint and depth of color produced on mixing solns. of Fe, H_2S , NH_3 and dimethylglyoxime vary with the order of mixing, but are const. under const. conditions. For the colorimetric detn. of Fe the test soln. is first treated with a freshly prepd., satd. soln. of H_2S to reduce ferric salts. The mixt. is then treated with dimethylglyoxime (1% alc. soln.) and finally with NH_3 . The foregoing and the thiocyanate method are about equally sensitive. B. C. A.

Method for the determination of traces of antimony in copper and its alloys. S. G. CLARKE AND B. S. EVANS. *Analyst* 54, 23-8(1929).—Dissolve 5 g. of metal in 30 cc. of 9 N H_2SO_4 and 15 cc. of concd. HNO_3 . Evap. to fumes, cool and add 150 cc. of water, 15 cc. of concd. HCl and 10 g. of NaH_2PO_3 . Boil 10 mins. to reduce Cu to the cuprous state so that it will not interfere with the Reinsch test. In the absence of any considerable amt. of As, the liquid may be treated at once by the Reinsch method. If, however, a brownish black ppt. of As appears during the boiling with Cu, the liquid must be boiled for 20 mins. longer, cooled somewhat, treated with 20 cc. of benzene to coagulate the As and well shaken. This treatment removes the greater part of the As except when considerable Sn is present. Although As does not interfere with the subsequent colorimetric detn. of the Sb, it tends to weaken the film of deposited Sb in the Reinsch pptn. and cause it to become detached from the Cu. (In the case of a bronze, add 10 g. of oxalic acid at the start, before adding NaH_2PO_3 .) For the Reinsch pptn. it is well to use a piece of pure electrolytic Cu foil about 20×2.5 cm. in size, rolled into a flat spiral, as open as is consistent with its being dropped into the flask containing the soln. Clean by warming gently with 6 N HNO_3 and rinsing with water. Drop it into the soln. so that it stands upright and boil 2 hrs. Then lift the Cu spiral out of the soln. by means of a hooked glass rod, plunge it quickly into a beaker of cold water and then place it in another beaker of diameter only slightly larger than the spiral. Cover with distd. water and at once add 1 g. of Na_2O_2 . After 5 mins. heat gently until the Cu coil becomes darkened with a layer of CuO . This should accomplish the dissolving of all Sb, provided the deposit has been treated promptly. Pour off the soln., rinse the Cu, and introduce a rapid stream of H_2S for 15 sec. Allow to stand on the water bath for 30 mins. and then filter off any CuS and Bi_2S_3 , washing the ppt. with 1% NH_4NO_3 . Add 5 cc. of concd. H_2SO_4 to the filtrate, evap. to fumes, adding a few drops of concd. HNO_3 toward the last. Cool, take up with 15 cc. of water, heat to boiling and allow to cool. Det. the Sb colorimetrically as follows: Into a 100-cc. Nessler tube add successively, in this order: 10 cc. of 1% gum arabic soln., 5 cc. of 20% K soln., 1 cc. of 10% aq. pyridine soln., 1 cc. of 0.1 satd. SO_2 soln. and 60 cc. of 9 N H_2SO_4 . Then add the Sb soln., stir well and compare the color with standards. The standard Sb soln. should contain 0.2764 g. of tartar emetic in 1 l. of 10% H_2SO_4 . The color produced with 10 cc. of this soln. is as deep as can be measured to advantage.

W. T. H.

A sensitive test for cobalt by means of diphenylthiocarbazon. HELLMUT FISCHER. *Wiss. Veröffentlich. Siemens-Konzern* 6 [2], 147-9(1928).—The new reagent employed is an ammoniacal soln. of diphenylthiocarbazon. The test is extremely sensitive and simple to carry out. Modified directions are given for the presence of interfering elements. The presence of Ni does not affect the sensitivity. Co can be detected in metallic Ni samples providing it is present to the extent of 0.1%. F. A. R.

A new method of colorimetric determination of lead. A. D. PETROV. *J. Russ. Phys.-Chem. Soc.* 60, 311-6(1928).— H_2O_2 does not interfere with the tetramethyldiamidodiphenylmethane test and can, therefore, be used in the detection of 1 mg. or more of Pb. In the analysis, PbO_2 was first formed by the addn. of $(NH_4)_2S_2O_8$ to the HNO_3 soln., the PbO_2 was filtered off and washed, then treated on the filter with 0.5-1% soln. of the reagent in an EtOH-AcOH mixt. (5-7 cc. per 1 mg. Pb). A deep blue solution resulted which can be slowly dild. when necessary. Mineral acids (if present as impurities in AcOH) destroy the coloration; the color is at first violet, but changes to red.

B. SOYENKOFF

The influence of cobalt on the determination of manganese in steel. ISABURO WADA AND SHOICHIRO SAITO. *Bull. Inst. Phys.-Chem. Research (Tokyo)* 7, 1002-27 (1928); *Abstracts* 1, 97-9.—The purpose of the paper is to decide whether the presence of Co interferes with the detn. of Mn when it is oxidized to permanganate in HNO_3 soln. with sodium bismuthate and then titrated with a ferrous salt. It is found that the titration of permanganate in the presence of oxidized Co will be correct only when these 2 elements are present, but will be incorrect if a third element, chiefly Fe (NO_3), is present. Consequently, Mn in steel cannot be titrated by this method in the presence of Co. ALBERT L. HENNE

Aluminum in steels. The hydroxide method of separation. WM. KUEBLER, WM. J. SHANEMAN AND J. J. GALLAGHER. *Chemist-Analyst* 18, 6(1929); cf. C. A. 22, 1746.—Treat 2 g. of steel with 6 N HCl, oxidize with HNO₃ and take down to a sirup. Cool, transfer to a dropping funnel and add dropwise to an excess of boiling-hot, 20% NaOH soln. Boil to make sure all Cr is pptd., cool, make up to a definite vol., pipet off half of the soln. and ppt. the Al with (NH₄)₂CO₃. Weigh as Al₂O₃. W. T. H.

Rapid determination of nickel in iron and steel. STEPHEN SOULÉ. *Chemist-Analyst* 18, 7(1929).—The method recommended is the cyanide titration described by Campbell and Andrews in 1895. W. T. H.

Preparation and use of the sodium salt of dimethylglyoxime for determining nickel. JOHN B. CASEY. *Chemist-Analyst* 18, 8(1929).—Add 7 g. of NaOH slowly to 1 l. of hot water contg. 20 g. of dimethylglyoxime. Some chemists prefer this to the alcoholic soln. of the reagent, largely because of the Volsted Act. W. T. H.

Determination of molybdenum in steel. WALTER F. MURRAY. *Chemist-Analyst* 18, 10(1929).—Dissolve 5 g. of steel in 200 cc. of N H₂SO₄, add 3–4 g. of (NH₄)₂S₂O₈ and boil to decompose the excess. Dil. to 400 cc. and sat. with H₂S at about 80°, passing the gas through the soln. for 45 mins. Filter, wash with dil. H₂S soln. and ignite in a crucible. Dissolve the resulting MoO₃ in 10 cc. of 20% NaOH, wash out the crucible, boil the soln. and filter. Dilute the filtrate contg. Na₂MoO₄ to 400 cc. and make barely acid to litmus by adding 6 N HCl. Boil 5 mins., add 15 cc. of 5% Pb(OAc)₂ soln., 25 cc. of 25% NH₄OAc and 5 cc. of concd. AcOH, stirring well after each addition. Keep nearly boiling for 20 mins., filter off the PbMoO₄ ppt., wash with hot water and ignite at a dull red heat, weighing as PbMoO₄. If W is present, det. this element in the usual way, evap. the filtrate to fumes. Dil. with water and boil until all the salts have dissolved. Then add persulfate and continue as in the absence of W. W. T. H.

Gravimetric method for microchemical determination of molybdenum. JOSEPH B. NIEDERL AND EDITH P. SILBERT. *J. Am. Chem. Soc.* 51, 376–7(1929).—To det. Mo in an org. compound, heat 3–5 mg. in a porcelain boat with a drop of HNO₃ and weigh the residual MoO₃. The temp. must not exceed 450°. W. T. H.

An aid in the deposition of copper on aluminum. GEORGE W. BENNETT. *Chemist-Analyst* 18, 8(1929).—Very pure Al sometimes does not work well in Low's iodide method for detg. Cu. The addition of a few drops of H₂PtCl₆ to the soln. or the deposition of a little NH₄Cl on the Al from lab. fumes will overcome this difficulty. W. T. H.

Determination of arsenic in oxide of antimony pigment. G. SIROIS. *Chemist-Analyst* 18, 14(1929).—For small quantities of As, distil off AsCl₃ from 25 g. of sample in the A. O. A. C. method, sat. the distillate with H₂S and weigh as As₂S₃. For larger quantities, treat 1 g. of pigment with 15 cc. of concd. H₂SO₄ and 5 g. of K₂SO₄, at until all traces of S have disappeared, cool, dil. with 20 cc. of water, heat until salts have dissolved, add 20 cc. of HCl and sat. with H₂S. After drying the As₂S₃ treatment with CS₂ and another drying are recommended before weighing. W. T. H.

Determination of sulfur in metallic antimony. CHAS. G. SNYDER. *Chemist-Analyst* 18, 6(1929).—Fusion of 2–3 g. of sample in a 75 cc. Ni crucible half filled with K₂O₂ is recommended. Extract the melt with 100 cc. of water, remove the crucible, add 100 cc. of concd. HCl and 10 g. of tartaric acid and heat till the soln. is clear. Then dil. with 400 cc. of hot water and ppt. with BaCl₂. W. T. H.

Note on the estimation of sulfur in steels and cast irons. N. D. RIDSDALE. *Foundry Trade J.* 39, 466(1928).—To avoid low results in the evolution method, mix 5 g. drillings with 0.5 g. of powdered cream of tartar in a porcelain crucible. Fill the crucible with a mixt. of 95% acid-washed, 40-mesh, calcined sea sand and 5% cream of tartar. Cover the crucible with a slightly larger silica capsule, invert the crucible, and fill in the space between the crucible and edge of the capsule with SiO₂-tartar mixt. Slowly heat to 750° and anneal at this temp. for 20 mins. Cool and evolve as usual, using concd. HCl. Run a blank on the reagents. W. T. H.

Separation and determination of nitrogen in argon. CHS. LEU. Univ. Lausanne. *Helv. Chim. Acta* 11, 761–3(1928).—N cannot be eliminated completely from A by passing over hot Mg or Ca. Only 70 or 40%, resp., is fixed by these metals. Mg + 1% Na and a trace of CaO fix 97–98% of the N passed over it at 850–70°. By re-running, A contg. 1–5% N can be freed to the extent of 2/10,000 N. A. L. H.

Determination of nitrogen by the Dumas method. I. MAREK, M. KRAJČINOVIC AND G. ZALJEŠOV. *Arch. hem. farm.* 2, 169–73; In French, 174(1928).—The modifi-

cation here proposed chiefly affects the tube in which the combustion is effected. The tube is heated electrically by Ni-Cr windings. In the back end of the tube the substance mixed with CuO is heated and partial oxidation is effected. In the central part of the tube, the layer of CuO is made shorter than is customary and consists of 10 in. of CuO wrapped in a spiral of Cu gauze which is fully oxidized at the beginning of the analysis. The front end of the tube contains the usual reduced spiral of Cu gauze. Both of the gauze spirals are wrapped with asbestos thread so that they do not come into direct contact with the glass. J. KUČERA

Formation of complex anions in the presence of free hydrogen ions. FREDERICK G. GERMUTH. *Chemist-Analyst* 18, 3-4(1929).—A table is given showing the amt. of citric or tartaric acid, in terms of the p_H value of the resulting soln., requisite to prevent the pptn. of Zn, Cr, Cu, Al and Fe by NH_4OH . W. T. H.

Modified procedure for the determination of the phosphate ion as magnesium pyrophosphate. N. KRILENKO. *Arh. hem. farm.* 2, 197-205(1928).—In French. The method proposed is a modification of Mme. Marjanović's method for detg. the SO_4 ion in $MgSO_4$ by pptn. with phosphate and weighing as $Mg_2P_2O_7$. To 20 cc. of soln. contg. not more than 0.2 g. of P_2O_5 , add 1 cc. of H_2SO_4 and evap. to dryness. Add 2 cc. of concd. H_2SO_4 and 4-5 cc. of a cold, satd. soln. of $MgSO_4$, stirring until the residue has dissolved completely. Make alk. to phenolphthalein by adding concd. NH_4OH dropwise, after adding 3-5 cc. of satd. NH_4 citrate if any Fe, Al or Ca is present. After 30 mins. dil. with a hot soln. contg. 5% of NH_3 and 5% of NH_4Cl . Decant through a weighed Gooch crucible, treat with more of the ammoniacal- NH_4Cl soln. and repeat the treatment until the liquid does not clarify after 10 mins. stirring. Then transfer all the ppt. to the crucible, wash with 2.5% NH_3 , dry, and ignite to 900° . J. K.

Precision methods for the determination of the chloride ion. Y. N. SLAVYANOV. *J. Russ. Phys.-Chem. Soc.* 60, 355-9(1928).—The Vollhard and Mohr volumetric methods were subjected to critical study and procedures were described which will give very accurate results. B. SOYENKOFF

Detection and identification of specific cations with sodium alizarinsulfonate reagent. FREDERICK G. GERMUTH AND CLIFFORD MITCHELL. *Am. J. Pharm.* 101, 46-52(1929).—The value of sodium alizarinsulfonate as a qual. reagent for U, Pt (ic), Sn (ic), Ti (ous), Al, Bi, Fe (ic), Cr (ic), Cu (ic), Hg (ic) and Tl is shown in tables. W. G. GAESSLER

Reactions of hydrogen peroxide, perborate and peroxides. G. TELLERA. *Boll. chim. farm.* 67, 705-7(1928).—The following tests for detecting H_2O_2 , perborates and peroxides were compared: $K_2Cr_2O_7$, H_2SO_4 and Et_2O (Gawalowski) (I); $K_2Cr_2O_7$, $PhNH_2$ and $(CO_2H)_2$ (Bach); KI, starch soln. and H_2SO_4 (II); $(NH_4)_2MoO_4$ and H_2SO_4 (Denigès); $(HOCHCO_2H)_2$, $(NH_4)_2Fe(SO_4)_2$ and soda (Denigès) (III); $PhOH$ and $FeSO_4$ (Spiro); guaiacol and fresh milk (Japernoux). The expts. carried out with H_2O_2 , $Na_2B_4O_7$ and the peroxides of Na, Ba, Mg and Zn revealed that the tests I, II and III gave the best, because most uniform, results. G. SCHWACH

Volumetric determination of arsine. H. KUBINA. *Tech. Hochschule Brunn* *Z. anal. Chem.* 76, 39-48(1929).—By the action of $HBrO_3$ ($KBrO_3$ and dil. H_2SO_4) AsH_3 can be oxidized to AsO_4^{3-} and the bromate reduced to Br^- . In one procedure recommended, the AsH_3 was absorbed in 25 cc. of 6 N H_2SO_4 contg. 10 cc. of 10% KBr and a considerable excess of $KBrO_3$. After at least 5 mins., the excess BrO_3^- was reduced by a measured vol. of $AsCl_3$ soln. and the excess of the latter titrated with $KBrO_3$ soln. The expts. were made with a gas mixt. of AsH_3 and H_2 . The results were accurate within 2-3%. A better method consisted in allowing the AsH_3 to react with ICl soln., $AsH_3 + 8ICl + 4H_2O = AsO_4^{3-} + 4I_2 + 8Cl^- + 11H^+$. The liberated I_2 was then titrated with IO_3^- soln. in the presence of CN^- by the method of R. Lang. $IO_3^- + 2I_2 + 5HCN + H^+ \rightarrow 5ICN + 3H_2O$. W. T. H.

Excess nitric acid in phosphate determinations. GEORGE L. HOCKENYOS. *Chemist-Analyst* 18, 14(1929).—In soil analysis it is recommended to stop the evapn. while a considerable excess of HNO_3 is present and then neutralize with $(NH_4)_2CO_3$ rather than with NH_4OH . Then add a little HNO_3 and ppt. with molybdate in the usual way. W. T. H.

Dehydration of silica. GEO. L. HOCKENYOS. *Chemist-Analyst* 18, 11(1929).—Treatment of the dehydrated SiO_2 with 5 cc. of concd. acid for 5 mins. followed by the addition of 15 cc. of water is recommended in the analysis of soils. If the dehydrated SiO_2 is warmed with 6 N acid about 1 mg. more of SiO_2 is dissolved. W. T. H.

The chemical action of lime on siliceous materials and on trass. P. MECKE. *Tonind. Ztg.* 52, 1498-9, 1517-9(1928).—The siliceous residue from alum manuf. was

analyzed with H_2SO_4 , with NaOH , with $\text{Ca}(\text{OH})_2$ and with $\text{Ba}(\text{OH})_2$. The first 2 and the fourth give similar results but the low soly. of lime makes its action slow and incomplete. CaO will act on such material to evolve heat in an amount depending upon the phys. condition. Such Ca silicates are, however, readily decomposed by CO_2 . Lime mortar contg. this material or diatomaceous earth on titrating after 6 months required much less acid than in the absence of SiO_2 . F. O. A.

Analysis of mixtures containing acetone, ethyl alcohol and isopropyl alcohol. CHARLES A. ADAMS AND JOHN R. NICHOLLS. *Analyst* 54, 2-9(1929).—Comparative tables are given of the strengths and immersion refractometer readings of aq. solns. of acetone and of some of the lower alcs. If not more than 10% of these substances present in an aq. soln., the d. and refractometer readings are approx. additive factors. The following rapid method serves to detect and det. acetone colorimetrically and the process can be adapted to the detn. of isopropyl alc. To 10 ml. of soln. contg. not more than 0.02 g. of acetone, add 1 ml. of 1% soln. of *o*-nitrobenzaldehyde in 50% EtOH , mix, add 0.5 ml. of 30% aq. NaOH and allow to stand for 15 mins., avoiding strong daylight. Compare the color with that obtained from standards treated similarly. To detect isopropyl alc., add 5 ml. of satd. Br -aq. to 10 ml. of soln. contg. not more than 10% by vol. of the alc. Stopper loosely and allow to stand 3-6 hrs. longer in a cool place. Then test for acetone as above. To det. EtOH and isopropyl alc., the following conditions provide for their oxidation to acetic acid and acetone, respectively, and the detn. of each. To distillate contg. not more than 1.5 g. of EtOH or 3 g. of isopropyl alc., add water to make 100 ml. in a 800 ml. distg. flask. Add an equal vol. of soln. contg. 10 g. of $\text{K}_2\text{Cr}_2\text{O}_7$ and 25 ml. of concd. H_2SO_4 . Stopper and allow to stand 30 mins. Then add an excess of FeSO_4 and steam distil until the vol. of liquid in the flask is reduced to 100 ml. Titrate the AcOH in the distillate, using phenolphthalein as indicator and 10 g. of NaCl to make the end point sharper. Distil the neutralized soln. and det. the acetone content by a d. detn. (see following abstract). W. T. H.

The specific gravities and immersion refractometer readings of dilute mixtures of acetone and water. JOHN R. NICHOLLS. *Analyst* 54, 9-11(1929).—Tables are given showing the sp. gr. and refractometer readings of acetone solns. contg. 0.2-10 g. of acetone. W. T. H.

Color reaction of diphenylamine and its application to the identification of this substance in powders. LOUIS DESVERGNES. *Ann. chim. anal. chim. appl.* 11, 1-4(1929).—In alc. soln. a violet color is obtained by the action of Cl_2 on diphenylamine. The test serves to detect 1 part of the amine in 65,000 parts of soln. To detect this substance in a powder contg. about 1.5%, digest 2.5 g. of the powder with 20 cc. of pure ether. After 2-3 hrs. and frequent shaking in a glass-stoppered bottle, filter, add 20 cc. of water to the filtrate and heat to remove the ether. Cool, add 10 cc. of EtOH and some Cl_2 aq. The first addition of Cl_2 serves to destroy the yellow color of the soln. and afterwards the violet color characteristic of diphenylamine appears. Thus with 10 drops of satd. Cl_2 water, the soln. remains yellow even after standing 6 hrs. but with 15-25 drops, the violet color is discernible within 30 mins. W. T. H.

Rapid test for detecting glycerol. STEPHEN SOULE. *Chemist-Analyst* 13, 8(1929).—Drop a little upon a hot piece of Fe . The odor of acryl aldehyde indicates glycerol. W. T. H.

A new acidimetric method for the determination of glucose by means of Fehling solution. MICHAEL DIMITROFF HADJEFF. *Agr. Chem. Inst. Univ. Sofia. Z. Untersuch. Lebensm.* 55, 615-8(1928).—The Cu_2O is pptd. by use of the Meissl-Allihn method, washed by decantation with hot H_2O and dissolved in a known vol. of a warm mixt. of 0.5 *N* H_2SO_4 and 0.25 *N* (0.5%) H_2O_2 . The H_2O_2 is added from a buret until it is in slight excess. The acid is used according to the equation $\text{Cu}_2\text{O} + \text{H}_2\text{O}_2 + 2\text{H}_2\text{SO}_4 = 2\text{CuSO}_4 + 3\text{H}_2\text{O}$ and is detd. by back titration of the excess using 0.5 *N* NaHCO_3 soln. in 100 cc. of H_2O contg. 3 drops of methyl orange indicator. The end point is a permanent yellow-green color. The excess of acid is calcd. by use of the factor 1.020, and the amt. of acid consumed multiplied by the factor 0.015378 gives the amt. of Cu in the Cu_2O . The sugar soln. should not contain over 0.5% glucose and the H_2O_2 - H_2SO_4 mixt. should not be used if more than 30 days old. C. R. F.

Determination of maltose and glucose. W. BRAUN, B. BLEYER AND W. ELHARDT. *Chem. Hochschule München. Z. anal. Chem.* 76, 1-38(1929).—The reduction values of the purest obtainable glucose and maltose were detd. very carefully so that with the aid of the tables given in this paper it is possible to det. glucose and maltose when present singly or together. Several different procedures were studied critically. The original paper should be consulted for details. W. T. H.

Determination of sulfur in organic substances. IVAN MAREK. *Bull. soc. chim.* **43**, 1405-7(1928).—See *C. A.* **22**, 1933. E. J. C.

pH measurement with the glass electrode and vacuum tube potentiometer (ELDER, WRIGHT) **2**. The behavior of the Sb electrode in buffered and unbuffered solutions (LAVA, HEMEDS) **2**. Determining carbon dioxide in flue gases. HEINZ GRÜSS (to Siemens & Halske A.-G.). U. S. 1,701,181, Feb. 5. An app. is used comprising at least one testing wire surrounded by the flue gases and another wire lying in a comparison gas, connections between the wires for establishing a Wheatstone bridge, and a double coil instrument inserted in the diagonal branch of the bridge; the bridge is supplied with elec. current of such intensity that the wires have the same temps. and that these lie between 200° and 350°. Cf. *C. A.* **23**, 551.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIERER

The color of minerals. I. The absorption of red colored minerals in the visible part of the spectrum. O. WEIGEL AND G. HABICH. *Neues Jahrb. Min. Geol., Abt. A, Beil.-Bd.* **57**, 1-56(1928).—This paper comprises mainly phys. data, but analyses of almandine, pyrope and grossularite are given. J. F. SCHAIERER

Crystal forms of wolfsbergite. E. ERNST. Univ. Heidelberg. *Neues Jahrb. Min. Geol., Abt. A, Beil.-Bd.* **56**, 275-315(1927-8).—The identity of guejarite with chalcostibite (wolfsbergite) Cu₂S.Sb₂S₃, announced by Penfield and Frenzel in 1897 is confirmed by new crystallographic data. J. F. SCHAIERER

New mineral [berthonite] from Tunis. H. BUTTGENBACH. *Ann. soc. geol. Belg.* **46**, 212(1927).—Berthonite, d. 5.49, hardness 4-5, contains Pb 21.83, Cu 23.68, Sb 32.45%, corresponding with the formula 5PbS.9Cu₂S.7Sb₂S₃. B. C. A.

Minerals from new veins in Belgian Congo. H. BUTTGENBACH. *Mém. soc. roy. sci. Liège* [3], **14**, No. 4(1927).—Accounts are given of several minerals from veins of Cu ore in limestone near intrusive rocks recently discovered at several places along the tributaries of the Lubi River. Massive stromeyerite contains: Cu 20.45, Ag 60.00, S 15.65, Fe 0.26, insol. 2.56, sum 98.92%. Planchéite intermixed with shattuckite and chrysocolla gave: SiO₂ 41.24, CuO 50.67, CaO trace, H₂O 5.54, moisture 0.85, insol. 1.36, sum 99.66%. Crystals of willemite, barite, libethenite and volborthite are figured and described. B. C. A.

The minerals of the enargite group and their paragenetic relations in the copper ore deposits of Mancayan in Luzon, Philippine Islands. GEORG FREIBOLD. *Neues Jahrb. Min. Geol., Abt. A, Beil.-Bd.* **56**, 316-33(1927-8).—On the basis of x-ray data, the evidence for the existence of the mineral luzonite is very weak. It is suggested that the so-called luzonite is a mech. mixt. of enargite and famatinite. J. F. S.

Crystallography of aurichalcite, danburite, cerussite, etc. H. BUTTGENBACH. *Mém. soc. roy. sci. Liège* [3] **12**, No. 9(1924).—A review is given of the literature on the crystallography and optics of aurichalcite. A new crystal-form is noted on danburite from Switzerland. Twinned crystals of cerussite from Tunisia are figured and described. Crystallographic data are given for *m*-xylylhydrocotarnine, *o*-, *m*- and *p*-tolylhydrocotarnine, tin dibromodi-*p*-tolyl, tin tetratolyl (*o*-, *m*- and *p*-), tin tetra- α -naphthyl. B. C. A.

Fine structure of the feldspars. E. SCHIEBOLD. *Fortschr. Mineral. Kryst. Petrog.* **12**, 78-82(1927).—The monoclinic feldspars are basal-face-centered, the edges of the unit cell being parallel with the crystallographic axes *a*, *b* and *c*. Values of *a*₀, *b*₀ and *c*₀, resp., are as follows: adularia, 8.61, 13.07, 7.26; sanidine, 8.42, 12.92, 7.14; microcline, 8.44, 13.00, 7.21; hyalophane, 8.50, 12.92, 7.12; albite, 8.23, 13.00, 7.25; oligoclase, 8.16, 12.90, 7.13; labradorite, 8.23, 12.91, 7.16; anorthite, 8.185, 12.895, 7.09 A. U. The space-group for the monoclinic feldspars is C_{2h}, and for the triclinic, C₁. The effect of changes of compn. on the dimensions of the unit cell is considered. B. C. A.

Anorthoclase in caucasites. D. S. BELYANKIN. *Bull. acad. sci. Russ.* 1927, 1115-23.—B. classifies the anorthoclases with orthoclases and distinguishes the 4 series: K and Na anorthoclases, either with low or medium values of $2V$ or with high values of $2V$. It is suggested also that the anorthoclases with low or medium $2V$ be termed K sanidine (or simply sanidine) and Na sanidine, resp. K sanidine occurs widely in igneous rocks, principally in intruded materials and mostly in those of recent age. B. C. A.

Chemical composition of augite and biotite from tephritic lava and the Laacher trachyte. R. BRAUNS. *Min. Inst. Univ. Bonn. Neues Jahrb. Min. Geol., Abt. A, Beil.-Bd.* 57, 131-8(1928).—Analyses of augite and biotite are given. J. F. S.

Analcite. S. DI FRANCO. *Boll. soc. geol. Ital.* 45, 1(1926).—A specimen of analcite contained: H_2O 8.22, SiO_2 54.10, Al_2O_3 23.68, CaO 0.45, Na_2O 13.40, K_2O 0.34%, and had d 2.249. B. C. A.

Apophyllite. S. DI FRANCO. *Atti accad. Gioenia sc. Na. Catania* 15, No. 7 (1926).—A specimen of apophyllite contained: SiO_2 52.75, CaO 25.43, K_2O 4.73, Na_2O 0.43, H_2O 16.8% and had d_{15} 2.375. B. C. A.

Serpentine and chlorite. N. KURNAKOV AND V. CHERNIKH. *Mem. Soc. Russ. Min.* 55, 183-94(1926); cf. *C. A.* 22, 932.—The formula, $H_2Mg_3Si_2O_8$, fairly accurately expresses the compn. of many serpentines; if Al_2O_3 (up to 8.2%) is present, the chlorites are approached. The nature of the heating curves is discussed. With increase in the Al_2O_3 content the orthochlorites show conversion into corundophilite and amesite. B. C. A.

Rare earths of Japanese wolframites. MASATAKE KOSAKI. *Bull. Inst. Phys. chem. Research (Tokyo)* 7, 540 2(1928); *Abstracts* 1, 50.—Wolframites from: (1) Takatori, Hitachi province and (2) Akenoba, Tajima province were fully analyzed giving, resp.: WO_3 70.47, 77.12, MnO 10.55, 0.81, FeO 10.00, 17.52, Fe_2O_3 2.65, 1.61, Al_2O_3 5.71, 2.02, SiO_2 0.89, 0.18, SnO_2 0.09, 0.34, P_2O_5 0.33, —, rare earths 0.04, 0.10%. The mineral from Akenobe is therefore the ferberite variety of wolframite. The spectral analysis shows that the Takatori specimen contains Sc, Yt and Ho, the lines of the latter being predominant. It agrees thus with wolframite from Zinnwald, Bohemia, in contg. Sc as a minor constituent. ALBERT L. HENNE

Recent advances in science: Geology. G. W. TYRRELL. *Univ. Glasgow. Science Progress* 23, 409-17(1929).—A review of recent work on volcanology and the igneous rocks. JOSEPH S. HEPBURN

Transition deposits of the intrusive-magmatic type. I. Tin, tungsten and molybdenum. ARNOLD CISSARZ. *Neues Jahrb. Min. Geol., Abt. A, Beil.-Bd.* 56, 99-274 (1927-8). A detailed geological description of the natural deposits is given. Diagrams showing the chem. compn. of Sn-bearing rocks are included. Practically all Sn, W and Mo deposits are of hydrothermal origin. A very complete bibliography is given, by localities. J. F. SCHAIER

Genesis of the Silver Hill tin deposits. ALFRED L. ANDERSON. *J. Geology* 36, 646-64(1928).—Southeast of Spokane, Wash., are cassiterite-bearing pegmatites carrying both andalusite and sillimanite. These dikes are differentiation products from a magma which has produced submagmas as basic as kersantite and as acid as aplite and quartz veins. The andalusite was pptd. first, followed by cassiterite. Hydrothermal solns reacted with the earlier-formed minerals, producing orthoclase with intergrown sillimanite needles. Wolframite, scheelite, galena and tourmaline also occur in small amts in the pegmatites and associated quartz veins, illustrating a common origin for both. W. F. HUNT

The refractory earths of Novarese. G. MILANI. *Corriere ceram.* 9, 427, 429 (1928).—The av. analysis of some silica earths from Novarese, Italy, is given. "Rosa" is a pulverulent material contg. SiO_2 78, Al_2O_3 12, Fe_2O_3 2, and alkali 2%. "Santuario" is whitish and contains less Fe. The analysis of "Moscotti," which is a yellowish, plastic material, shows SiO_2 66, Al_2O_3 18, Fe_2O_3 1.5%, and traces of CaO and MgO . "Marta" is a very friable earth of blood-red color and contains SiO_2 65, Al_2O_3 16, Fe 2.25, MgO 4%, and traces of CaO ; the min. loss on ignition is 7%. G. SCHWOCH

Dikes belonging to the Alnø formation in the cuttings of the East Coast Railway. HARRY VON ECKERMANN. *Geol. För. Förh.* 50, 381-412(1928).—E. studied the dikes cutting the granites previously described (*C. A.* 23, 1085) and made 8 new analyses, which are given. A mica-carbonate dike at Bergeforsen contained dolomite, sodabiotite, barite, ilmenite, pyrrhotite and a blue unknown mineral. A feldspar-carbonate dike at Bergeforsen contained K feldspar, magnesite, dolomite, magnetite and goethite. A hamrongitic alkaline porphyrite dike at Bergeforsen contained larger and smaller well defined white feldspar phenocrysts within a grayish green ground mass.

A beforsitic biotite-chlorite-carbonate dike at Bergforsen contained light brown biotite, green borders of chlorite, a carbonate, orthoclase, quartz, olivine, serpentine, and an unknown blue mineral. E. selected 4 of the several dikes at Stavre as representative. (1) An alnöite dike rich in carbonates, contg. calcite 37.0, biotite 29.2, hornblende 15.6, augite 14.0, perovskite and ores 3.8, barite 0.4, sum 100.0%. The relation of CaO to MgO and FeO is markedly different from that of older analyses of alnöites. (2) A beforsitic alnöite dike was mostly made up of biotite, chlorite, and calcite. (3) A Sr-bearing aragonitic beforsite dike contained biotite, apatite, magnetite, perovskite, pyrite, fluorite, barite, chalcedonite, and carbonates of Ca, Mg, and Sr (SrO 0.74%). (4) A stavrite dike consisted mainly of a mass of amphibole needles with biotite and some chlorite, calcite, quartz and ilmenite in the interstices. A calcitic beforsite dike at Söråker consisted of fluidally elongated almost banded parts of typical beforsite with mica-phenocrysts alternating with more carbonatic rock: calcite 61.8, biotite 28.4, apatite 6.1, magnetite 1.6, pyrite 1.4, perovskite 0.7, sum 100.0%. E. discusses the differentiation of the dikes at some length and points out new lines of attack on the problem of mineral paragenesis. The relative *cfm* is evidently of very great importance in the differentiations of the dikes. This is illustrated by several examples drawn from the minerals studied. W. SEGERBLUM

Geology and paleontology of South America. XXIX. Eruptive rocks and their contact rocks from the Cordillera of Bolivia and Peru. RICHARD VIELMEYER. Min. Inst., Univ. Bonn. *Neues Jahrb. Min. Geol., Abt. A, Beil.-Bd. 56*, 23-68(1927-8).—An analysis of granite is included. J. F. SCHAIRER

Quartz in porphyritic rocks. FRANZ ANGEL. Min.-petr. Inst. Graz. *Neues Jahrb. Min. Geol., Abt. A, Beil.-Bd. 56*, 1-22(1927-8).—Quartz, either as phenocrysts in the original magma or as xenoliths of sandstone, does not come into equil. with the magma. Resorption aureoles in porphyritic rocks from Rumania and Steiermark are described. J. F. SCHAIRER

The chemical composition of the basalt lavas of the Laacher See region. R. BRAUNS. Min. Inst. Univ. Bonn. *Neues Jahrb. Min. Geol., Abt. A, Beil.-Bd. 56*, 468-98(1927-8).—Analyses are given of loess, basaltic lava, scoriaceous lava, leucite-nephelite-basalt, leucite basalt, and hauynite-rich leucitite. J. F. SCHAIRER

Olivine diabase from Braunlage in the Harz. K. SCHLOSSMACHER AND K. HEYKES. *Neues Jahrb. Min. Geol., Abt. A, Beil.-Bd. 57*, 163-72(1928).—Analysis of the olivine-diabase is given, as well as that of ankerite grains found in the rock. J. F. S

Magmatic differentiation in the Gleinalm region, Steiermark. FRANZ ANGEL. Min.-petr. Institute, Graz. *Neues Jahrb. Min. Geol., Abt. A, Beil.-Bd. 56*, 423-67(1927-8).—The complex chem. and mineralogical changes during magmatic differentiation producing the various rocks of the region are described. J. F. SCHAIRER

Notes on the precipitation of calcium carbonate. R. C. EMMONS. *J. Geology* 36, 735-42(1928).—A series of expts. covering a period of 2-8 months to det. the factors controlling pptn. Conclusions: (1) contact of air with water satd. with $\text{Ca}(\text{HCO}_3)_2$ ppts. CaCO_3 by removing CO_2 from soln.; (2) agitation of soln. has the same effect; (3) reduction of pressure has only a slight effect; (4) in quiet water CaCO_3 ppts as a fine powder while in circulating water the CaCO_3 is coarsely cryst. W. F. H

Area and origin of meteoric glasses (tektites). G. LINCK. Min. Geol. Inst. Jena. *Neues Jahrb. Min. Geol., Abt. A, Beil.-Bd. 57*, 223-36(1928).—Tektites show a range in sp. gr. of 2.337-2.48 and in *n* of 1.486-1.5097. The av. compn. is near that of a fused clay; they are, however, fused sedimentary rocks. Viscous glasses were probably fused under pressure and the surface sculpturing was produced at this time. It is suggested that tektites are volcanic bombs shot from the moon during the Pleistocene period. J. F. SCHAIRER

Fulgurites from the Miocene glass sands of Guteborn near Ruhland. WALTHER FISCHER. Min. Geol. Museum, Dresden. *Neues Jahrb. Min. Geol., Abt. A, Beil.-Bd. 56*, 69-98(1927-8).—Analyses of fulgurites, and the quartz sand and clay deposit in which they occur, are given. The fulgurites found in the sand are nearly pure silica glass (lechatelierite). J. F. SCHAIRER

The residue in silica determination. P. J. BEGER. *Neues Jahrb. Min. Geol., Abt. A, Beil.-Bd. 57*, 237-48(1928).—Analyses of lamprophyre and a coarse grained schlieren were made, and the residue from the SiO_2 detn. was tested and compared with the results of Arousseau on an andesite from California. B. decides that the residue is usually high in rocks rich in R_2O_3 . J. F. SCHAIRER

Research within an industry creates the demand—and supplies it. EVERETT PARTRIDGE. *Ind. Eng. Chem.* 21, 37-40(1929).—The function of the research department of the Vanadium Corporation of America in creating a demand for V and in supplying necessary material to manufacturers is shown. V used in the United States in 1906 was about 750 lbs., in 1924 about 1,000,000 lbs., and the calcd. demand 1930 is about 1,800,000 lbs., with an additional 800,000 lbs. to be used in other countries. Over 90% of the world's supply is under American industrial control, though the ore comes chiefly from Peru and South Africa; only about 16% of occurs as mineral deposits within the United States. The recovery from V-steel and other alloys by the acid open-hearth furnace is increasing rapidly. Types of research problems are given, including the development of manufacturing processes for Corporation itself and the utilization of products made by it. Among the latest projects are the prepn. of catalysts, medicinals, and rare chemicals of c. p. and technical grades. Coöperation with consumers of its products, with research as a consulting vice, has given valuable results.

European factory methods and equipment in the manufacture of metals. DAVID EVINGEN. *Mining and Met.* 9, 483-6(1928).—In an English plant Cu wire bars cast in vertical molds are carried on conveyors to the hot rolling mill where they are rolled without being allowed to cool, thus conserving heat and saving an operation. Europeans have adopted the use of repeaters in rod mills more than the Americans have. In Germany, Austria and Switzerland hot rolling of brass is replacing cold rolling. Germany excels in the machine tool field. Throughout continental Europe a new German type of automatic screw machine is replacing a popular American type rapidly. The same type has made its appearance in this country.

The speed of reduction of iron ores in flowing gases. HANS H. MEYER. *Mitt. Kaiser-Wilhelm Inst. Eisenforsch. Düsseldorf* 10, 107-16(1928).—At 650° the ores reduced in H begin to sinter, and H diffuses less readily to the center of the kernels. As a result the speed of reduction falls rather sharply. At 900° the speed is again accelerated, since H diffuses more rapidly into the γ -Fe. In CO, sintering is effectually

prevented by the sepn. of C. The speed of reduction, however, is slower than with H so long as there is no sintering. For technical purposes a mixt. of CO and H is very effective, because of the reactivity of the H and the prevention of sintering by the CO. Magnesite reduces chiefly on the surface, and the higher the temp., the greater must the degree of reduction be before C is set free. The presence of H promotes C formation. With minette (Fe silicate) the phenomena are the same, but because of its greater porosity the reduction is more rapid. Likewise the sepn. of C in the interior of the kernel tends to break it up. Above 1000° silicates are formed which close up the pores and retard the reaction. Where no sintering occurs the speed of reduction is about 4 times greater with H, and in both cases the speed is proportional to the surface of the ore and the concn. of the gas, the reaction velocity const. being d/D , where d is the diffusion coeff. and D is the thickness of the adsorbed gas layer. The temp. coeff. of the speed of reaction is consequently quite small. In H-CO mixts. the CO does not appear to reduce directly, but converts the water formed into H and CO₂.

HANS C. DUUS

Colloid slime, finely ground ore, and hydrometallurgical treatment. JOHN GROSS AND S. R. ZIMMERLEY. *Eng. Mining J.* 126, 943(1928).—Some Au is lost in cyaniding by adsorption on the large amt. of particle surface formed by fine grinding. In milled Au ore the total surface on +200 mesh material is small in comparison with that on -200 mesh material. The Bureau of Mines is extending screen sizes and sepg. products down to av. size of 1 micron by elutriation. JOHN DIXON. *Ibid* 943-4.—At Kirkland Lake, Ont., 20-30 ϕ . in dissolved Au was lost with the tailing because of imperfect washing. Detn. of this loss by assaying the soln. decanted from the daily tailing sample and detg. the % moisture in the pulp gave results about 20 ϕ . too low. The discrepancy is explained in part by adsorption of Au on particle surfaces and in part by absorption of soln. in colloid slime; the latter was found to be much the larger factor. A suction filter introduced in the washing circuit broke down the absorption and greatly reduced the dissolved-Au loss. Cyanide and lime consumption have, likewise, been reduced.

A. BURTS

Lime scale as a concentrate. R. F. HEAD U. S. Bur. of Mines and Univ. of Utah. *Mining and Met.* 9, 455-7(1928).—A lime scale contg. 95.32 oz. Au and 35.88 oz. Ag formed in Callow flotation cells at Spring Garden, Cal. Microscopic studies on thin sections showed the mass of scale to be an aggregate of individual calcite crystals which contained quartz grains together with particles of Au, Ag, sulfides and black carbonaceous material. The Au and Ag particles apparently were floated by the coating of carbon, which was of natural origin, and not due to flotation reagents. Since carbon-coated Ag and Au are fairly common the lime scales may prove an important source of revenue in many flotation plants.

E. H

Contributions to the knowledge of blast-furnace processes. GEORGE EICHENBERG AND PAUL OBERHOFFER. *Arch. Eisenhüttenwesen* 1, 613-28(1928).—Investigations were made on: (I) the gas compn., pressure and temp. relation in a crude Fe-foundry blast furnace at various depths and the entire height, during 24 hrs.; (II) the position and expansion of the reduction zones during the conversion of the furnace from crude foundry Fe to crude steel Fe by observations on the rising gas streams and by the temps. at the various levels; (III) a comparison of the reduction relations in a blast furnace operating with gray and white Fe. No better results (close to those of previous investigators) can be obtained by the methods used, and new ones should be devised. There is a decrease in the total amt. of gas from the tuyère to the throat, and from the sides towards the center of the furnace. An absorption of the C in the gas layers at 900-1000° takes place, as indicated by its disappearance from the gases in this field. It is shown that the coke consumption of the lower portion of the furnace detcs that of the entire furnace, the excess heat produced here being sufficient to cover the needs of the top portions. The thermal efficiency of the lower portion is considerably greater than that of the top. For the furnace used, the thermal efficiency cannot be increased in using the same type of charge and producing the same sort of Fe. The zones of indirect reduction are shifted considerably after the charged scrap has reached the C-pockets during passage. In the rising gas stream, indirect reduction occurs principally between 400° and 650°, direct reduction beginning at about 900°. There is considerable increase in the degree of the indirect reduction with decreasing gas temps. for crude steel Fe.

The hydrogen content of blast-furnace gas. BERNHARD OSANN. *Bergakademie Clausthal. Arch. Eisenhüttenwesen* 1, 673-5(1928).—In investigations to det. the relation between the H_2O in the charge and blast, and the H_2 content of the gases in a 550-ton furnace gas samples were taken every 10 mins. for 17 days. The values of the H_2 content as calcd. by O. (*Lehrbuch d. Eisenhüttenkunde*, vol. 1 (Leipzig, W. Englemann, 1923) pp. 507-8, 650; cf. C. A. 18, 1107) av. only 7% higher than those found. By artificially adding H_2O , 50 l./min., to the blast for 30, 12 and 5 mins. the H_2 in the throat gases is trebled. Between $1\frac{1}{2}$ and $2\frac{1}{2}$ of the H_2O introduced is decomposed; this is explained partly by the mass law and partly by the resultant cooling. The H_2 in the gases is not related to the moisture content of the coke and ore, nor to the H_2O of hydration. The H_2 liberated in the lower furnace is not used in the reduction of the Fe-O compds.

Is the heating chamber of a Siemens-Martin furnace a black body for the optical measurement of temperature? HERMANN SCHMIDT AND WILHELM LIESEGANG. *Arch. Eisenhüttenwesen* 1, 677-85(1928).—Measurements in the visible field of the spectrum with a Wanner optical pyrometer through the peep hole of the withdrawing head of a basic 50-ton furnace show that the upper portion of the Siemens-Martin furnace is not to be regarded as a completely black body. The furnace shows free brick radiation in a reduced amt. The decrease in dispersion following rapidly on starting the furnace must be ascribed to the progressive equalizing of the temps., and the increased blackening of the brick surface by lime, MnO_2 and Fe_2O_3 . With blue light, the highest temp. obtained for the heating chamber varies from 1700° to 1730° . It is recommended to use blue rather than red light in the pyrometer. The dispersion of $20-30^\circ$ corresponded with the blue light at 1725° to a "furnace absorptive power" of 0.85-0.90 in red light. With a Holborn-Kurhlbaum pyrometer it is detd. that for $\lambda = 0.65\mu$, the av. absorptive power is 0.55 at 1300° . The temp. dispersion of free-radiating silica brick averages 53° , at about 1500° . Photographs of the crown and rear wall of the furnace interior, during operation, agree with this. The absorptive power increases with the temp. and with decreasing wave length. The most important optical pyrometric detns. of temps. in the Siemens-Martin furnace of earlier investigators are tabulated.

J. BALOZIAN

Investigations on the addition of carburizing agents to a Siemens-Martin furnace heated by mixed gas. FRIEDRICH STEIN. *Arch. Eisenhüttenwesen* 1, 629-38(1928).—An investigation was made of the influence of firing a stationary (usual construction), a 60-ton Maerz, a 40-ton (usual construction) and a 70-ton tilting furnace, with mixed gas alone and in admixt. with tar or tar oil, or equal parts of both. The furnaces used in the Siemens-Martin Works II Ruhrort-Meiderich Smelter, and the oil burner are briefly described. Carburizing mixed gas with tar or tar oil gives a normal fusion without harmful overheating of the furnace. No unburned gas could be detd., the furnace lasting longer than if generator gas is used alone. Only a small change in the furnace process takes place when the amt. of added carburizer is varied. Operation is simple and requires little attention when the mixt. of tar-tar oil is used, the large excess of throat gases being utilized. The addn. of carburizing agents is of distinct advantage in starting the furnace. A disadvantage is fluctuation in the throat and coke-gas supply.

J. BALOZIAN

Spectral-pyrometric measurements on a Siemens-Martin hearth. HERMANN SCHMIDT AND WILHELM LIESEGANG. *Mitt. Kaiser-Wilhelm Inst. Eisenforsch. Düsseldorf* 10, 71 89(1928).—Spectral-pyrometric measurements made during 8 melts in a period of 2 months showed that a Siemens-Martin hearth cannot be regarded as a wholly black body. This is shown by the fact that the materials of which it is built can readily be distinguished from the melt, and by the further fact that the temps. as measured by blue and red light averaged 53° higher for the blue. The highest temp. measured with blue light was 1720° , which checked well with the softening limit of the stones and with the color of the melt. Consequently blue light is to be

preferred for measurements. The mathematical aspects of the Siemens-Martin hearth as a black body are also considered, and a micropyrometer is described.

HANS C. DUUS

Gas-fired car-bottom furnaces used for annealed steel castings. WM. P. HAND. *Fuels & Furnaces* 6, 1751-2(1928).—A description of the construction and operation of an automatically controlled gas-fired car bottom furnace installation. H. C. P.

High-speed steel—crucible versus electric furnace products. EDWIN A. BROPHY. Braeburn Alloy Steel Corporation. *Chem. Eng. Mining Review* 20, 305-7(1928).—The product from the elec. furnace is considered superior because of better control of temp., greater homogeneity of the product, mathematical precision of the analysis, const. repetition of specifications, and better abs. control of the slag—oxidizing, neutral and reducing.

HANS C. DUUS

Use of pulverized fuel in metallurgical furnaces. GEORGE E. K. BLYTHE. *Fuels and Furnaces* 6, 1661-6(1928); cf. C. A. 22, 3380.—Four stages occur in the combustion of pulverized fuel (1) heating and drying, (2) gasification of the volatile matter and coking the C, (3) combustion of gases and (4) combustion of the coke particles. The distr. stage starts at about 400°F. Gases and volatile vapors are given off until combustion starts. The rapidity with which free C particles combine with O depends largely on the speed of mixing with heated air. Unless the products of combustion of the volatile gases are swept away, the coke remains surrounded by inert gases. Each particle must come into contact with many thousand times its own vol. of air to burn completely. Violent mixing is therefore essential. Operating records show economies resulting from the use of pulverized coal in firing annealing furnaces, tunnel and batch furnaces, heavy and light forge furnaces, puddling, malleable-iron, melting, Cu refining and Ni reverberatory furnaces. B. discusses pulverizers, driers and transporting systems.

E. H.

The reaction between magnetite and ferrous sulfide. F. S. WARTMAN AND G. L. OLDRIGHT. Bur. of Mines, *Repts. of Investigations*, No 2901, 14 pp.(1928).—This investigation was undertaken (1) to explain the apparently inconsistent behavior of Fe_3O_4 in the Cu reverberatory furnace, and (2) to det. more exactly the rate of reaction of Fe_3O_4 and FeS in this furnace. Previous work on this reaction is briefly reviewed. Mixts. of Fe_3O_4 and FeS were heated in a current of N at predetd. temps. The app. was set up in the following order: a source of N, a flow meter, app. to purify the N, a reaction tube enclosing the boat contg. the $\text{FeS-Fe}_3\text{O}_4$ mixt., a furnace for heating the reaction tube, and an absorption app. for collecting the gaseous products of the reaction. The overall result of the reduction of Fe_3O_4 by FeS in the temp. range 1000° to 1300° can be represented by three equations: (1) $\text{FeS} + 3\text{Fe}_3\text{O}_4 = \text{SO}_2 + 10\text{FeO}$, (2) $\text{FeS} + \text{Fe}_3\text{O}_4 = \text{S} + 4\text{FeO}$; (3) $\text{FeS} + 4\text{Fe}_3\text{O}_4 = \text{SO}_2 + 13\text{FeO}$. With the mixts. tried most of the reduction proceeded according to the first reaction. Increasing the proportion of sulfide increases the rate and also to some extent the importance of the other reactions. Increase of temp. increases the rate of reduction very markedly. Increase of partial pressure over the melt, of the gases formed by the reaction, greatly decreases the rate of reduction. Fe_3O_4 and FeS will be found in stable association in roaster calcines because the temps. found in roasters are below those at which Fe_3O_4 and FeS react to an appreciable extent. Fe_3O_4 and FeS in contact on the surfaces of the charge heaps in the reverberatory smelting zone will react easily because the temp. is high enough and the gases from the burners will dilute and carry away the gaseous products of the reaction as fast as they are evolved. Fe_3O_4 crystals at the bottom of the furnace will not be reduced because the head of overlying mat and slag exceeds the pressure at which the reducing reaction will proceed. J. W. W. S.

The precipitation of copper from mine waters at Britannia Mines. B. C. F. EBBUTT AND W. E. SELNES. *Can. Min. Met. Bull.* No. 199, 1290-1309(1928).—Description is given of expts. beginning in 1924 and development of the com. plant that has resulted. Rain falling on the glory-holed and caved area of the worked-out Fairview mine seeps slowly through crevices and glory-holes to come in contact with ore. The upper levels are partly oxidized and offer excellent conditions for percolation of the water and taking up of Cu, while on the lower levels very little soln. occurs. Due to variation of rainfall with the season, the Cu content of the mine waters varies from 0.6 to 1.2 g. per l., and conditions in the plant operation vary accordingly. To recover the Cu the water is passed through 2 or 3 launders in series, each launder being 10 ft. long and 5 by 5 ft. in section, built entirely of wood. The best precipitant is scrap tinplate obtained from canneries; it is placed on grids in the launders and air at 70

lb. pressure is introduced beneath it through rubber hose. This air agitation was found to double the recovery of Cu as well as eliminate the labor of stirring the tinplate. Total recovery averages over 90% of the Cu content of the water. The cement Cu is 60 to 70% Cu. Over 50,000 lbs. of Cu a month is being recovered at a cost of 7.2¢ per lb., using 1.6 lb. of tinplate per lb. of Cu. Operation is described and the chemistry of soln. and pptn. discussed.

A. BUTTS

Gold leaf—old and new. IVOR GRIFFITH. *Bull. Wagner Free Inst. Sci. Philadelphia* 3, 59-62(1928).—The manuf. of gold leaf is described. In 3 hand-beaten samples of American manuf., the sheets ranged from $3\frac{7}{8} \times 3\frac{3}{8}$ to $3\frac{29}{32} \times 5\frac{5}{32}$ inches in area, and from 0.01662 to 0.01887 g. in wt. The wt. per sq. inch ranged between 0.00093 and 0.00144 g. The Au content (in parts per 1000) ranged between 759 and 791, the Ag content between 190 and 218, and the content of base metals between 19 and 25. They had a fibrous structure. A sample of foreign manuf. had a crystalline structure, and probably was deposited electrolytically; its sheets varied in area, weighed 0.001199 g. per sq. inch, and contained 834 parts Au, 74 parts Ag and 92 parts base metals.

The importance of the equilibrium diagram in metallurgy. W. ROSENHAIN. *National Phys. Lab. J. Inst. Metals* 39, 27-52(1928).—See *C. A.* 22, 2915.

ROBERT F. MEHL

Methods of diagram evaluation. K. HERRMANN. *Z. Metallkunde* 20, 359-62(1928).—The general process of evaluation is described for x-ray diagrams such as are obtained by the *rotating crystal*, *Debye-Scherrer* or *Laue* methods. The geometric and mathematical relations are discussed, and a short graphic method is described.

H. STOERTZ

Thermoelectric power in cold-worked metals. W. F. BRANDSMA. *Z. Physik* 48, 703-5(1928).—The thermoelec. power appearing between cold-worked and recrystd. cathodes was found to be reproducible, providing the preliminary treatment was identical. The effect increases with the degree of working. On heating the cold-worked wire to a definite temp. the effect was found to decrease slowly to a value characteristic of the temp.

B. C. A.

Determination of the degree of tarnishing of a metallic surface by its reflective power. G. ANDO. *Mem. Coll. Sci. Kyoto* 11A, 85-93(1928).—The reflective power of a metal surface is detd. directly after polishing and also after keeping the polished surface for a given time in an atm. contg. known amts. of moisture and CO₂. The ratio of the two reflective powers is a measure of the degree of tarnishing. The method has been applied to several alloys.

B. C. A.

Significance of mechanical twin formation for plasticity and hardness. E. SCHMID. *Z. Metallkunde* 20, 421-5(1928).—The mechanism of crystal deformation is discussed, with particular reference to twin formation. If χ and λ are the angles between the direction of strain and the slip plane or direction of mech. twin formation, the following expression is obtained for elongation (d): $d = l_1/l_0 = \sqrt{1 + 2s \sin \chi \cos \lambda + s^2 \sin^2 \lambda}$, where s is the magnitude of displacement and is generally small. The effect of twin formation is to convert a translation plane located in a direction unfavorable to any extended deformation into a plane in a position very favorable to large deformation in translation. Expts. with Zn and Cd show that an increase in hardness at the point of translation is brought about by twin formation.

H. STOERTZ

Effect of the velocity of test on notch brittleness. JAMES G. DOCHERTY. *Engineering* 126, 597-600(1928).—In view of the conflicting data found in the literature on the relation between slow-bend and impact tests D. carried out a number of bend tests. Standard Izod notched specimens of mild steel (0.25% C), Ni-steel (0.38% C, 3.8% Ni) and naval brass (61% Cu, 37.4% Zn, 1.4% Sn) were used. The speed of the striker was varied from 50 to 0.05 in./min. The results obtained were recorded graphically in diagrams showing the work done as a function of distance traveled by the striker. The tests indicate that increase of speed is connected with an increase in energy absorbed. For mild steel and naval brass the increase seems to be continuous up to the speed of the Izod test. In the case of Ni-steel the energy absorption likewise increases as the speed of the striker is increased but the standard Izod values (at striker speeds of 3500 and 7000 in./min.) are considerably below those obtained for low speeds. This may be a sign that there is a critical speed above which the "cracking" effect predominates with consequent diminution of energy absorbed.

H. S. VAN KLOOSTER

The loading of hot plate rolls. L. WEISS. *Z. Metallkunde* 20, 389-93(1928).—The proper loading of rolls is studied. If M_b is the bending moment for the roll pres-

sure P , L_1 the supported length of the roll, and b the width of the strip being rolled, $M_b = P/2(L_1/2 - b/4)$. If W is the resistance moment in cc., then $M_b = k_b W$ and $P = 2k_b W/(L_1/2 - b/4)$. If σ is the flow pressure in kg./sq. cm., the roll pressure P also $= \sigma bc$, and since $c = \sqrt{2ri - i^2} \cong \sqrt{2ri}$, in which i is half the decrease in thickness of the plate being rolled and r the radius of the rolls, then it follows that $P = \sigma b \sqrt{2ri}$, and $2i = (P/b\sigma)^2/r$. A table is included in which $2i$ is given for various values of k_b and roll widths at 600°, 750° and 900°, for Cu, Al and cast Fe rolls. Curves are also shown. In general $i_{\max.} \cong r/25$. With Al rolls, lighter loads are generally used and the $2i$ value falls quickly with decreasing temp. Thus for Al rolls (850 × 3300) with $k_b = 300$ kg./sq. cm., $b = 360$, $2i = 1.25$ at 500°, 0.23 at 400° and 0.092 at 300°. With the same size Cu roll under the same conditions, $2i = 0.312$ at 900°, 0.138 at 750° and 0.046 at 600°. The life of the rolls can be calcd. with the formula $L_s = 2S.60 ny$, in which L_s is the no. of times the load has been applied, S the no. of hrs. of operation, y the no. of mins. per hr. the rolls are under pressure, and n the r.p.m. of the rolls. The highest value obtained with cast Fe rolls for L_s is 1,800,000. H. S.

Recent investigations of welds by means of x-rays. A. HERR. *Z. Ver. deut. Ing.* 72, 1671-6(1928).—Gross imperfections in the macrostructure of welds can, of course, be detected by radiographic methods using either a fluorescent screen or a photographic film. An explanation of the technic used and some specific examples are given. Tables are presented indicating the writer's experience of the necessary voltage and exposure times to secure satisfactory radiographs with different thicknesses of metal. These range from 100 kv. and one min. to 210 kv. and 240 mins. in the case of electrically welded iron of one and 10 cm. thickness, resp.; and from 120 kv. and one min. to 220 kv. and 240 mins. for gas-welded copper of 0.5 and 6.5 cm. thickness, resp. The indication of the fine structure of different parts of the metal as shown by Laue diffraction diagrams is of interest and will probably be of increasing importance as the interpretation of them becomes more definitely based on experience. At present, considerable difference is shown between diagrams, but the significance of these differences is not always clear. A. W. KENNEY

Cast-iron diagram of Maurer with varying rates of cooling. E. MAURER AND P. HOLTZHAUSEN. *Stahl u. Eisen* 47, 1805-12, 1977-84(1927).—A series of cast irons contg. 2.4-3.8% C, 0.8-1.0% Mn, 0.3% P, 0.1% S and varying quantities of Si were cast in chill molds and in sand molds heated at 250° and at 450° and, from an examn. of the microstructure of the castings, the Maurer equil. diagrams for cast iron under the different casting conditions have been constructed (cf. *C. A.* 18, 3346). For chill-cast specimens the boundary of the pearlite field is displaced towards the right, the line meeting the axis of C content (1% C) at 2.7% Si instead of at 2.5% Si; at its upper end this line bends towards the right with more than 3.1% C. For specimens cast into hot molds (450°), the boundaries of the pearlite field are displaced to the left, cutting the axis at 0.5% Si less than in the Maurer diagram, whereas for specimens cast into molds at 250° the Maurer diagram holds good. The rates of cooling of the castings in sand molds preheated at 250° and at 450° correspond with the rates of cooling of cylinders of 75 and 90 mm., resp., under foundry conditions. From the results obtained with these, therefore, the diagram for castings having walls between 10 and 90 mm. thick has been constructed. The presence of graphite eutectic together with ordinary graphite in both sand and chill castings and the increasing coarseness of the constituents with slower rate of cooling show that the ordinary form of graphite is obtained by a secondary action. The bending strength and hardness of cast iron are reproduced in the form of tables, graphs and space-moldel diagrams. B C A

Relation between the temperature of beginning crystallization and the foundry work. SEIKO HORIKIRI. *Inst. Osaka Ind. Research. Tetsu-to Ko (Iron and Steel)*, 14, 478-93, 549-67(1928).—H. took cooling curves of different kinds of cast Fe under different temps. of melt and the time of heating to det. the temp. of beginning crystn. and the eutectic temp., the comparative study of the structure being made at the same time. H. also classified the compn. of good cast Fe of low-C and high-Si content, examd. the cases of waste product resulting from the lowering of the casting temp., studied the relation between the temp. of beginning crystn. and mech. properties, and recognized that the casting should be made at a temp. which is, at least, 70-100° higher than the temp. of beginning crystn. H. also examd. the relation between the initial C-Si content of iron and the dendritic structure which is undesirable in the production of low-C castings. Although there is some range of compn. for which the wet mold may be used, for cast Fe contg. less than 2.7% C, no perfect casting can be obtained without a dry mold. H. then studied as a cheap means of obtaining low-

carbon castings the production of semi-steel by cupola-melting and showed that with the addn. of mild steel, a rapid solution of C in the melted zone is necessary for limiting the C content of the product, and inferred that the high Si content is favorable for the purpose. Thus, the casting is very easy with 2.0–3.5% Si, a suitable compn. being found for cylinder liner, piston and other high-class castings for engines. K. SOMEYA

Phosphorus and arsenic in steel and the substitution theory. A. E. CAMERON. *Trans. Can. Inst. Mining and Met.* 30, 858–68(1927).—The solid soly. of P and of C in γ -iron is about 1.7%, and the effects of the two elements on the mech. properties of Fe are approx. the same. C, however, increases the tensile strength owing to the insoly. of the carbide in α -iron and its sepn. on cooling together with the resistance to slip afforded by the finely-cryst. state of the eutectoid, whereas P can cause hardening only by producing distortion in the lattice of α -Fe. This distortion of the body-centered lattice of α -Fe produces the well-known cold-shortness of phosphoretic steels. Most steels contain As up to about 0.1%, but as the solid soly. of As in Fe is 6.8% the hardening and, therefore, the embrittling effect of As on steel is much less marked than that of P. An embrittling effect may, however, be caused by segregation of the As due to the presence of C in solid-soln.-producing areas in which the As content is very much higher than the av. The metal in these areas would then have a lower m. p. than the remainder, and during heat treatment may be in semi-plastic state, thus causing serious weakness and possibly breakdown during forging. B. C. A.

Impact resistance of steels at low temperatures. J. F. MORRISON AND A. E. CAMERON. *Trans. Can. Inst. Mining and Met.* 30, 839–57(1927).—The impact resistance of hypoeutectoid steels is decreased by exposure to low temps. At -30° the impact resistance of a normalized steel contg. 0.1% C is about one-tenth that of the same steel at 20° , while a normalized steel with 0.34% C has an impact strength at 20° 3 times as great as at -30° . The same steels in the quenched and fully tempered condition have an impact strength at -30° which is only slightly lower than that at 20° . For structural purposes in cities where a low winter temp. is experienced, the best resistance to shock is obtained by quenching from 900° followed by tempering at 610° . B. C. A.

Decarburization of high-carbon steel in "reducing" atmospheres. J. J. CURRAN AND J. H. G. WILLIAMS. *Trans. Am. Soc. Steel Treating* 14, 809–24(1928).—Carbonaceous packing mixts. may be either carburizing or decarburizing in their action, depending upon the activating material used in the mixt. and on the temp. of heat treatment. W. A. MUDGE

Some properties of quenched steels. KANZI TAMARU. *Bull. Inst. Phys. Chem. Research* (Tokyo) 7, 1028–34(1928); *Abstracts* 1, 99–100.—The magnetization of cementite in different forms is measured. The magnitude of the A_0 transformation of the pearlite cementite is larger than that of the globular cementite. Steel contg. 0.9% C has been quenched in H_2O and tempered at 392° for various times. If the time of tempering is short, the sepd. cementite is fine; its size grows with the time of tempering. The A_0 transformation is large when the cementite particle is fine, and becomes small when the latter grows. When a quenched high-C steel is tempered at a gradually increasing temp., two maxima of magnetization are observable at 120° and 300 – 350° . Both are supposed to be the same phenomenon, and correspond to the decomposition of α -martensite and the growth of minute cementite particles: the former results in the formation of ferrite and cementite and hence increases magnetization. The growth of cementite particles decreases magnetization. Steels containing 0.9% C have been quenched and tempered, the temp. and time of tempering being varied. The tempering effect is complete in 15 minutes at a temp. higher than 200° . Quenched steel contracts up to 200° , then expands to 260° and again contracts above 260° . The first contraction corresponds to the decomposition of the α - to β -martensite; the expansion corresponds to the decompn. of austenite to β - through α -martensite; the last contraction corresponds to the transformation of β -martensite to troostite. ALBERT L. HENNE

A new development in corrosion-resisting steel. F. R. PALMER. *Trans. Am. Soc. Steel Treating* 14, 877–88(1928); cf. C. A. 22, 1939.—The addn. of 0.40% ZrS_2 to high-Cr stainless Fe greatly improves machining and grinding properties and serves to reduce the tendency toward galling, scratching and seizing. A slight loss of toughness and tensile properties results. ZrS_2 tends to prevent air hardening and raises the temp. necessary for hardening. W. A. MUDGE

Progress in alloy steels during 1928. S. J. HEWITT. *Ind. Chemist* 5, 18(1929). E. H.

Silicon-manganese steels with chromium additions for engineering applications. A. B. KINZEL. *Trans. Am. Soc. Steel Treating* 14, 866–75(1928).—The susceptibility

to heat treatment and ease of application of heat treatment of 0.35% C, Si-Mn steels are greatly improved by the addn. of 1% Cr as a hardening element. W. A. M.

Effect of quenching and tempering on the hardness and impact resistance of a high chromium-silicon steel. F. T. SISCO. *Trans. Am. Soc. Steel Treating* 14, 859-65 (1928).—A steel contg. 1.2% C, 1.2% Si and 18.0% Cr attains max. hardness when quenched in oil from 1850°F. Quenching below 1600°F. does not harden. Quenching above 2000°F. forms some austenite with lowered hardness and increased toughness. Its hardness is retained at all temps. below 1000°F. Izod values are low and little affected by tempering temps. W. A. MUDGE

Heating high-speed steel to 2400°F. in molten lead. WILBUR C. SEARLE. *Trans. Am. Soc. Steel Treating* 14, 927-30 (1928).—A description of app. and method of heating high-speed steel to 2300-2400°F. in molten Pb. W. A. MUDGE

The system tungsten-carbon. KARL BECKER. *Z. Metallkunde* 20, 437-41 (1928); cf. C. A. 21, 46; 22, 736; 23, 786.—A metallographic and Röntgenographic study of the system W-C. Two methods were used: (I) W and C were melted together in various proportions in a vacuum elec. arc furnace; (II) W wire was heated in an atm. of H_2 or $H_2 + N_2$ to which a definite quantity of CH_4 or C_2H_6 has been added. Under these conditions, the wire begins to take up C at 975°. The expts. show that only 2 carbides are definitely established, WC and W_2C , the latter existing in 2 allotropic modifications with transformation point at about 2400°. The β -form is stable above 2400° and is coarsely cryst. The carbide, W_2C , is considered probable, but its zone of existence ends just below the m. p. On cooling it decomposes to WC and W_2C . W_2C melts without decompn. in an atm. with sufficiently high C pressure, but in vacuum or H_2 it gives up C. On melting WC even in an atm. with high C pressure, C seps., 50% WC and 50% W_2C being formed. X-ray photographs show no appreciable mixed crystal formation between W and W_2C , WC and W_2C , or WC and W. The min. concn. of CH_4 in H_2 which is necessary to carburize W wire increases with increasing temp. from 0.05% at 1850° to 1.25% at 2870°. Up to 1900° WC is the carbide formed, between 1900° and 2400° α - W_2C and above 2400° β - W_2C . The temp. coeff. of resistance of W_2C is small compared with that of W. Thus the resistance of a carburized wire having the compn. W_2C is 11.8 ohms at 20° and 8.93 ohms at 2355°, while with a pure W wire these resistances are 7.47 and 0.56 ohms, resp. H. STOERTZ

Dependence of the elastic coefficient of extension (α) of copper on the previous (heat and mechanical) treatment. W. KUNTZE. *Z. Metallkunde* 20, 145-50 (1928).—The coeff. of extension, α , is the reciprocal of the modulus of elasticity, i. e., the increase in unit length caused by unit load. In Cu test-pieces that have just previously been subjected to plastic deformation, the value of α is subject to hysteresis with loads up to $1/6-1/3$ of the limit of proportionality in the ordinary tensile test, but increases linearly with the load. With greater loads the value of α increases at a greater rate. The effect of drawing on this value is to cause a rapid increase up to a 3% reduction in area, and then a steady decrease. Tempering at low temps. to remove internal stress decreases α , and severely drawn and tempered wires give a lower value for α than annealed wires. Storing at the ordinary temp. for long periods has the same effect on α as a low-temp. tempering. B. C. A.

Significance of the crystal regions α , $\alpha + \beta$, β in the system: copper zinc in the hot-working of alloys. W. MAYER. *Metallbörse* 17, 2357-8, 2469-70, 2525-7 (1927).—All Cu-Zn alloys of the regions α , $\alpha + \beta$, β can readily be worked hot, except M 66 (66% Cu). The grain size is also of decisive significance. Cu-Al alloys are also considered. B. C. A.

Röntgenographs of the refinement of beryllium-copper alloys. O. DAHL, E. HOLM and G. MASING. *Z. Metallkunde* 20, 431-3 (1928); cf. C. A. 22, 1315.—In cooling supersatd. Be-Cu α -mixed crystals, γ -crystals sep. These are cubic body centered, while the α -crystals are regular face centered. To study the process of refinement, the wires (contg. 2.5% Be) were quenched from 800° and annealed at different temps. Annealed at 350°, x-ray pictures show the lines of the γ -lattice after only 10 mins. heating, while after 8 hrs. heating these lines are sharply and plainly seen. If the annealing is carried out at lower temps. the following results are obtained: At 150°, no lines of the γ -lattice appear even after 243 hrs. heating. The lines of the α -lattice, however, show considerable blurring after a few hrs. heating. If the annealing temp. is 200°, the blurring of the α -lattice lines is much quicker and stronger, although the (111) line seems less blurred than the others. After heating at 200° for 50 hrs., the first lines of the γ -lattice appear and are blurred. As the heating is continued, the blurring becomes less, particularly with the γ -lines, and finally both

α - and γ -lines are strong and well defined. The blurring of the lines is attributed to inner strains which are an indication of the heterogeneous character of the process. This is caused by the sepn. of the γ -lattice, and is the first expl. demonstration of the sepn. of a 2nd crystal type coincident with decrease in elec. cond. The blurred character of the γ -lines is due to the high dispersity of the γ -lattice at the beginning of its formation.

H. STOERTZ

Changes in length and modulus of elasticity of beryllium-copper alloys during refinement. O. DAHL AND C. HAASE. *Z. Metallkunde* 20, 433-6(1928); cf. *C. A.* 22, 1315.

Samples of Be-Cu alloy contg. 2.5% Be were quenched from 800° and annealed at 200° and 250° in a dilatometer, elongation, elec. cond. and hardness being measured from time to time. Modulus of elasticity in torsion and cond. of 0.25 mm. wires were detd. for annealing temps. of 150°, 200° and 400° and the results are given in curves. They show that the refining process is of equal influence upon vol. and the modulus of elasticity, the variation in both properties being directly proportional to the quantity of γ -crystals sepd. Even during the first stage of annealing, where elec. cond. decreases, this sepn. is taking place, as indicated by the change in length and modulus of elasticity. The quantity of γ -crystal sepn. is calcd. from the % change in length with the following results: At the point of lowest cond. (after about 1.5 hrs. at 250°) hardness has risen from a Brinell no. of 124 to 253, cond. has fallen 6.2%, length has shortened 0.075%, which is 30% of the total change in length, and the amt. of γ -crystals sepd. therefore represents 30% of the total amt. which finally seps. When the original value of cond. is again attained (4.8 hrs. at 250°), hardness is 325, change in length is 0.135%, modulus of elasticity has increased 9.5 to 10%, and 54% of the total possible γ -crystal sepn. has occurred. At this point the change in modulus of elasticity is 49-52% of the total change.

H. STOERTZ

Changes produced by rolling, hammering and drawing zinc and cadmium. G. MASING. *Z. Metallkunde* 20, 425-7(1928).—On cold working Zn and Cd, changes in the thermal coeff. of expansion are produced. This is related to the change in orientation of the hexagonal axis and varies with the direction in which it is measured. A specimen of cast Zn, 20 mm. diam. with length 1.0, on being rolled to 18 mm. diam., gives for length 1.23, which is identical with the calcd. value for its particular orientation. Rolled to 10 mm. diam., the length is now 4.00 rather than the calcd. value of 2.22, and a change in orientation has occurred. By photomicrographic examn. this is found to be due to twin formation. The increase in the coeff. of expansion becomes less, however, on further working, for the same specimen rolled to 3 mm. diam. has a length of 4.4 compared with the calcd. length of 3.28.

H. STOERTZ

Production and properties of magnesium alloy castings. F. PLAYER. *Metal Ind* (London) 33, 568, 591-2(1928); 34, 6-8(1929); *Foundry Trade J.* 39, 473-6(1928).—E. H.

Relation between drop hardness of nickel and temperature. F. SAUERWALD. *Z. Metallkunde* 20, 408-9(1928).—The drop hardness of pure Ni in a rolled and completely annealed condition begins to fall rapidly at about 300° and drops from 245 mm kg. cu. mm. at 289° to 204° at 388°, after which it rises sharply again, reaches 218 at 449° and then falls slowly. Another peak occurs at about 800°, drop hardness being 175 at 812° as compared with 170° at 711°. The first sudden change in mech. properties at 300° is due to the magnetic transformation point, and the peak at 450° is due to a Ni "blue tone" phenomenon corresponding to that of Fe. S. suggests that the peak at 800° is, perhaps, due to a redistribution of space lattice forces insufficient to produce a crystallographic transformation.

H. STOERTZ

Electrical resistance of a few silver alloys. W. SCHMIDT. *Z. Metallkunde* 20, 400-2(1928).—In Ag alloys which form an uninterrupted series of mixed crystals, a simple relation exists between the elec. resistance, the at. % content of the alloys and their phase diagrams. For Ag alloys with Cd, Mg, Zn, Al, Sn or Sb,

this relation is expressed by the equation $\sigma = \frac{\sigma_{Ag}}{7} (100p)^{\frac{b}{b+8.12}}$, where σ = resistance in ohms. sq. mm./m., and b is the slope of the curve giving the relation between resistance and atomic % of the added element and $= T_s - T_a/p_a$, where T_s is the m. p. of Ag (961.5°), T_a is the temp. at which a heterogeneous mixt. is first formed, and p_a is the compn. in at. %. For Ag-Mn the relation is different and is given by the equation $\sigma = \frac{\sigma_{Ag}}{1.5} (100p)^{0.85}$. Drawing produces a large increase in the elec. resistance of these alloys.

Mechanical properties of crystals of a refinable aluminum alloy. G. SACHS. *Z.*

Metallkunde 20, 428-30(1928).—A discussion of the relation of mech. properties of Al alloys (contg. 5.0% Cu) to recrystn. phenomena, and the significance of x-ray photo-graphs. H. STÖRTZ

Theory of metallic corrosion in the light of quantitative measurements. II. G. D. BENGOUGH, J. M. STUART AND A. R. LEE. *Proc. Roy Soc. (London)* A121, 88-121(1928).—Corrosion-time curves were detd. for annealed Zn in cond. H₂O and KCl solns. The curves usually have a short branch from zero time to 2 or 3 days in which they are concave upwards. After the initial period they become exponential, providing the O₂ supply is sufficient. If the supply of O₂ is inadequate the curves approach a straight line. The concn. of ions in soln. and phys. condition det. the value of the exponents. Corrosion increases with KCl concn. to a max. and falls off when the soln. is nearly satd. In solns. stronger than 0.0001 N KCl, H₂ is evolved, causing discrepancies between the total-corrosion and O₂-absorption curves. The proportion of corrosion due to H₂ varies from 5 to 15%. The total amount of corrosion that has occurred when the corrosion-time curves of KCl soln. have become nearly horizontal is independent of the O₂ supply but depends upon (1) the concn. of the soln. and (2) the rate of withdrawal of Cl ions from current-carrying capacity either by pptn. or by some other process. The effect of pptd. corrosion products on the rate and total amount of corrosion is very small for periods up to 100 days. B. E. ROETHLI

Furnace lining (Ger. pat. 469,863) 19.

Treatment of complex ores. FRANCES M. SIMONDS (half interest to A. F. Hyder Can. 286,360, Jan. 8, 1929. Ground ores contg. sulfides of Fe, together with sulfides of Cu, Pb and Zn, are heated and a slightly oxidizing gas is passed therethrough for a relatively long time, and then for shorter periods reducing gases and oxidizing gases in alternation; the mass is heated for a relatively long period in a reducing atm. and then cooled in a non-oxidizing atm., the cooled mass is mixed with water, and SO₂ passed through the mixt.; the mixt. is filtered, the residue concd., and the Fe sep'd from the filtrate.

Treating low-grade ore such as cassiterite. R. ANTHOING. Brit. 292,832, Nov. 7, 1927. The ore is treated with a reducing gas such as lighting gas, producer gas or coke-oven gas at a temp. of 300-900° and then concd. by flotation.

Flotation of graphite and other ores. JEAN F. M. R. DE ROBILLARD. Fr. 33,297, Feb. 17, 1927. Addn. to 628,036. The openings described in Fr. 628,036, on which the water jets are directed, are large and covered with metallic gauze or other filtering material. Cf. C. A. 22, 2349.

Roasting ores. COMPAGNIE DES MÉTAUX OVERPELTLOMME. Fr. 643,274, Nov. 2, 1927. Fine ores are mixed with coal, etc., and made into measured grains and afterwards submitted in a permeable layer to roasting and agglomeration on a furnace hearth with air drawn through. The ore may be moistened with water or treated with a binding agent and dried. Fr. 643,275 describes such a treatment of Zn ores. Cf. C. A. 22, 4450.

Smelting ores in reverberatory furnaces. GEORGE W. PRINCE (to United Verde Extension Mining Co.). U. S. 1,700,515, Jan. 29. Ore is deposited along the bottom of the furnace chamber from points spaced from the side walls and fettling material is blown from the firing end wall of the furnace chamber into the space between the smelting ore and the side walls of the furnace chamber, to protect the side walls from the action of the smelting ore and from the intense heat in the chamber.

Reduction of ores. GRANULAR IRON CO. Fr. 642,805, July 28, 1927. An app. for the reduction of Fe ore without fusion, in which the powd. ore is heated to a point

below fusion and then a powd. carbonaceous fuel is mixed therewith with agitation, comprises an inclined cylinder for treating the charge and means disposed at the entrance to accelerate the rapid movement of the charge in the cylinder. Ores of Zn, Pb and Cu may be similarly treated.

Utilization of ore lyes. METALLBANK UND METALLURGISCHE GESELLSCHAFT, A.-G. Fr. 643,733, Nov. 10, 1927. Cu is extd. from ore lyes by cementation with the aid of Fe, while Zn is extd. from the lyes free from Cu and sulfates by coke-oven gases contg. H_2S , and the Fe is then recovered by treating with chalk and oxidizing agents. Part of the sulfates is removed by freezing and the rest by adding $CaCl_2$.

Chromium ore. I. G. FARBENIND. A.-G. (Paul Weise, inventor.) Ger. 469,910, Apr. 25, 1925. Powd. Cr ore is decompd. by an alkali to which Fe_2O_3 and Mg oxide added. The latter are recovered and used again.

Chromium. BOZEL-MALETRA (Soc. industrielle de produits chimiques). Fr. 511, Apr. 6, 1927. Cr ores are treated with alkalies or alk. agents, with or without salts, in furnaces of the type used for roasting pyrites, having agitators permitting stirring up of a thin layer, and being on one or several floors. The heating may be direct contact with the fuel or by external heating.

Zinc. FRÉDÉRIC LEDOUX and PAUL VÉROLA. Fr. 643,483, Apr. 4, 1927. Zn ores coming from the metallurgical treatment of Zn ores are treated in water with H_2SO_4 to form $ZnHSO_4$, which may be calcined to a white oxide for use in paint, or may be used for the production of Zn by electrolysis or may be oxidized to $ZnSO_4$.

Recovery of light metals. I. G. FARBENIND. A.-G. Fr. 33,249, Mar. 21, 1927. In. to 543,215. In the recovery of light metals from machinery or foundry waste, an acid bath of anhyd. $CaCl_2$ contg. 18% CaF_2 is used.

Solidifying and freeing molten metals from gas. N. N. JAROTZKY. Ger. 470,195, Apr. 25, 1926. An app. is described in which the vessel contg. the metal is mounted to rotate about both a vertical and a horizontal axis.

Molding. HERMANN MEISNER. Ger. 470,233, Nov. 18, 1927. A non-metallic mold for castings is made by using a dismountable mold with a suitably shaped interstice, and then filling the mold with quickly setting material such as cement or gypsum.

Molding. MAYBACH-MOTORENBAU G. M. B. H. Ger. 470,234, July 4, 1926. A slush of white metal is applied to a casting by a mold fitting round it.

Molding metals. SIEGFRIED JUNGHANS. Ger. 470,198, Mar. 30, 1927. The central kernel of castings is loosened by subjecting the casting to short steady pressures in different directions in order to take advantage of the elasticity and compression differences of the 2 metals.

Metal molding. MADISON-KIPP CORP. Ger. 470,197, Nov. 12, 1925. A squirting machine which operates automatically as the mold is filled and emptied is worked by the same gas pressure and from the same power device as that which opens and closes the mold.

Coating for protecting metal molds. HARRY P. KIMBER (to Earl Holley). U. S. 1,701,159, Feb. 5. Coatings are formed of an inert refractory material such as insulating earth and a small proportion of $AlCl_3$ which is used merely as a binder. Cf. U. S. 1,612,809.

Billet-mold. TANNIE LEWIN (one-half to William Lewin). U. S. 1,701,721, Feb. 12. Structural features.

Apparatus and method of scouring molding sand to prepare it for reuse. EDWARD W. CAMPION and ARTHUR H. DIERKER (to Buckeye Steel Castings Co.). U. S. 1,700,713, Jan. 29.

Apparatus for casting with separable chills. IRA D. TRAVIS. U. S. 1,700,341, Jan. 29.

Chilled cast iron roll. CHARLES I. NIEDRINGHAUS and LEWIS W. MESTA (to Mesta Machine Co.). U. S. 1,702,128, Feb. 12. Chilled cast iron rolls contain C 2.4, Si 1.8-4, P not over 0.3, S not over 0.2, Mn 0.1-1.5 and Si 0.5-2.5%; the Si, C and Cr are so proportioned that a chill is produced contg. a small but appreciable quantity of very finely divided graphitic C and the chill merges gradually and without abrupt change of grain structure into a core of mottled iron which has a greater tendency toward white iron than that of the usual chilled iron roll.

Rolling metals into long strips. AMERICAN ROLLING MILL CO. and J. B. TYTUS. Brit. 293,229, Sept. 1, 1927. Mech. features.

Rendering nickel forgeable by adding vanadium and magnesium in small quantities. JOHN H. WHITE (to Bell Telephone Laboratories). U. S. 1,700,460, Jan. 29.

Open-hearth metallurgical furnace construction. B. TALBOT. Brit. 293,010, June 30, 1927.

Shaft furnace. FRITZ HENFLING. Ger. 470,282, Mar. 29, 1928. Feelers are mounted in chambers up the shaft to ascertain the height of the charge.

Metal-sweating furnace. TANNIE LEWIN. U. S. 1,701,722, Feb. 12.

Center flame furnace for the purification of steel. JUVÉNAL MAXIMOFF, MARIE STELLA DE COSTA (NÉE VINCENT) and ROBERT KREBS (called Lue Gallicanne). Ger. 470,228, Mar. 31, 1926. The furnace rotates on a vertical axis and is heated from below by a gas nozzle.

Explosion trap for blast furnaces. KÖLSCH-FOLZER-WERKE, A.-G. and PAUL NÖRZEL. Ger. 469,966, Dec. 8, 1926.

Blast-furnace dust and slime. DE WENDEL ET CIE. Fr. 643,530, Apr. 8, 1927. The dust or slime is made into a molten siliceous slag by heating to fusion in an oxidizing medium in a furnace, *e. g.*, a reverberatory furnace, a mixt. contg., *e. g.*, dust 60-70, siliceous sand 20-25, scales from rolling machines 20-5%.

Purifying cast iron. A. F. MEEHAN (to Meehanite Metal Corp.). Brit. 292,164, June 16, 1927. Gray molten cast iron is purified by adding to it silicides substantially free from Fe such as those of Ca or Mg and Ba. A small proportion of Fe may also be added as may also Ni, Al, Cr, Ti or V.

Testing the rusting properties of iron, etc. C. MAULER. Brit. 292,794, July 28, 1927. Specimens are immersed in a soln. which is formed of an alkali such as NaOH or KOH and an oxidizing agent such as a nitrate, permanganate, dichromate, peroxide or aromatic nitro compd. and the temp. is noted at which the first signs of corrosion appear on the metal.

Rustproofing iron, steel, etc. W. H. COLE. Brit. 292,666, March 19, 1927. The articles treated are placed in a revolving sealed container together with a mixt. such as that formed from emery, dry Cu-Zn ppt., Sn and Al, and may be heated, first to 600°, then at about 500° and afterward at about 350°. The Zn-Cu ppt. may be prepd. by reaction of Zn dust on CuSO₄ soln. Various metal salts or fluxing agents also may be added. Cf. C. A. 23, 811.

Low-carbon steel. ADOLF FRY (to Fried. Krupp A.-G.). U. S. 1,700,674, Jan. 29. Low-C steel is rendered less liable to change from aging and less liable to destruction of texture by the action of liquids, gases and vapors, by quenching at a temp. above 650°.

Conditioning articles of manganese steel. GEORGE R. HANKS (to Taylor-Wharton Iron and Steel Co.). U. S. 1,701,976, Feb. 12. Alloy steel shapes such as railway car wheels contg. 10-15% Mn are conditioned by subjecting the areas normally exposed to service self-conditioning to selectively gaged shocks applied while the article is cold and before it is put into service.

Cleaning steel preliminary to painting it. JAMES D. KLINGER and CLETE L. BOYLE. U. S. 1,700,739, Feb. 5. The surface is treated with a rust-removing acid such as H₃PO₄ and with the monoethyl ether of ethylene glycol (suitably in about equal proportions). Water or methyl ethyl ketone may be added. Cf. C. A. 22, 1833.

Heat-treating metals and alloys. WILLOUGHBY S. SMITH, HENRY J. GARNETT and JOHN A. HOLDEN. U. S. 1,700,547, Jan. 29. Articles such as wires, tapes or cables are passed through a heating tube and an inert gas such as N is supplied to the tube at 2 points so that the gas supplied at one point will flow to the atm. at the inlet end of the heating tube and serve to dispel volatilized matter and the gas supplied at the other point will flow to the outlet and prevent oxidation and reduction. U. S. 1,700,548 relates to an *app.* for similar operations.

Alloys. WILLOUGHBY S. SMITH, HENRY J. GARNETT and JOHN A. HOLDEN. Fr. 643,376, Nov. 5, 1927. Alloys suitable for the manuf. of telegraphic conductors contain Fe 55-65, Ni 32-42, Si or Al 1-4, and 1-4% of Cr, W, Mo or V. Up to 1% of Mn may be added. Cf. C. A. 23, 1103.

Alloys. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 643,416, Nov. 7, 1927. An alloy for use in elec. app., particularly starting rheostats of elec. motors, contains Fe 80, Al 4-6, Cr 12-14, C less than 0.1, Si 1, Mn 1%.

Alloys. I. G. FARBENIND A.-G. Brit. 291,522, March 3, 1927. One at least of the components of specified alloys is derived from decompn. of the corresponding carbonyl compd. (which may be effected in a melt contg. the other components of the alloy). Various alloys are described, among which are alloys of Fe and Ni; Fe and Si; Fe and Cr, Co, Mo, or Ni and C; and Fe, Cr and C.

Alloys. I. G. FARBENIND A.-G. Fr. 643,041, Oct. 27, 1927. An alloy resistant to corrosion, hard and not brittle is made by melting 91% of Pb and 9 of Sb with the addn. of 0.25% Al, casting and rapidly cooling.

Alloys. THE INTERNATIONAL NICKEL COMPANY. Fr. 642,140, Oct. 10, 1927. A gray cast iron, resistant to wear, contains C 2-4, Si 0.25-3, Mn 0.25-2, Ni 1.5-12 and Cr up to 3%, or C 2.75-3.5, Si 0.5-1.5, Mn 0.5-0.8, Cr up to 2%, with or without Ni 1-2%. Cf. C. A. 23, 812.

Alloys. LE MAGNÉSIUM INDUSTRIEL. Fr. 642,776, Mar. 31, 1927. A Mg alloy having a good heat cond. and capable of being forged, e. g., for motor pistons, contains Mg 93, Al 2, Cu 4 and Cd 1%. Forging is effected after bringing the piece to 485° for a time sufficient for the mol. state of the piece to become homogeneous.

Heat-treating aluminum alloys. H. C. HALL and T. F. BRADBURY. Brit. 292,407, Nov. 5, 1927. The alloys described in Brit. 281,912 (C. A. 22, 3624) are heated to 160-190° for at least 20 hrs. and then quenched.

Improvement of aluminum alloys. WILHELM SANDER and WILLIAM GUERTLER (to Th. Goldschmidt A.-G.). Can. 286,100, Jan. 1, 1929. To produce alloys of high tensile strength, Al is alloyed with 4-26% by wt. of MgZn₂, minor quantities of elements having high melting points (Ni, Ti, W, Mo and the like not exceeding 1%) are added, also minor quantities of elements forming solid solns. with Al, and the alloy is annealed, quenched and aged. Max. strength is obtained after storing at room temp. for 5 to 8 days if the alloys are further heated to temps. between 50° and 150° for 3 to 48 hrs.

Alloys of copper, antimony and lead. S. DRICHES. Brit. 292,936, June 24, 1927. Various alloys of Cu, Sb and Pb are improved by the addn. of elements such as Al, alk. earth metals, Be, Mg, Bi, alkali metals, Co, Fe, Mn, Ni, Sn, or Zn, or of P, Si and S, with or without further addn. of As, Cd or Hg. The alloys may be heated for some time slightly below the hardening point and then quenched.

Tantalum-alloy pen. EDGAR W. ENGLE and MINER M. AUSTIN (to Fansteel Products Co.). U. S. 1,701,299, Feb. 5. Pens are made with nibs of Ta 90 and W 10%.

Steel alloys. F. KRUPP A.-G. Brit. 292,937, June 23, 1927. Steel alloys, the yield point of which cannot be increased by heat treatment such as an austenitic Ni-Mn steel, are hot-worked as by rolling or forging to a hollow form and machined to form an over sized body which is then expanded as by a mandrel to induce a stress in excess of the original yield point. The body is then further machined to produce the desired article, e. g., a winding protection cap for a turbo rotor.

Steel alloys. F. KRUPP A.-G. Fr. 642,942, Oct. 24, 1927. The elastic limit of steel alloys, particularly austenitic steel, is increased by a heat treatment and by turning, in the form of hollow bodies of revolution and these bodies are brought by a centrifugal app. to a high speed of rotation so that the effort thus engendered increases the elastic limit. Addnl. weights may be placed in the bodies to increase the effect. Cf. C. A. 23, 813 and preceding abstract.

Working metals. BERNDORFER METALLWARENFABRIK ARTHUR KRUPP A.-G. Austrian 111,513, July 15, 1928. Operations such as forging, pressing, and drawing are conducted in a liquid bath maintained at the optimum temp. for the process in view. Suitable app. is described.

Case-hardening metals. P. W. SHIMER and E. B. SHIMER. Brit. 292,557, June 22, 1927. In effecting case-hardening by immersion in a bath of fused salts, a CN compd. is added in small quantities at frequent intervals. NaCN or Ca cyanamide or the compd. formed by the fusion of Ca cyanamide and NaCl may be used in a proportion of about 0.25% the wt. of the bath.

Etching aluminum. GÉZA SAILER. Ger. 469,851, Feb. 19, 1927. Sol. derivs. of indigoes, fatty acids, vegetable gum or mixts. of these are added to the alkali lye used for etching Al or its alloys.

Toughening and hardening taps for cutting screw threads, etc. REGINALD F. KNIGHT and FREDERICK LYNCH. U. S. 1,701,570, Feb. 12. See Brit. 281,384 (C. A. 22, 3389).

Sheets or strips of metals such as brass. OTTO JUNKER. U. S. 1,701,889, Feb. 12. A metal block or ingot heated to a temp. to give it a moldable condition is subjected to the action of a cutting tool which "peels off" sheets or strips of the metal.

Metal foil. A. F. G. KLUGE, J. V. W. WINTER and W. G. PINNER (trading as Kluge and Winter). Brit. 292,459, June 18, 1927. Two or more metal leaves are united by interposed leaves of rubber, gutta-percha or like material. The material may be used for packing, manuf. of artificial flowers, etc.

Protecting pipe from corrosion. HOMER S. BURNS and LYMAN S. BUSHNELL (to Freeport Sulphur Co.). U. S. 1,700,995, Feb. 5. Pipes such as those used in S mining are treated with a soln. of salts of Ca and Mg such as sulfates and bicarbonates or sea water which will ppt. out of soln. and a protective scale is formed on the pipe by such

pptn. An app. is described. U. S. 1,700,996 (L. S. BUSHNELL) also specifies an app. and method of procedure of similar character.

Use of a travelling fluctuating electric arc for cutting metals. OSKAR F. A. E. GRUMPELT (to Elektrotrennmashinen G. m. b. H.). U. S. 1,701,919, Feb. 12.

Annealing flat strips of metal. H. W. BROWNSDON and KYNOCH, LTD. Brit. 292,690, March 25, 1927. Heat exchange is effected between annealed metal and cold metal. Various mech. features are described.

Apparatus for annealing, welding, etc., by use of heat concentrated by a lens or reflector. E. SCHRÖDER. Brit. 292,985, June 28, 1927.

Solder. AMERICAN MACHINE AND FOUNDRY CO. Fr. 642,979, Oct. 25, 1927. See Can. 285,319 (C. A. 23, 593).

Solder for aluminum. LA LHOCORYNE (S.A.R.L.). Fr. 642,778, Mar. 31, 1927. A solder for Al contains ZnCl_2 90, NH_4Br 8, and NaF 2%. If an addn. of material is necessary sticks of solder composed of an alloy of Al, Zn and Sn are used.

Soldering metals. NAAMLOOZE VENNOOTSCHAP PHILIPS' GLOEILAMPENFABRIEKEN Fr. 643,450, Nov. 7, 1927. See Brit. 289,553 (C. A. 23, 595).

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Recent advances in science: Organic chemistry. J. N. E. DAY. Univ. London. *Science Progress* 23, 211-6(1928).—A review of recent work on org. compds. of As, Au, Hg, Pt and Tc. JOSEPH S. HEPBURN

Industrial significance of some recent developments in organic chemistry. ARTHUR D. LITTLE. *Science* 68, 501-3(1928). E. M. S.

The significance of Wöhler's urea synthesis, a century of chemical synthesis. P. WALDEN. *Naturwissenschaften* 16, 831-49(1928).—An extensive historical review. B. J. C. VAN DER HOEVEN

Formation of gaseous and liquid hydrocarbons by the action of steam and alkali on semicoke. F. FISCHER AND H. PICHLER. *Brennstoff-Chem.* 9, 200-6(1928).—Semicokes from bituminous coal, brown coal and charcoal were treated with water in an autoclave with and without addn. of alkali at temps. 380-500°. CH_4 and a small quantity of its homologs together with much CO_2 and H_2 and some CO were formed when H_2O alone was used but the reaction fell off with time, because of decreased activity of the coke. Addn. of KOH and NaOH renews coke activity. These not only catalyze the reactions but also serve to absorb CO_2 formed. Na_2S , Na_2CO_3 , $(\text{NH}_4)_2\text{CO}_3$ and CaO were not effective as catalyzers although the carbonates and CaO absorbed CO_2 . Fe_2O_3 , Fe and Ni salts were also inactive. By continued treatment with H_2O and KOH 82% of a brown-coal semicoke was converted into CH_4 , CO_2 and H_2 and it seemed possible to so convert all the coke. Forty g. brown-coal coke + 360 g. KOH was heated for 13 hrs. at 480° (the max. pressure being 265 atms.), with a yield of 3.5 g. ether-sol oil and 25 l. gas of the following compn.: satd. hydrocarbons 1.6, H_2 43.4, CH_4 44.5, C_2H_6 10.5%. This was the best result obtained. J. D. DAVIS

Reactions between the anhydrous aluminum chloride and the olefinic hydrocarbons. ANTONI SZAYNA. Lwow Polytech. *Przemysl Chem* 12, 637-47(1928).—Olefinic hydrocarbons, i. e., ethylene, propylene, isobutylene, octene and diamylene were subjected to reaction with Al_2Cl_6 at 100° and 150°. C_2H_4 reacts under such conditions with difficulty and gives few heavy products. Other olefins give as products a gas, liquid hydrocarbons and a metallo-org. compd. The gas is composed exclusively of butane, and only in the case of propylene and perhaps also diamylene at 150° it contains also a little propane. Liquid hydrocarbons in lower fractions are composed of paraffins, in heavier fractions of naphthenic hydrocarbons. There are also present small quantities of the unsatd. hydrocarbons. In distn. they show well developed max. which indicate the existence of polymerization and privileged points of attack on the mol. The metallo-org. compd. is a deep brown, very viscous oil which is decompd. by water with formation of heat. Its empirical formula is $(\text{AlCl}_2\text{C}_4\text{H}_8)_n$. An org. oil extracted from this compd. corresponds to the formula $(\text{C}_8\text{H}_{12})_n$ or $(\text{C}_8\text{H}_{14})_n$. Its properties indicate the existence of cyclic non-satd. hydrocarbons. A. C. Z.

Polymerization. XI. Polymerization and depolymerization of amylenes under the influence of silicates. S. V. LEBEDEV AND I. A. VINOGRADOV-VOLZYNSKI. *J. Russ. Phys.-Chem. Soc.* 60, 441-52(1928).—A mixt. of amylenes, consisting of $\text{Me}_2\text{C}:\text{CHMe}$ and methylethylethylene, yielded when heated with floridin (a silicate activated by

heating at 300–50°) diamylene, b. 37–9°. This product when heated at 150–60° with floridin yielded gaseous and liquid products. The former consists of 8.25% of CH_4 and 91.4% of a mixt. of iso- and ψ -butylenes, with possibly traces of propylene. The liquid products consisted of $\text{Me}_2\text{CHCH}:\text{CH}_2$, isopentane, $\text{Me}_2\text{C}:\text{CHMe}$, γ -methyl- Δ^2 -pentene, b. 67–9°, heptylene, octylene and nonylene. B. C. A.

The alcohols. High-pressure synthesis. R. H. HOPKINS. *Times Trade and Eng. Supplement* (London) 23, 34(1928).—A review of processes, patents and work by the Department of Scientific and Ind. Research. Three cuts. E. M. SYMMES

Methanol. Its synthesis. E. AUDIBERT. *Tech. moderne* 20, 861–6(1928); cf. C. A. 22, 4461.—The catalysts in use are CuO and ZnO . CuO is the more active but is easily affected by the formation on its surface of substances of higher mol. wt. To prevent this, H is increased to $\text{CO} + 5\text{H}_2$. A long exposure to high temp. decreases the activity of catalysts. The activity is also affected favorably or adversely by the presence of other metallic oxides. Yields are roughly proportional to the square of the pressure. ZnO requires higher pressures than CuO . Maximum yields are obtained when the mixt. of gases is equal to $\text{CO} + 2\text{H}_2$. MeOH being an intermediate product, greater yields of MeOH to the exclusion of other products are obtained when the speed of the gases through the catalyst chamber is increased. Secondary reactions are increased with higher temp. CuO permits the use of lower temp. Both oxides are subject to poisoning. P. THOMASSET

Formation of primary amines from Grignard reagents and monochloroamine. II. GEORGE H. COLLEMAN AND CHARLES B. YAGER. *J. Am. Chem. Soc.* 51, 567–9(1929); cf. C. A. 22, 1950.—A further modification of the prepn. of NH_2Cl is described. By use of the previously described method, the following yields of primary amine and NH_3 were obtained from the Grignard reagents named, the 3 sets of values being for N, Cl, Br and I, resp.: iso- $\text{C}_3\text{H}_7\text{MgX}$, 65.5, 29.5; 37.2, 54.7; 9.0, 79.0; sec- $\text{C}_4\text{H}_9\text{MgX}$, 70.0, 20.0; 51.1, 38.9; 15.8, 74.13; sec- $\text{C}_5\text{H}_{11}\text{MgX}$, 71.7, 19.0; 31.6, 61.9; 13.7, 79.13; tert- $\text{C}_4\text{H}_9\text{MgX}$, 60.2, 39.0; 20.24, 79.7; 4.8, 81.4; tert- $\text{C}_5\text{H}_{11}\text{MgX}$, 66.2, 30.9; 14.25, 79.2, 2.0, 80.2. These yields are much the same as with reagents prepd. from primary halogen compds. C. J. WEST

Behavior of alcoholate solutions towards nitric oxide. HEINRICH WIELAND (WITH J. CHAVAN AND F. KLAGES). *Bayr. Akad. Wiss. Munchen. Ber.* 61B, 2382–7 (1928). The formation of $\text{CH}_3\text{N}(\text{ONa})\text{NO}$ (I) from NO and NaOEt in EtOH was ascribed by Traube, who believed that the reaction was characteristic for ketones and compds. with active Me and CH_2 groups in general, to the presence of Me_2CO in the EtOH . Many yrs later Stechow concluded that the reaction cannot be used to detect ketones with the grouping MeCO in EtOH , because I is formed from NO and alk. EtOH alone so rapidly that no conclusion can be drawn as to its origin when it is obtained with any given soln. under investigation. Like Traube, he ascribed its formation to Me_2CO which is supposed to be produced in alcoholate solns., even in the absence of air. For this supposed formation of Me_2CO in such solns., however, there is not a shadow of evidence. As a matter of fact the I is formed from AcH :

$$\text{AcH} + 2\text{NaOEt} + 4\text{NO} \longrightarrow [\text{ON}(\text{NaO})\text{N}]_2\text{CHCHO} + 2\text{HOEt} \xrightarrow{\text{NaOH}} \text{I} + \text{HCO}_2\text{Na}.$$

The AcH is formed by dehydrogenation of the EtOH by the NO : $\text{EtOH} + 2\text{NO} \longrightarrow \text{AcH} + \text{N}_2\text{O} + \text{H}_2\text{O}$. The H_2O (or NaOH) produced hydrolyzes the I, so the reaction may be more correctly written: $3\text{NaOEt} + 6\text{NO} \longrightarrow (\text{NaO}_2\text{N})_2\text{CH}_2 + \text{HCO}_2\text{Na} + 2\text{EtOH} + \text{N}_2\text{O}$. The expts. were carried out in a shaking app. connected with a graduated gas container so that the velocity of the absorption of the NO and the relation between the quantities of gas absorbed and I formed could be followed. The NO is at first absorbed quite rapidly at 20°; 100 cc. of 10% KOEt in the 1st 4 hrs. absorbed nearly 11 NO per hr. The absorption then becomes slower, but if the app. is evacuated and NO is then admitted again, the absorption is almost as rapid as before. The retardation is due to the evolved N_2O which continually decreases the concn. of the reacting NO . The velocity of the reaction is detd. by the dehydrogenation of the EtOH which is the main reaction. PhCH_2OH in the presence of benzylate is dehydrogenated much more rapidly than EtOH ; in this case the resulting BzH cannot react with the NO to form an isonitramine salt. iso- PrOH also apparently reacts more rapidly than EtOH . MeOH does not seem to react with NO . The HCO_2H was detd. by removing the NO in the reaction mixt. by long evacuation, dissolving the salts in a little H_2O , shaking overnight with freshly pptd., well washed $\text{Pb}(\text{OH})_2$, filtering off the insol. Pb salt of the diisonitramine, acidifying the filtrate with H_2SO_4 , distg. until the distillate is no longer acid, making the distillate acid with HCl , refluxing for a time with excess of HgCl_2 and weighing the pptd. HgCl_2 . C. A. R.

Thermal decomposition of sodium ethyl. WALLACE H. CAROTHERS AND DONALD D. COFFMAN. E. I. Du Pont de Nemours and Co., Wilmington, Del. *J. Am. Chem. Soc.* **51**, 588-93(1929).— HgEt_2 reacts completely with an excess of Na *in vacuo* with the formation of NaEt . The thermal decompn. of NaEt (in the presence of Na and Hg) begins very slowly at room temp. and is quite rapid at 100° . The gas formed in this decompn. at temps. in the neighborhood of 90 – 100° consists of C_2H_4 and C_2H_2 in the ratio of about 85 to 15. NaH is found in the residue. The principal reaction is, therefore, $\text{NaEt} \rightarrow \text{NaH} + \text{C}_2\text{H}_4$. The gas formed by the spontaneous decompn. of NaEt at ordinary temp. contains more C_2H_2 than C_2H_4 . This is supposed to be due to the reaction $2\text{NaEt} \rightarrow \text{Na}_2\text{C}_2\text{H}_4 + \text{C}_2\text{H}_4$. The analytical data furnish some information concerning the fate of the $\text{Na}_2\text{C}_2\text{H}_4$. C. J. WEST

Preparation of zinc alkyls and their use in the synthesis of hydrocarbons. C. R. NOLLER. Northwestern Univ. *J. Am. Chem. Soc.* **51**, 594-9(1929).—A general procedure is given for the prepn. of Zn alkyls; the yields are increased if the distn. of the crude reaction mixt. is carried out *in vacuo*; a mixt. of alkyl iodide and bromide may be used in place of pure iodide, in the case of ZnEt_2 , while with the higher Zn derivs., a smaller proportion of iodide is necessary. The following b. ps. and yields are reported: ZnEt_2 , b. 112 – 7° , 87 – 9% ; ZnPr_2 , b. 39 – 40° , 85 – 6% ; Zn dibutyl, b. 81 – 2° , 78 – 9% ; $\text{Zn}(\text{iso-Am})_2$, b. 100 – 3° , 50 – 5% . For condensation the Zn deriv. is used with an equal wt. of xylene or tetralin. Only tertiary alkyl halides react with these Zn alkyls. By use of the above Zn alkyls and tert-BuCl , the following hydrocarbons were prepd.: Me_3CEt , b. 49.5 – 50.5 , d_4^{20} 0.6512 , n_D^{20} 1.3675 , mol. ref., 29.6 , 45% yield (without solvent, 18%) (this order of properties will be used below); Me_3CPr , 80 – 1° , 0.6778 , 1.3828 , 34.4 , 40% ; trimethylbutylmethane, 106 – 7° , 0.6967 , 1.3931 , 39.0 , 36% ; $\text{Me}_3\text{C}(\text{iso-Am})$, 121 – 3° , 0.7091 , 1.3997 , 43.7 , 25% ; Me_2CEt_2 (from tert-AmCl), 86 – 6.5° , 0.6952 , 1.3908 , 34.2 , 51% ; Me_2EtCPr , 111 – 2° , 0.7116 , 1.3998 , 38.8 , 24% ; dimethylethylbutylmethane, 137 – 8° , 0.7304 , 1.4095 , 43.3 , 29% . C. J. WEST

Electrolysis of metallo-organic compounds. WORTH H. RODEBUSH AND J. MERRIAM PETERSON. Univ. of Illinois. *J. Am. Chem. Soc.* **51**, 638-9(1929).—Brief note on the electrolysis of EtMgBr and ZnEt_2 . ZnEt_2 shows no appreciable cond. in the pure state but in Et_2O the sp. cond. is 10^{-4} . With a potential of 110 v. appreciable quantities of Zn were deposited on the cathode; the products at the anode were not satisfactorily identified but there can be little doubt that the Et radical was liberated at the anode. C. J. WEST

The slow oxidation of oleic acid with hydrogen peroxide. ALFONSO CRUTO. Nat. Med. Pharmacol. Inst. "Sersono." *Biochim. terap. sper.* **15**, 180-9(1928).— Na oleate in slightly alk. soln. (p_H 7.58) was treated with H_2O_2 after addn. of a small quantity of FeSO_4 . The soln. was kept at 37 – 40° for several days. Since acids were formed during the oxidation, the p_H was kept const. by adding NaOH from time to time; also the H_2O_2 concn. was kept approx. const. The products formed in the oxidation amounted to 10% of the initial quantity of oleic acid; they were found to be identical with those obtained when the reaction was allowed to take place at water-bath temp. In the latter case the yield was better and the reaction velocity was greater. By the latter method there were obtained from 50 g. oleic acid and 100 cc. H_2O_2 : small quantities of HCO_2H , AcOH , $\text{MeCH}_2\text{CH}_2\text{CO}_2\text{H}$ and other acids of low mol. wt., $\text{HO}_2\text{C}(\text{CH}_2)_7\text{CO}_2\text{H}$, 3.5 g. $\text{Me}(\text{CH}_2)_7\text{CHO}$, 2 g. $\text{Me}(\text{CH}_2)_7\text{CO}_2\text{H}$ (I), 4.05 g. of derivs. of I, probably consisting of a mixt. of θ -hydroxynonoic acid (II) and $\text{OHC}(\text{CH}_2)_7\text{CO}_2\text{H}$ (III), 0.25 g. $\text{Me}(\text{CH}_2)_7\text{CH}(\text{OH})\text{CH}(\text{OH})(\text{CH}_2)_7\text{CO}_2\text{H}$ and 3.80 g. of an acid (IV) with the sapon. no. 188.8 and the probable formula $\text{C}_{18}\text{H}_{34}\text{O}_3$. IV is a very viscous, slightly yellowish compd.; it cannot be distd. without decompn. Its mol. wt. was found to be 272 and 279 , resp. By treating IV in the usual manner with H_2O_2 in slightly alk. soln., II and III were obtained. On the basis of his expts., C. develops a theory explaining the oxidation process of the satd. fatty acids. The degradation is assumed to proceed according to the following scheme: $\text{RCH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H} (-2\text{H}) \rightarrow \text{RCH}_2\text{CH}:\text{CHCO}_2\text{H}$ ($+O$) $\rightarrow \text{RCH}_2\text{CH}=\text{CHCO}_2\text{H} (+\text{H}_2\text{O}) \rightarrow \text{RCH}_2\text{CHO}$ (V) + $\text{HOCH}_2\text{CO}_2\text{H}$ (VI);

G. SCHWOCH

Action of hydriodic acid on tetraphenylbutinediol. YU. ZALKIND AND A. KRUGLOV. Mediz. Inst., Leningrad. *Ber.* **61B**, 2306-12(1928); cf. C. A. **21**, 56.— $(\text{HOCPh}_2\text{C} :)_2$ (I) behaves quite differently from $(\text{HOCMe}_2\text{C} :)_2$ with HI . With 10 – 2% aq. HI on the H_2O bath I gives chiefly the expected $2,2,5,5$ -tetraphenyl-3-iodo-2,5-dihydrofuran (II), which gives no gas with MeMgI (absence of any HO group) and is oxidized by

KMnO_4 in Me_2CO to Ph_2CO , CO_2 and $\text{Ph}_2\text{C}(\text{OH})\text{CO}_2\text{H}$; together with the II is formed small quantity of a yellow hydrocarbon $\text{C}_{21}\text{H}_{20}$ (III). With a satd. soln. of HI in H_2O or AcOH at 0° , I and II give III as the chief product; at $5-15^\circ$ there is formed simultaneously a small quantity of an isomeric orange hydrocarbon (IV), the yield of which is increased to 60–80% under more rigorous treatment (I, II or III with concd. II on the H_2O bath); at the same time there are sometimes formed very small quantities of $(\text{Ph}_2\text{C}:\text{CH})_2$. III and IV are identical with Brand's $(\text{Ph}_2\text{C}:\text{C})_2$ and 1,10,10-triphenylbenzofulvene, resp. II, m. $139-40^\circ$, mol. wt. in C_6H_6 530–4. III, m. 235° , mol. wt. in camphor 356–73. IV, m. $205-6^\circ$, mol. wt. in camphor 355–7; 0.5 g. with 5 g. Pt sponge in 60 cc. Et_2O under a slight overpressure (about 40 cm. of H_2O) absorbs 4 atoms of H in 122 min., giving 1-phenyl-3-[diphenylmethyl]dihydroindene, small crystals, m. 135° , from concd. alc. soln., large crystals, m. 107° , when crystd. slowly; the latter, on solidification, yield the former. [This compd. has since been repd. by Schlenk and Bergmann (C. A. 22, 4495).] C. A. R.

Strychnos alkaloids. XLVII. Behavior of derivatives of Hanssen's acid, $\text{C}_{19}\text{H}_{22}\text{O}_6\text{N}_2$, especially on oxidation with bromine and mercuric oxide. HERMANN LEUCHS, CURT BENDER AND WERNER WEGENER (in part with F. KRÖHNKE). Ber. 61B, 2349–58 (1928); cf. C. A. 20, 1811.—The acid $\text{C}_{19}\text{H}_{22}\text{O}_6\text{N}_2$ (I) obtained from cacotheline with Br-HBr had been shown to be converted by further action of the Br-HBr into an acid $\text{C}_{19}\text{H}_{22}\text{O}_8\text{N}_2$ (II), which, unlike I, shows ketone properties. A monoöxime had been repd. and a semicarbazone and its HCl salt are now described. Moreover, it has been found that only a simple oxime and semicarbazone can be obtained. According to the first theory proposed, that the oxidation consists in the conversion of the $>\text{C}:\text{C}<$ group into $>\text{CO}.\text{OC}<$, a diketone would have been expected, and the oxidation therefore probably proceeds according to the 2nd theory, viz., addn. of two HO groups at the $\text{C}:\text{C}$ union reducible with Na-Hg and conversion into $>\text{CO}$ of the group $>\text{CH}(\text{OH})$ assumed but not proven to be present in brucine and cacotheline. The $\text{C}:\text{O}$ group moreover appears to be involved in the reduction with Na-Hg which yields, not very smoothly, up to 60% of a dihydro deriv. $\text{C}_{19}\text{H}_{24}\text{O}_6\text{N}_2$ (III), presumably contg. 3 alc. HO groups, yielding a HBr salt and a nitrate and also, under conditions not definitely established, a hydrate $\text{C}_{19}\text{H}_{26}\text{O}_6\text{N}_2$ (IV) (isolated as the HBr salt). Of the other five O atoms, 1 is probably contained in the $>\text{NCO}$ group and the other 4 in two CO_2H groups, as in I itself, for II also gives a mono- and a di-Me ester, which, however, are weakly basic, the di-Me ester still reacting neutral and only the resin present in abundance in the mother liquors showing an alk. reaction. The ability of I to undergo oxidation without cleavage is not exhausted with the formation of II. With HgO in boiling H_2O II quite smoothly gives up to 77% of a salt $\text{C}_{19}\text{H}_{22}\text{O}_8\text{N}_2$. HBr in which the basicity of the amino acid is so weakened that the salt dissociates almost completely in H_2O . The reaction apparently does not consist in the introduction of an O atom but in a dehydrogenation and the simultaneous addn. of a mol. of H_2O , which the acid amide group is available; in the analogous case of the acid VIII (w), HgO oxidizes it to the compd. $\text{C}_{19}\text{H}_{24}\text{O}_8\text{N}_2$ (VI). Furthermore the oxidizability of HgO must be related with the groups introduced by the 2nd Br oxidation, as HgO is produced neither by I nor by the reduction product, $\text{C}_{19}\text{H}_{24}\text{O}_6\text{N}_2$ (VIII), of I. The action of HgO can therefore consist only in a dehydrogenation of the newly formed alc. groups ketone or to a tautomer of the type of dihydroxymaleic acid, although no products which would support this view could be isolated with ketone reagents. V is also obtained from III.HBr, only in 40% yield, to be sure, but without any greater consumption of HgO than with II. If the assumption is correct that the addn. of HO groups occurs on the $\text{C}:\text{C}$ union of I reducible by Na-Hg , the analogous treatment of II with Br would be expected to result only in dehydrogenation to II, but actually it is obtained in good yield (50%) an acid $\text{C}_{19}\text{H}_{20}\text{O}_8\text{N}_2$ (VIII), apparently along with small quantities of III. There is probably an addn. of H_2O , and the further changes exactly as with I itself: dehydrogenation and addn. of two HO groups which must therefore add at another $\text{C}:\text{C}$ bond than that reducible with amalgam. Both VII and II seem to yield only a mono-Ag salt; that of VII reacts with MeI to form the methyl salt $\text{C}_{19}\text{H}_{24}\text{O}_8\text{N}_2$ (IX), like I itself; to be sure, the IX contained 1 mol. MeOH, 0.5 of which was lost at 130° in vacuo, and the MeOH was therefore probably added chem. The Ag salt of II, on the other hand, gave with MeI only the mono-Me salt. Di-Me ester of II, m. $225-7^\circ$ (decompn.), forms a nitrate; mono-Me ester nitrate. In prisms with 3, the free acid with 2, the HCl salt with $3\text{H}_2\text{O}$. The HBr and salts of IX are described. Dihydrazide of VIII, m. $265-8^\circ$ (decompn.), reacts basic. Salt of VII, prisms with $3\text{H}_2\text{O}$. C. A. R.

Polyhydric alcohol—polybasic acid reaction. I. Glycerol-phthalic anhydride,

R. H. KIENLE AND A. G. HOVEY. General Electric Co. *J. Am. Chem. Soc.* **51**, 509-19 (1929).—The $C_3H_5O_2-C_6H_4(CO)_2O$ reaction proceeds by esterification, since H_2O was the only product collected. No intermediate aldehyde was detected until near gelation. The reaction went very rapidly at the start, evolving heat, and was apparently about half complete within 1 min. As the reaction proceeds under isothermal conditions, the free acidity decreased, the sapon. no. remained fairly const. and the % of esterification increased. The changes in other properties (flow point, viscosity, d , color, n) with time are reported. Similar resinous products result if other polyhydric alcs. or other polybasic acids are used. At whatever temp. the $C_3H_5O_2-C_6H_4(CO)_2O$ reaction is carried out, gelation occurs before the esterification has an opportunity to complete itself.

C. J. WEST

ω -Hydroxyaliphatic acids. Synthesis of sabinic acid. W. H. LYCAN AND ROGER ADAMS. Univ. of Illinois. *J. Am. Chem. Soc.* **51**, 625-9 (1929).—*Mono-Me decane-1,10-dicarboxylate* m. 51.5-2°. *Me 11-aldehydoundecanoate* forms a *semicarbazone*, m. 90-2°. The following ω -hydroxyaliphatic acids were obtained by sapon. of the *Me* esters, which in turn were obtained by reduction of the corresponding *Me* esters of the ω -aldehyde acids, using methods previously described. *9-Hydroxynonanoic acid* (I), m. 53-4°; *Me ester*, b_p 137-9°, n_D 1.4438, d_{20} 0.9588 (*phenylurethan*, m. 53-4°); *10-hydroxydecanoic acid*, m. 75-6°; *Me ester*, b_p 145-7°, n_D 1.4771, d_{20} 0.9618 (*phenylurethan*, m. 54-5°); *11-hydroxyundecanoic acid*, m. 65.6-6°; *Me ester*, b_p 156-9°, n_D 1.4493, d_{20} 0.9542 (*phenylurethan*, m. 64.5-5.5°); *12-hydroxydodecanoic acid* (II), m. 83-4°; *Me ester*, b_p 164-6°, m. 34-5° (*phenylurethan*, m. 64-5°); *13-hydroxytridecanoic acid*, m. 77-8°; *Me ester*, b_p 170-3°, m. 40.5-1.5° (*phenylurethan*, m. 73.5-4°). II is identical with sabinic acid. When I is heated at 3 mm. and 220-30° for 0.5 hr., H_2O is eliminated with the formation of the *compd.* $(C_9H_{16}O_2)_x$, m. 64-6°; warming with 10% aq. KOH for 1 hr. caused complete hydrolysis and acids ppt. I.

Configuration relationship of β -chlorobutyric acid and β -hydroxybutyric acids. P. A. LEVENE AND H. L. HALLER. Rockefeller Inst. *Science* **69**, 47 (1929).—Recent reports on correlation of configurations of HO and halogeno acids by indirect methods are contradictory. Previous evidence warrants the assumption that in simple aliphatic secondary alcs. substitution of OH by halogen proceeds without Walden inversion. Thus, the configuration of halogeno acids can be correlated with carbinols which have already been correlated with lactic acid. The scheme is:

Thus *d*- β -chlorobutyric acid is correlated with *l*- β -hydroxybutyric acid and hence with *l*-lactic acid.

ALBERT P. SACHS

The specificity of erepsin and trypsin kinase. The behavior of these enzyme complexes toward polypeptides and compounds containing both α -amino acids and β -aminobutyric acid. The action of *N* alkali on these compounds. EMIL ABDERHALDEN AND RICHARD FLEISCHMANN. Univ. Halle. *Fermentforschung* **10**, 195-212 (1928).—A no. of new peptide derivs. were prepd. for a study particularly of the effect of addn. of PhNCO to the NH_2 group and of the influence of an amino acid with NH_2 in other than the α -position on their susceptibility to enzymic cleavage. The following were obtained from the appropriate peptide and isocyanate: *di[phenylisocyanate-d-valyl-d-alanyl]-l-cystine*, decomp. above 175°, yield 80%; *di[phenylisocyanate-l-leucylglycyl]-l-cystine*, decomp. 190°, yield 75%; *phenylisocyanate-diglycylglycine*, m. 214-6°, 85% yield; *α -naphthylisocyanate-diglycylglycine*, decomp. 238°, yield 75%; *phenylisocyanate-triglycylglycine*, gradual decompn. above 220°, yield 80%; *phenylisocyanate-tetraglycylglycine*, decomp. above 220°. Tetraglycylglycine was condensed with *d*- $Me_2CHCH_2CHBrCOCl$ to form *d*- α -bromoisocaproyltetraglycylglycine, decomp. above 220°, $[\alpha]_D^{20}$ 12.21°, and this was aminated by 25% NH_4OH to *l*-leucyltetraglycylglycine, decomp. above 222°, $[\alpha]_D^{20}$ 9.41°. New derivs. of $MeCH(NH_2)CH_2CO_2H$

prepd. by customary procedures were *phenylisocyanate-dl-leucyl-β-aminobutyric acid*, m. 188°, yield 70%; *benzoyl-dl-leucyl-β-aminobutyric acid*, m. 182°, yield 75%; *dl-α-bromoisocaproyl-dl-leucyl-β-aminobutyric acid*, m. 172°, yield 80%; *dl-leucyl-dl-leucyl-β-aminobutyric acid*, m. 141°, yield 40%; *PhNCO deriv.* of the preceding, m. 212°. *β-Chlorobutyryl chloride* (I), b_{40} 65–7°, was obtained in 90% yield by refluxing 40 g. $\text{MeCHClCH}_2\text{CO}_2\text{H}$ with 80 g. SOCl_2 4 hrs. at 60°. This was condensed with *dl-leucine* to yield *β-chlorobutyryl-dl-leucine*, m. 132°, and the latter aminated to 30% *β-aminobutyryl-dl-leucine*, m. 265–8° (decompn.). Condensation of I with glycine gave 70% *β-chlorobutyryl-glycine*, m. 199°, which was aminated to 30% *β-aminobutyryl-glycine*, m. 227°.

β-aminobutyryl-triglycylglycine, m. 227°, was obtained from the tetrapeptide and I, and aminated to *β-aminobutyryl-triglycylglycine*, decomp. 249°. Other derivs. prepd. in a similar manner were *β-chlorobutyryl-β-aminobutyric acid*, m. 142°; *β-aminobutyryl-β-aminobutyric acid*, m. 232°; *β-chlorobutyryl-l-leucyltetraglycylglycine*, decomp. above 215°; *β-aminobutyryl-l-leucyltetraglycylglycine*, decomp. above 223°. The *PhNCO* and $\alpha\text{-C}_{10}\text{H}_7\text{NCO}$ derivs. described above are all hydrolyzed by *N* NaOH at 37°, those with *PhNCO* attached to glycine yielding phenylisocyanateglycine as one of the cleavage products. Both *PhNCO* derivs. contg. cystine are hydrolyzed by trypsin-kinase but not by erepsin. Of the other *PhNCO* polypeptides none was attacked by erepsin, and only the tetraglycylglycine deriv. by trypsin-kinase. The hexapeptide is 80% hydrolyzed by *N* alkali into its individual components in 3 hrs., trypsin-kinase effects considerable cleavage, while erepsin is without action. *dl-Leucyl-β-aminobutyric acid* is resistant to *N* alkali for 125 hrs., while its *PhNCO* deriv. undergoes 100% hydrolysis in 20 hrs., but its *Bz* deriv. is not attacked. The dipeptide *β-aminobutyryl-glycine* is resistant, but the tetra-, penta- and heptapeptides with terminal glycine and *β-aminobutyryl* are hydrolyzed. *β-Aminobutyryl-β-aminobutyric acid* is not attacked. None of the peptides contg. *β-aminobutyric acid*, either as a terminal acyl or as a terminal acid, is attacked by erepsin. The same is true with respect to trypsin-kinase with the exception of *β-aminobutyryl-l-leucyltetraglycylglycine* which gave in 22 hrs. a hydrolysis corresponding to 51% of 1 CONH linkage. This observation bears out the theory that tryptic action is dependent upon a free CO_2H which must not be present in a foreign component such as a β -amino acid. A. W. DOX

The influence of substitution in the free amino group of polypeptides by groups of definite character, and their cleavage by *N* alkali, erepsin and trypsin-kinase. EMN. ANDERHALDEN, ERMBRECHT RINDTORFF AND ADOLF SCHMITZ. Univ. Halle. *Fermentforschung* 10, 213–32(1928).—Substitution of a no. of radicals in the NH_2 group of peptides was made for the purpose of detg. their influence on peptide cleavage by alkali and enzymes. *Phthalyl-dl-leucylglycine*, m. 119–20°, previously prepd. by Brigl and Klenk (*C. A.* 18, 2501) in an amorphous state, was obtained cryst. *Trichloroacetyl-dl-leucylglycine*, m. 172–3°, was obtained in 70% yield from Cl_3CCOCl and the dipeptide. *Methyl-dl-leucylglycine*, m. 225°, was prepd. in 60% yield from *dl-α-bromoisocaproylglycine* and aq. MeNH_2 and *methyl-diglycylglycine*, m. 139–40°, from chloroacetyldiglycylglycine and MeNH_2 . *Et* glutamate-HCl was condensed with $(\text{COCl})_2$ by refluxing in C_6H_6 soln. until evolution of HCl ceased, yielding 80% *oxalyl-di[ethyl-d-glutamate]*, m. 94°, and with $(\text{CH}_3\text{COCl})_2$ by the same procedure yielding 60% *Et α-succinimidoglutarate*, a non-crystg. oil. Derivs. obtained from *glycyl-dl-leucine* by simple condensations were: *β-naphthalenesulfonyl deriv.*, m. 123° (50%); *PhNCO deriv.*, m. 177° (90%); $\text{ClC}_6\text{H}_4\text{CO deriv.}$, m. 190° (80%); *butyryl deriv.*, m. 182° (60%). *Oxalyl-di[glycyl-dl-leucine Et ester]*, m. 163°, was obtained in 50% yield by boiling the dipeptide ester-HCl salt with $(\text{COCl})_2$ in C_6H_6 . *Chloroacetyl-dl-valine*, m. 129.5–30.5°, was prepd. in 60% yield from *dl-valine* and ClCH_2COCl , and aminated by treatment with 25% NH_4OH to 67% *glycyl-dl-valine*, m. 240°; *PhNCO deriv.*, m. 155° (68%); $(\text{CH}_3\text{CHCO deriv.})$, m. 151.5–2.0° (88%); *Bz deriv.*, m. 135–6° (36%). *Dichloroacetyl-glycine*, m. 125–6°, was obtained in 81% yield from glycine and Cl_2CHCOCl . *N* alkali at 37° attacks *dl-leucylglycine* more readily than its phthalyl deriv., whereas the *Me* deriv. is almost totally resistant. The Cl_3CCO deriv. splits off $\text{Cl}_3\text{CCO}_2\text{H}$ which makes a detn. of peptide cleavage impossible. Substitution of a *Me* group in diglycylglycine causes some inhibition of cleavage but to a less extent than in the dipeptide. Erepsin does not attack any of the *dl-leucylglycine* derivs. nor the *Me* tripeptide. Trypsin-kinase hydrolyzes them all with the exception of the *Me* deriv. The oxalyl deriv. of glutamic acid is rapidly hydrolyzed by *N* alkali with liberation of $\text{C}_2\text{O}_4\text{H}_2$, while the succinyl deriv. is quite resistant. Neither one is attacked by erepsin, and only the oxalyl deriv. by trypsin-kinase but without liberation of $\text{C}_2\text{O}_4\text{H}_2$. All

of the glycyl-*dl*-leucine derivs. are hydrolyzed by *N* alkali, the PhNCO deriv. most rapidly and the β -C₁₀H₇SO₂ deriv. with extreme slowness. All are hydrolyzed by trypsin-kinase, and none by erepsin. The glycyl-*dl*-valine derivs. are less resistant to alkali than the dipeptide itself. The Cl₂CHCO deriv. first splits off Cl₂CHCO₂H then the residual dipeptide undergoes hydrolysis at its usual rate. The PhNCO deriv. is attacked by trypsin-kinase but not by erepsin. The results obtained with these substitutions support the previously expressed view that the point of attack by the free NH₂ group of polypeptides, while substitution in the NH₂ facilitates may be noted. The trypsin-kinase. With the exception of the Me group, a variety of foreign radicals into the same influence although qual. differences in rate of hydrolysis by trypsin-kinase. The observation is that the introduction of polypeptide group facilitates the breakdown of polypeptide.

Cleavage of diethyl α,α' -dibromodipropionate by secondary amines.

FUSON and RAYMOND L. BRADLEY. Univ. of Illinois. *J. Am. Chem. Soc.* 51, 599-60 (1929).—(CH₃CHBrCO₂Et)₂ is cleaved by piperidine to give 75% of Et β -piperidinopropionate, b₂₂ 114-6°, d₄₀ 0.927, whose methiodide m. 100-2°. Similarly, Pr₂N gives Et β -dipropylaminopropionate, b₂₀ 112-4°; methiodide m. 76°. C. J. WEST

Naphthenic acids. VIII. Polymethylene rings of naphthenic acids in Japanese petroleum.

TSUTOMU KUWATA. *J. Faculty Eng. Tokyo Univ.* 17, 305 (1928); cf. C. A. 19, 486.—Naphthenic acid (I), b₁ 133-70°, d₄²⁰ 0.9629, n_D²⁰ 1.4602, neutralization no. 297.1, was used and corresponds to a mixt. of the 22nd and 24th. I was heated with 1 mol. PCl₅, the POCl₃ removed by distn., dissolved in 1 mol. PhOH and K₂CO₃, heated for 0.5 hr. on the water bath, washed with H₂O, dried with CaCl₂, the PhH removed by distn., the residue was distilled and gave 90% Ph naphthenate (II), a colorless, viscous oil. When II and abs. EtOH in a closed flask with reflux condenser and stirrer were treated with 18 atoms Na, warmed after most of the Na had been added, H₂O added, the removed by distn., the residue extd. with Et₂O, the ext. distd. in vacuo, it gave naphthene alc. (III), a colorless, viscous oil, b₁ 100-33°, d₄²⁰ 0.8953, n_D²⁰ 1.4592.

III (naphthene iodide (prepd. by heating III with 3 mols. I₂ and 1 mol. red P) was reduced by boiling with Zn-Hg in EtOH and gave 70% naphthene hydrocarbon which was purified by washing with H₂SO₄, aq. KOH and distd. over Na; it b. 160-92°, d₄²⁰ 0.791, 1.4336, 85.45% C, 15.04% H, and has an odor of purified petroleum; treatment with Pt black at 290-300° by Zelinskii's method (cf. C. A. 17, 3124) had no effect; concluded that the original acid contains no homologs of hexamethylenecarboxylic acid and that the acids are probably pentamethylenecarboxylic. In a similar manner the following were prepd. from the naphthenic acid derived from Kurokawa petroleum: naphthenic acid, b₁ 168-98°, d₄²⁰ 0.9942, n_D²⁰ 1.4744, neutralization number 160 responding to a C₁₄ acid; naphthene alc., b₁ 126-55°, d₄²⁰ 0.9270, n_D²⁰ 1.4756; naphthene hydrocarbon, b. 203-43°, d₄²⁰ 0.8425, n_D²⁰ 1.4548, 85.66% C, 13.67% H; treatment by the Zelinskii method gave a product of which 6.5% was sol. in 95% EtOH having a higher d. and n; from this it is concluded that the Kurokawa naphthenic acids with d. > 0.99, though in a very small amount, contain the homologs of hexamethylenecarboxylic acid. IX. Chemical constitution of octonaphthenic acid derived from Nishiyama petroleum.

Ibid 311-7.—Nearly pure octonaphthenic acid, C₂₄H₄₀O₂ (IV), was isolated from pure mixed naphthenic acids derived from Nishiyama petroleum distillate by repeated fractional distn. of the acids and their Me esters; it m. 81.5°, b. 231.5-7.5°, d₄²⁰ 0.9417, n_D²⁰ 1.4318, and is either a stereo- or chem. isomer of that reported by Aschan (cf. Ber. 23, 867(1890)); when 11 g. IV and 0.9 g. red P in a flask with reflux condenser was treated with 12 cc. Br₂, warmed for 6 hrs., the condenser removed, excess Br₂ evapd., poured into MeOH, extd. with Et₂O, the ext. washed with H₂O, then with dil. Na₂CO₃, dried over Na₂SO₄, the Et₂O removed and distilled in vacuo, 11 g. of Me α -bromooctonaphthenate, C₂₄H₃₉BrCO₂Me (V), was obtained, 95-105°, d₄²⁰ 1.249, n_D²⁰ 1.4612. V (8.6 g.) and 330 cc. 2% aq. KOH were heated at 60-70° for 10 hrs., cooled, acidified with H₂SO₄, extd. with Et₂O and the Et₂O evaporated, the viscous residue (5.5 g.) is α -hydroxyoctonaphthenic acid, C₂₄H₄₀O₃, d₄²⁰ 1.023, 1.4518, decompd. on warming with H₂SO₄ with evolution of CO; when 3.8 g. is heated with 6 g. PbO₂ and a few drops of H₃PO₄, then distd. with steam, a compd. with aldehyde properties is obtained which is oxidized by alk. KMnO₄ to an acid m. 80-110° gives the CHI₃ test, and forms a semicarbazone, m. 89-90°. The results indicate the

V is a homolog of methylpentamethylenecarboxylic acid having no tertiary carbon atom at the α -position.

Transformations of β -pentabenzoyl-*h*-glucose. HANS H. SCHLUBACH, FRIEDRICH TREFZ AND WOLFGANG RAUCHENBERGER. Univ. Hamburg. *Ber.* 61B, 2368-71 (1928).—The end Bz group in β -pentabenzoyl-*h*-glucose (I) is rapidly replaced by HCl and HBr but the resulting halogenoses lose their halogen with extraordinary ease and change into *tetrabenzoyl-*h*-glucose* (II) (cf. Ohle and his co-workers, *C. A.* 23, 102), the Cl considerably less easily than the Br compd. As far as can be judged from the rotations of these labile compds. there is formed an equil. mixt. of the 2 possible stereoisomeric halogenoses and not 1 of the stereoisomers almost exclusively. A method similar to that of O. and his colleagues, which permits of working up the reaction product without the use of H_2O , is described. The II, most simply obtained by shaking the halogenoses with Ag_2CO_3 in moist Me_2CO , cannot be made to crystallize and its structure was established by converting it back into I. With Ag_2O and MeI II gives a *tetrabenzoyl-*h*-methylglucoside* (III) which, from its rotation, seems to be a β -deriv., are those obtained from the tetraacyl-*n*-glucoses. On the other hand, when III and the *n*-isomer (IV) are treated under the same conditions with NH_3 in MeOH, smoothly yields the β -*n*-methylglucoside, whereas III undergoes both sapon. and isomerization, for the rotation of the product (V) is much higher, $[\alpha]_D^{20} -16.4^\circ$ (H_2O , 1.07), than would be expected for the *h*-glucoside (about -60°). Permethylation of the V with Ag_2O and MeI and conversion into the reducing tetramethylglucose gives a product with an equil. value $[\alpha]_D^{20}$ of -27.5° (CHCl_3), showing that V is merely a mixture of the α - and β -*h*-glucosides and that in its formation there has not been a partial arrangement into the *n*-glucoside after the sapon. NH_3 in MeOH thus effects in the series an isomerization which in the *n*-series has hitherto been observed only with

Since if any of the unstable free *h*-glucose had been formed it would undoubtedly at least, have rearranged into the *n*-glucose, the above observation indicates the stereoisomeric rearrangement occurs without any preliminary splitting off of the Me group. From 5 g. I kept 20 hrs. at 20° with 15 cc. of dry liquid HCl is obtained a sirup with 4.01-4.49% Cl and $[\alpha]_D^{20} -10.5^\circ$, -11.3° (CHCl_3 , c 1.138, 1.060).

With either liquid HBr or HBr in AcOH are obtained products with rotations to 31° and Br contents much lower than that calcd. for a halogenose. II (11.5 g. 15 g. I and HBr in AcOH at 15° , the mixt. then being treated with ice H_2O and product shaken in Me_2CO with Ag_2CO_3), $[\alpha]_D^{20}$ $5.15^\circ \rightarrow 4.96^\circ$ (CHCl_3 , c 1.088) (96% alc., c 1.0112). III, contains 1 mol. MeOH, $[\alpha]_D^{20} -48.6^\circ$ (CHCl_3 , c 1.0112).

C. A. R.

Structure of β -glucochloralose. H. W. COLES, L. D. GOODHUE AND R. M. HIXON. College. *J. Am. Chem. Soc.* 51, 519-24(1929).— $\text{Cl}_3\text{CCHO} \cdot \text{H}_2\text{O}$ (300 g.), concd. H_2SO_4 and 200 g. glucose at $12-15^\circ$ give 60 g. β -glucochloralose (I) and of about equal parts of 2 dichloralglucoses, m. 225° (II) and 135° ; at times a dimer, m. 188° , is isolated. Reaction of I with $\text{Cl}_3\text{CCHO} \cdot \text{H}_2\text{O}$ and H_2SO_4 gives a 1st isomer, m. 128° ; the 2 Ac derivs. m. 126° and 198° , resp. of II and a 2nd isomer, m. 268° ; the 2 Ac derivs. m. 126° and 198° , resp. and Payne, *C. A.* 17, 3862). I and Me_2SO_4 with solid NaOH give the *tri-Me* in 100-10%; a 4th group could not be introduced. Reduction with Al-Hg and HCl gives *trimethylglucose dichloroacetaldehyde*, m. 68° ; reduction with Na-Hg gives a *mono-Cl* deriv., b. $155-60^\circ$. 3,5,6-Trimethylglucose and $\text{Cl}_3\text{CCHO} \cdot \text{H}_2\text{O}$ in H_2SO_4 give 3,5,6-trimethylmonochloralglucose, m. 120° , $[\alpha]_D^{20} -29.01$ (0.8413 g. 398 cc. CHCl_3); this does not react with MeMgI. The present formulas for I do not explain the formation of the dichloralglucoses; the reaction reported by Hanriot and Kling by which both the aldehyde and glucose are identified would indicate an ether rather than a C-C linkage.

C. J. WEST

Some derivatives of the benzylidenemethylglucosides. HEINZ OHLE AND KURT BER. Univ. Berlin. *Ber.* 61B, 2387-92(1928).—It was shown (*C. A.* 23, 103) that the stability of the O bridge in derivs. of monoacetoneglucose can be greatly increased by appropriate esterification. The structure of the mother substance is the only partially acylated derivs. which can be obtained are those in which the characteristic acid groups are in position 3, 5 or 6. In order to be able to determine the influence of esterification of the 2-HO group the study of the benzal derivs. (I) and β -Me glucoside was undertaken but although this study has not progressed beyond the initial stage the results so far obtained are published now because these

compds. have become of importance in the synthesis of disaccharides (Freudenberg, Toepffer and Andersen, *C. A.* 23, 107). These investigators have shown that in the I the 3-HO group is not combined with the PhCH residue. Of the 3 remaining possibilities (4,6-, 5,6- and 2,4-derivs.), the last is rendered very improbable by the observations of Irvine (*J. Chem. Soc.* 103, 575(1913)) and also because (1) levoglucosan does not condense with BzH and (2) the velocities of esterification of the 2 free HO groups in the I are almost equal and it is a general rule that in glucose derivs. a primary carbinol grouping is more readily esterified than a secondary grouping. If the I were 5,6-derivs. they should be closely related to diacetoneglucose (II) and easily transformable into it or the analogous isopropylidenemethylglucoside (III). To avoid drawing possibly false conclusions from their results, O. and S. first studied the action of the Me glucosides (IV) with Me_2CO . As was to be expected, the IV did not react any more than glucose with Me_2CO in the presence of CuSO_4 ; II was formed only with mineral acids as catalysts. The two IV differ materially in their reactivity; the α -IV shows a detectable transformation into II only with more than 2 cc. concd. H_2SO_4 per 100 cc. Me_2CO , while the β -IV forms II with 0.5 as much acid. Furthermore, by following polarimetrically the changes which occur in solns. of II in Me_2CO with H_2SO_4 , it was found that with 1 or 2 cc. concd. acid per 100 cc. Me_2CO there is no appreciable change in rotation in 5 hrs.; only mono- and diacetoneglucose could be isolated and the weak reducing power showed that only traces of free glucose are formed, *i. e.*, under such conditions the furoid structure of glucose is perfectly stable. α -I under the same conditions would therefore be expected to change, in part at least, into II or the hypothetical III if it were a 5,6-deriv. whereas this reaction would be impossible if it is a 4,6-deriv. because the pyroid α -IV is unchanged under such conditions. The exptl. results are in favor of the 4,6-structure; α -I in 100 cc. Me_2CO with 2.8 cc. concd. H_2SO_4 begins to deposit α -IV in a few min. and is almost quant. decompd. into α -IV and BzH, no II or III is formed. For the tetraacetates of the Me lactolides of the hexoses Hudson obtained the value 53,500 for $2A_M (= M_\alpha - M_\beta)$. For the dibenzoates of the I, O. and S. find 39,750, for the di-*p*-toluenesulfonates 71,500. This is another illustration of the fact that A_M is not const. but is largely influenced by the structure of the rest of the sugar mol. In this particular case, to be sure, the condensation of BzH with α -IV gives 2 isomers (*cis* and *trans*) because the C atom of the PhCH group becomes asym., and the same is of course true for β -IV. It is conceivable that in the 1 case the *cis*-form, in the other the *trans*-form is the chief product, and the esters of the I could not therefore be expected to give the same value for A_M as the tetraacetates of the IV, for in the Hudson formula, $M = A + B$, B would not be identical in the 2 derivs. of I, as it would represent the rotation of the *cis*-form in the 1 case, that of the *trans*-form in the other. But if the mols. of the I derivs. be imagined as split up into 3 parts, as shown in the accompanying formula, with abs. rotation values of A, B and C, then by the principle of optical superposition M_α should be $A_M + B$

+ C and M_β should be $-A_M + B - C$, or $M_\alpha - M_\beta = 2(A_M + C)$; as this formula does not contain B, $M_\alpha - M_\beta$ should be const. for the 2 pairs of esters if Hudson's principle held good. 2,3-Dibenzoyl-4,6-benzylidene- α -methylglucoside (4.5 g. from 5 g. α -I in $\text{C}_6\text{H}_5\text{N}$ with BzCl in CHCl_3 at 38°), m. 148° , $[\alpha]_D^{19}$ 96.89° (CHCl_3 , c 2.828); β -isomer (1.2 g. from 1 g. I), m. 185° , $[\alpha]_D^{19}$ 15.84° (CHCl_3 , c 2.840). 2,3-Di-*p*-toluenesulfonate of α -I (4.2 g. from 3 g. I), m. 149° , $[\alpha]_D^{19}$ 66.5° (CHCl_3 , c 3.068; β -isomer, m. 158° , $[\alpha]_D^{19}$ -54.70° (CHCl_3 , c 2.796).

C. A. R.
Mutarotation of galactose. THOMAS M. LOWRY AND GILBERT F. SMITH. Cam-

bridge Univ. *J. Phys. Chem.* 33, 9-21(1929).—Exptl. mutarotation curves for α - and β -galactose can be represented as the sum of 2 exponential curves, one a simple unimol. curve of long period, the other a unimol. curve of short period (cf. Worley and Andrews, *C. A.* 22, 1332), i. e., $\theta_\alpha = A_1e^{-m_1t} + B_1e^{-m_2t} + C$. If the improbable assumption is made that only 3 sugars are present at equil. we have at 20° $\alpha:\mu:\beta = 28.5:12.0:-59.5$; at 0.8° $\alpha:\mu:\beta = 30.0:5.5:64.6$. Soly. detns. give an uncor. value of 37% α at 0° in contrast to 6.6% by Riiber and Minsaas (cf. *C. A.* 21, 697). A. P. S.

Preparation of triacetylstarch and its molecular weight. YOJIRO TSUZUKI. Univ. Tokyo. *Bull. Chem. Soc. Japan* 3, 276-85(1928).—A new method is described for starch acetylation, which had the advantages of being more rapid than any other, and avoiding partial depolymerization. Forty g. starch is mixed with 50 g. $ZnCl_2$ in 23 g. H_2O to a transparent sticky paste and heated on the water bath; 220 cc. Ac_2O is gradually added, a part of which is converted into $AcOH$ by the H_2O present, which acts as a solvent for the Ac deriv. The temp. is not allowed to rise higher than 70° during the mixing and is kept at this temp. for 0.5 hr. Small lumps of unchanged starch are centrifuged, the $AcOH$ partially evapd. and the remaining liquid poured into ice water. The acetylated product seps. out as a flocky ppt. By repeated H_2O washings, a fine powder is obtained. The yield is 60 g. of dry substance, i. e., 90%. Purification is obtained by alc. pptn. from hot $CHCl_3$. The acetylated deriv. differs from any one previously described. It sinters 258° and slowly decomp. 270°, dissolves in $AcOH$, $CHCl_3$ (free from alc.), pyridine, Ac_2O , concd. H_2SO_4 (remaining undecompd. for 20 min.), $C_2H_4Br_2$, $CHBr_3$, $PhOH$, far more readily at higher temp. The solns. are turbid over 5%. It is a little sol. in Me_2CO , $EtOAc$, $MePh$, less in C_6H_6 , CCl_4 , far less in petroleum ether, Et_2O , alcs., and almost insol. in H_2O . Dissolved in hot $MePh$ and allowed to cool, it gives a strong fluorescence. Its optical properties are: $[\alpha]_D^{25} 170.2^\circ$ (in $CHCl_3$) and 160.4° (in $AcOH$), $[\alpha]_D^{14} 159.6^\circ$ in pyridine. Sapon. with $NaONa$ is instantaneous. The sapon. product is sol. in H_2O . The mol. wt. of the Ac deriv. has been detd. by cryoscopy *in vacuo* and by ebullioscopy. The approx. results were: cryoscopy: 5-6000 in $C_2H_4Br_2$, 5000 in $CHBr_3$, 2000 in camphor, 200, 2000 and 6000 in $AcOH$, ∞ in $PhOH$; ebullioscopy: 5-7000 in $AcOH$, 6-7000 in $CHCl_3$, ∞ in Me_2CO . ALBERT L. HENNE

Synthesis of the basic substance of inulin. HANS H. SCHLUBACH AND HORST ELSNER. Univ. Hamburg. *Ber.* 61B, 2358-63(1928).—Irvine and Garrett (*C. A.* 5, 1077) obtained from fructose and Me_2CO contg. HCl , together with α -diacetonefructose, large quantities of a sirup which they considered to be a mixt. of α - and β -2,3-monoacetonefructoses. S. and E. have improved the method of prepn. by carrying out the after-acetonization with anhyd. $CuSO_4$ instead of HCl , to avoid the rearranging influence of the latter, and by drying the Et_2O -insol. residue in a high vacuum, taking it up in alc. and pptg. it by pouring the soln. into Et_2O . The substance was in this way obtained as a solid, although amorphous, powder. The varying yields led to the suspicion that the course of the reaction depends on the H_2O content of the Me_2CO and systematic expts. showed that with 0.05% H_2O α -diacetonefructose is formed almost exclusively, while with 2% H_2O a max. of the new product is obtained. Detn. of the Me_2CO by the Elsner method (see following abstr.) led to the surprising result that the substance contained only about 0.1 the quantity of Me_2CO calcd. for a monoacetonefructose, and by systematic reppnts. controlled by quant. detns. this small quantity of Me_2CO was completely gotten rid of. The Me_2CO -free material showed, contrary to the observations of I. and G., a distinct reducing power even after treatment with yeast, and by means of abs. alc. was sepd. into 2 components: extremely hygroscopic, white, alc.-sol. powder (I), with the compn. and mol. wt. of a fructose anhydride, and an alc.-insol., only little hygroscopic powder (II), with the compn. and mol. wt. of a difructose. Because of the small yield and difficulty of purifying it, II could not be characterized with abs. certainty. On permethylation, I gave a hexamethyldifructose anhydride, $b_p 150^\circ$, $n_D^{14} 1.4738$, $[\alpha]_D^{20} 31.1^\circ$ ($CHCl_3$, c 1.13), which on hydrolysis yielded a trimethylfructose giving with $PhNHNH_2$ an osazone identical with that of the trimethylfructose (III) obtained by Haworth and Learner from trimethylinulin. They proved III to be a 3,4,6-trimethylfructose<2,5> and concluded that the basic substance of inulin is a 1,2-fructoseanhydride<2,5> or a 1',2,1',2'-difructose anhydride<2,5> (IV). Inulin may be built up from such a basic substance in 2 ways: by a chain-like addn. of fructose mols. to each other through a primary valence, the reducing HO group of 1 mol. combining with 1st HO group of the next, or the I condenses through II to IV which then, under the influence of supermol. forces, associates to inulin. S. and E. believe the latter view better accords with the exptl. evidence now available. II or IV is formed

with the greatest ease from I. Thus, with alk. Me_2SO_4 I gives not a trace of monomol. condensation product but only the Me deriv. of IV which on further treatment yields highly polymerized products. The same phenomenon occurs on acetylation. Although the rotations of these synthetic products do not always agree with those of the natural substances it must be remembered that in the formation of IV there are 3 stereochem. possibilities; the 2 residues may combine at the α,α -, β,β - or α,β -positions; for natural inulin the union is supposed to be at the β,β -position. Numerous reports in the older literature make it probable that IV occurs primarily, and quite frequently, in nature, and on aging polymerizes to the insol. inulin. I, sinters $55-60^\circ$, effervesces $86-8^\circ$, $[\alpha]_D^{18} -8.9^\circ$ (H_2O , c 1.46), -6.9° (EtOH , c 1.16), mol. wt. in H_2O 170, has 14% the reducing power of fructose, gives a strong Selivanov reaction, turns brown with KOH, slowly decolorizes KMnO_4 , is rapidly hydrolyzed, with partial decompn., by 0.5% HCl at 100° to a strongly *l*-rotatory substance, is not fermented by yeast but is attacked by molds. II, decomp. 198° , $[\alpha]_D^{18} -25.5^\circ$ (H_2O , c 1.06), mol. wt. in H_2O 373, has 24% the reducing power of fructose but this disappears after heating 1 hr. with *N* NaOH.

C. A. R.

Method for the determination of acetone groups in acetone sugars. HORST ELSNER. Univ. Hamburg. *Ber.* 61B, 2364-7(1928).—The Me_2CO detn. can be made smoothly and with certainty, with a max. error of $\pm 0.5\%$, by quantitatively splitting and distg. off the Me_2CO and detg. it in the distillate by the Messinger method while at the same time a parallel detn. is run under the same conditions on a soln. of known concn. approx. equal to that of the unknown, the Me_2CO in the latter then being calcd. from the ratio of I consumed by the 2 solns. Special expts. showed that the results obtained by the M. method are greatly influenced by the length of reaction, the temp., the concn. of the Me_2CO and KOH and the excess of H_2SO_4 used. The Me_2CO is quant. split and distd. off by weighing 50-100 mg. of the acetone sugar into a Claisen flask, the side neck of which carries a dropping funnel and is connected through a short Liebig condenser with a 100 cc. measuring flask in ice. Through the dropping funnel are added 4 cc. concd. H_2SO_4 and 30 cc. H_2O and an additional 80 cc. H_2O is added as the liquid dists. over. Rubber stoppers must be used, as corks after a short time give off substances which react with the hypoiodite. The distillate is dild. to the 100 cc. mark and at the same time a soln. of known Me_2CO concn. is prepd. either from specially distd. Me_2CO according to Goodwin or from a distillate prepd. as above from a pure acetone sugar, such as β -diacetonefructose. The 2 solns., after addn. of 30 cc. *N* KOH, are allowed to stand about 1.5 hrs. until they have reached the same temp., then treated with vigorous shaking with the same quantities of 0.1 *N* I (about 40 cc.), acidified after exactly 4 min. with about 35 cc. *N* H_2SO_4 and titrated back with 0.1 *N* $\text{Na}_2\text{S}_2\text{O}_3$.

C. A. R.

Ring cleavages in the cyclopropane series. XIV. R. STOERMER AND FR. SCHENCK, WITH H. BUSCHMANN. Univ. Rostock. *Ber.* 61B, 2312-23(1928); cf. *C. A.* 22, 1142-. It had been shown that a series of truxill- and truxinamic acids can be converted, by degradation of the corresponding amino acids with NOBr, into structurally identical 3-benzoyl-2-phenylcyclopropane-1-carboxylic acids (benzoyl = $\text{PhCH}(\text{OH})$) which can theoretically exist in the 8 *dl*-forms, Ia and b, IIa and b, IIIa and b and IVa and b. Of these 5 were isolated and by oxidation of the PhCHOH group to PhCO were obtained the 4 corresponding Bz acids (V, VI, VII and VIII), 2 of which (VI and VII) had already been obtained by Kohler, Conant and Steele in an entirely different way. They had found that the ring in their acids is ruptured with extraordinary ease by various reagents and ascribed this reactivity to the Bz group. R. and S. had also observed this easy cleavage with V, VII and VIII and it is shown in the present paper for VI by its catalytic reduction to $\text{PhCH}_2\text{CH}(\text{CH}_2\text{Bz})\text{CO}_2\text{H}$ (cleavage between C atoms 2 and 3). But the PhCHOH derivs. I-IV also undergo cleavage, not on catalytic reduction, to be sure, but with strong mineral acids, as HCl or H_2SO_4 , the latter in the presence of AcOH or HCO_2H . Some of these cleavages with Br and HBr had already been described. It has now been found that IIb adds HCl to form α -chlorobenzyl- β -benzalpropionic acid (IX) in which the Cl can readily be replaced by H by means of Al-Hg, the formation of $\text{PhCH:CHCH}(\text{CH}_2\text{Ph})\text{CO}_2\text{H}$ showing that the HCl adds exactly like HBr to the 2- and 3-C atoms of the ring, a conclusion confirmed by the reconversion of IX into IIb with Na_2CO_3 or NaOH. Whether H_2O is first split off and the ring is then ruptured by the HCl, or *vice versa*, has not been established with certainty. Furthermore IX splits off Cl and CO_2 with Na_2CO_3 , forming $(\text{PhCH:CH})_2$, and also decomp. into BzH and $\text{PhCH:CHCH}_2\text{CO}_2\text{H}$. With H_2SO_4 -AcOH, the PhCHOH acids give the compd. $\text{PhCH:CHCH}(\text{CO}_2\text{H})\text{CH}(\text{OAc})\text{Ph}$ (X).

which, since it contains 2 asym. C atoms, can theoretically exist in 2 *dl*-forms and each of these in turn can exist in 2 *cis-trans* forms. As a matter of fact **IIa**, **IIb** and **IIIa** give an acid (**XI**), m. 152–3° (*Me ester*, m. 87°), and **Ia** an isomeric acid (**XII**), m. 152–4° (*Me ester*, m. 92–2.5°); the *Me ester* of **Ia** gives the esters of both **XI** and **XII**. The same is true of the addn. of HCO_2H . The difference between **XI** and **XII** is due to the position of the groups around the asym. C atoms for on catalytic reduction and subsequent sapon. there are formed 2 different α -benzoxyl- γ -phenylbutyric acids (**XIII** and **XIV**). That the cleavage of the ring occurs between C atoms 2 and 3 is shown by the formation of $(\text{PhCH}:\text{CH})_2$ from **X** with $\text{AcOH} \cdot \text{H}_2\text{O} \cdot \text{H}_2\text{SO}_4$; furthermore, sapon. of the *Me esters* with alc. KOH gives $\text{PhCH}:\text{CHC}(\text{:CHPh})\text{CO}_2\text{H}$. The position of the OAc group is detd. by the peculiar decompn. of the **X** into $\text{PhCH}:\text{CHCH}_2\text{CO}_2\text{H}$, BzH and AcOH on boiling with Na_2CO_3 , a decompn. to be ascribed primarily to the double bond, as it no longer takes place after hydrogenation (the esters of **X**, the formyl analog (**XVII**, below) and **IX**, on the other hand, decomp. into $\text{PhCH}:\text{CCH}(\text{:CHPh})\text{CO}_2\text{H}$). The *Me esters* of **XIII** and **XIV** are oxidized to the same *Me* α -benzoxyl- γ -phenylbutyrate (**XV**), a result made possible only by destroying the asymmetry of the C atom carrying the HO group. When **XV** is sapond. the resulting acid at once decomp. into CO_2 and 1,4-diphenyl-1-butanone (**XVI**), identical with a product obtained from $\text{PhCH}_2\text{CH}_2\text{CH}_2\text{MgBr}$ and BzH and subsequent oxidation. The identity of the oily **XV** obtained from **XIII** and **XIV** was established by their conversion with $\text{H}_2\text{NCONHNH}_2$ into 3-phenyl-4-[β -phenylethyl]-5-pyrazolone-1-carboxamide (**XVII**). With HCO_2H , **IIa** and **IIb** give a compd. **XVIII** (**X** with OCH instead of OAc), m. 160° (*Me ester*, m. 96°), while the *Me ester* of **Ia** gives chiefly an isomeric ester (**XIX**), m. 93–4°. In attempting to establish the structural identity of **XIII** and **XIV** by splitting off H_2O to give $\text{PhCH}_2\text{CH}_2\text{C}(\text{CO}_2\text{H})\text{:CHPh}$, there was obtained with moderately concd. H_2SO_4 1-phenyl-tetralin-2-carboxylic acid (**XX**), stable towards KMnO_4 ; Ac_2O likewise did not split off H_2O but gave the oily acetates of the alc. acids. On cleavage of the ring with AcOH- or $\text{HCO}_2\text{H} \cdot \text{H}_2\text{SO}_4$, those acids having the Ph and CO_2H groups in the *trans*-position (**IIa**, **IIb** and **IIIa**) give the same **XI**, while **Ia**, with the Ph and CO_2H groups in the *cis*-position, gives chiefly **XII**. Assuming that the AcOH or HCO_2H adds at C atoms 2 and 3, **Ia** would give **XXI**, while **IIa**, **IIb** and **IIIa** would give the stereoisomeric **XXII**, irrespective of whether H_2O is split off before or after the addn. of the acid, thus seeming to confirm the assumption that after the shortening of the 4-membered ring in the truxillic and truxinic acids to the 3-membered ring in the I-IV the CO_2H and Ph groups remain on the same side of the ring. The I-IV were prepd. as already de-

scribed, partly by the degradation of γ -truxillic acid, partly by that of the ϵ -acid, which gives chiefly IIb. The NH_4 salt of the latter acid, heated 2.5–3 hrs. at $215\text{--}20^\circ$, gives 25% of the diamide (insol. in Na_2CO_3), 30% unchanged acid and 40% of the amidic acid. The diamide on half-sapon. with boiling alc. KOH yields a similar acid mixt. which is subjected, without sepn., to degradation with NaOCl ; the resulting 2,4'-diphenyl-3 ϵ -aminocyclobutane-1 ϵ -carboxylic acid, shaken with NOBr in cold Et_2O until dissolved, freed from excess of Br with dil. NaHSO_3 , shaken with Na_2CO_3 , dried and concd. yields in a few hrs. the almost pure lactone of IIb. XIII, m. $112\text{--}3^\circ$; Me ester, m. $62\text{--}2.5^\circ$. Acetate of XIII, oil; Me ester, m. $50\text{--}1^\circ$. XIV, m. $93\text{--}4.5^\circ$; Me ester, m. $64\text{--}4.5^\circ$. Acetate of XIV; Me ester, m. $69\text{--}70^\circ$. 1,4-Diphenyl-1-butanol, from $\text{PhCH}_2\text{CH}_2\text{CH}_2\text{MgBr}$ and BzH , b. $180\text{--}3^\circ$, m. $45\text{--}6^\circ$. XVI, m. $56\text{--}7^\circ$; oxime, m. $101\text{--}2^\circ$; semicarbazone, m. $126.5\text{--}7.5^\circ$. XVII, m. $131.5\text{--}2.5^\circ$, gives an intense blue color with alc. FeCl_3 . XX, m. $150\text{--}1^\circ$. IX, m. $155\text{--}6^\circ$, decolorizes KMnO_4 instantly, Br only after a long time; Me ester, m. $98\text{--}9^\circ$. C. A. R

The question of liquid crystals in stereoisomeric cinnamic acids. R. SROERMER AND FR. WODARG. Univ. Rostock. Ber. 61B, 2323–30(1928).—It had been observed that $p\text{-MeOC}_6\text{H}_4\text{CH:CHCO}_2\text{H}$ (I) no longer shows the phenomenon of liquid crystals when rearranged into its *allo*-form while this property immediately reappears when the *allo*-acid is rearranged back into the stable I. This is in harmony with Vorländer's views that the cryst. liquid form is most favored by an elongated, linear structure (thus, in C_6H_5 derivs., by *p*-substituents because *o*- and *m*-substituents produce an angular structure), for an angular structure is peculiar to the *allo*-form of unsatd acids. It has now been found that, in full agreement with such a theory, in a series of *p*-alkoxycinnamic acids, the stable, linear forms show enantiotropic cryst. liquid phases which never appear with the angular labile forms. It was attempted to lengthen the alkyl chain in order to increase the range of existence of the cryst. liquid phase. Below are the m. and clarification ps., resp. of the various *p*-alkoxycinnamic acids: MeO (I) 170° , 185° ; EtO (II) 190° , 196° ; PrO (III) 166° , 182° ; BuO (IV) 154° , 185.5° . The cetyl compd., however, did not show the phenomenon; in this case the straight chain has evidently, because of its enormous length, become too mobile to exert the necessary influence or produced decompn. at the m. p. It is worthy of note that substitution of PhCH_2 for the alkyl chain prevents the appearance of liquid crystals; the PhCH_2O acid (V) does not show the phenomenon. As was to be expected, however, branching of the alkyl chain has the same effect; the iso-BuO acid (VI) likewise does not form liquid crystals. In agreement with known facts, the esters of these acids show no cryst. liquid phases and the same is true of the amides, anisidides and *p*-toluidides of the *trans*- and some of the *cis*-acids. On the other hand, enantiotropic cryst. liquid derivs. are at once obtained on esterifying these acids with *p*-anisoleazophenol (VII) in accordance with Vorländer, the region of existence of the cryst. liquid phase being greatly extended as compared with that of the free acids. Below are the 2 m. ps. of the VII esters of the different acids: I 162° , about 320° ; *allo*-I 157° , about 301° ; II 178° , about 317° ; *allo*-II 172° , about 300° (decompn.); IV 177° , about 321° ; *allo*-IV 138° , about 300° (decompn.). These esters were prepd. from the acid chlorides in the presence of $\text{C}_6\text{H}_5\text{N}$. Because of the small differences, in some cases, between the m. ps. of the *cis*- and *trans*-forms, it was established in every case that in the prepn. of the *allo*-chlorides no rearrangement had occurred by converting a part of the chloride into the *allo*-amide which is converted into the stable amide by traces of Br in sunlight or obtained from the latter by radiation with ultra-violet light. The alkoxy-cinnamic acids were prepd. from the corresponding $\text{ROC}_6\text{H}_4\text{CHO}$ by the Perkin method, which, however, did not give a pure product in the case of V and failed completely in that of the cetyl deriv. (VIII). V and VIII were obtained in satisfactory yield only from $p\text{-HOC}_6\text{H}_4\text{CH:CHCO}_2\text{Me}$ with the calcd. quantity of KOH and PhCH_2Br or cetyl iodide. The *allo*-forms were obtained in 30–3% yields by 70 hrs exposure of the aq. Na salts to a Heraeus quartz Hg lamp. The stereoisomers can be sepd. by fractional crystn. but this can be effected far better and almost quant. by first pptg. the stable acid with AcOH and then the labile acid with HCl. *p*-Anisidide of I, m. 184° ; *p*-toluidide, m. 161° . *p*-EtOC $_6\text{H}_4\text{CH:CHCHO}$, m. $255\text{--}6^\circ$; semicarbazone, m. 202° (decompn.). Me ester of II, m. $68\text{--}9^\circ$; Et ester, m. 36° ; amide, m. 195° ; *p*-aniside, m. 179° ; *p*-toluidide, m. 164° . *allo*-II, much more sol. than the *trans*-form, m. 86° (decompn.). Me ester of III, m. 65° ; Et ester, m. 37° ; amide, m. $188\text{--}9^\circ$; *p*-aniside, m. 161° ; *p*-toluidide, m. $166\text{--}7^\circ$. *allo*-III, m. $90\text{--}1^\circ$; amide, m. 115° . *p*-Butyloxybenzaldehyde, yellowish, b. 285° . Me ester of IV, m. 77° ; Et ester, m. 38° ; amide, m. 184° . *p*-anisidide, m. 148° ; *p*-toluidide, m. $146\text{--}7^\circ$. *allo*-IV, m. 74° ; amide, m.

110°; *p*-anisidide, m. 114°. *p*-Isobutylbenzaldehyde, heavy, yellow oil easily oxidizing in the air, b. 258° in CO₂. VI, m. 159°. *p*-Benzoyloxybenzaldehyde, m. 72°. V, m. 199°. *p*-Cetyloxybenzaldehyde, m. 19°; phenylhydrazone, m. 89°. VIII, m. 200–2° (decompn.). *p*-Anisoleazophenyl benzoate, liquid crystals, m. 161° and 173°.

C. A. R.

The so-called liquid distyrene. R. STOERMER AND H. KOOTZ. Univ. Rostock. *Ber.* 61B, 2330–6(1928).—In connection with the detn. of the structure of the alleged diphenylcyclobutane, which turned out to be $\text{PhCH}_2\text{CH}:\text{CHPh}$, the dibromide of the long known "liquid distyrene" (I) was prepd. from a sample of I which had been made in 1923 and from which, at the time, had been obtained on bromination, together with the known dibromide m. 102° (II), a small quantity of an isomer m. 129° (III). On repeating the bromination of this old sample of I, no solid product at all could be obtained and much HBr was evolved. Believing that III might be the dibromide of the isomeric 1,3-diphenyl-2-butene, $\text{PhCH}_2\text{CH}:\text{CMePh}$ (IV), S. and K. synthesized IV from $\text{PhCH}_2\text{CH}_2\text{COMe}$ and PhMgBr through the intermediate carbinol (IVa). IV decomps. into PhCH_2CHO and MeCOPh on ozonization and forms a nitroschloride but no cryst. dibromide, and much HBr is evolved when it is treated with Br. No detectable change in its properties was produced by exposure to a quartz Hg lamp. Ozonization of the old sample of I now gave the same decompn. products as IV, showing that in the course of yrs. the double bond in I had shifted from the 1,2- to 2,3-position. The I, when prepd., had not been purified, and it was suspected that the rearrangement might have been produced by traces of H₂SO₄ adhering to the I, and as a matter of fact it was found that if in its prepn. the $\text{PhCH}:\text{CHCO}_2\text{H}$ is boiled with moderately concd. H₂SO₄ not merely a few hrs. but 1.5 days the product now behaves just like the above old sample of I. The same change can be effected by exposing pure I with a little I in CS₂ to sunlight for 3 days. Before such illumination the I on ozonization gives only BzOH and PhCHMeCHO , thus confirming the structure $\text{PhCH}:\text{CHHMePh}$ assigned to I by Stobbe and Posnjak. On brominating larger quantities of this pure I there were obtained, together with large amounts of II, m. 102° (although not sharply), a little III and, on carefully working up the mother liquors, a 3rd dibromide (V), m. 79°. Since the dibromide of I contains 3 asym. C atoms it can theoretically exist in 4 dl forms, and although the existence of such a 4th isomer could not be proved with certainty, indications of its presence were obtained. The lack of sharpness in the m. p. of II and the fact that it does not depress the m. p. of III suggested that I might be a mixt. and in fact, on crystg. it from petroleum ether instead of alc., it was sepd. into III and a dibromide, m. 122° (VI); a mixt. of equal parts of III and VI crystd. from alc. gives a product m. around 102°. II must therefore be stricken from the literature as a homogeneous compd. That III, V and VI are all derived from the same hydrocarbon (I) is shown by the fact that on debromination with Zn they all yield an unsatd. const. boiling compd. giving BzH and PhCHMeCHO on ozonization, having the same *n* in all 3 cases and again yielding III, V and VI on bromination. The I regenerated from the bromides never evolves HBr on bromination, so the product used by earlier investigators undoubtedly was contaminated with varying quantities of IV. Pure I is also completely colorless and non-fluorescent. Pure I regenerated from the bromides shows *n* 1.590, the product prepd. directly by the Fitts-Erdmann method 1.583, IV 1.577, and the old sample of I mentioned above showed 1.577. The F-E product must therefore contain only about 47% I with 53% IV. A sample of the original Posnjak prepn. of I, brominated after distn. *in vacuo* (which left a considerable residue of polymers), yielded a product, m. around 102°, which was sepd. into III and VI; not enough material was available to det. whether V was also present. IVa, b₁₂ 180–90°, m. 47–8°. IV, b₁₂ 169–70°, d₄²⁰ 1.0149, rapidly decolorizes KMnO₄ and Br, nitroschloride, m. around 126° (decompn.). Pure I b₁₂ 175–6. III seps. in stout crystals the size of a pea, VI in needles 1 mm. thick and 4 mm long. Further fractionation of the mother liquors from V finally gave a product m. 55–65° and the lowest m. p. obtained with mixts. of II and V was 65° (60% V, 40% II), so the above low melting product may have contained a 4th dibromide.

Hetero-ring formations with thiocarbohydrazide. IV. Reactions of 1-phenylthiocarbohydrazide. PRAPHULLA KUMAR GUHA AND SATYENDRA KUMAR ROY-CHoudhury. Dacca Univ. *J. Indian Chem. Soc.* 5, 163–74(1928); cf. C. A. 23, 139.—The reactions of acid chlorides, anhydrides and mustard oils with 1-phenylthiocarbohydrazide

(I), are studied. I with HCO₂H under reflux gives $\text{PhNHNH}:\text{C}:\text{N}:\text{N}:\text{CH}_2\text{S}$, m. 220°. I with Ac₂O gives the *mono-Ac deriv.*, m. 172–3°. I with EtOCSK in EtOH at 100°

for 5 hrs. gives PhNHNHC:N.NH.CO.S , m. 127° , this latter compd. is converted to the *disulfide*, m. 237° , by heating with FeCl_3 . I with COCl_2 , AcCl or BzCl gives only

the HCl salt of I. With $o\text{-C}_6\text{H}_4(\text{COCl})_2$ I gives $\text{PhNHNHC:N.NH.CO.C}_6\text{H}_4.\text{CO.S}$, m. 206° . With $\text{CH}_2(\text{COCl})_2$, $\text{PhNHNHC:N.NH.CO.CH}_2.\text{CO.S}$, m. $201\text{--}2^\circ$, is

formed. With SOCl_2 , PhNHNHC:N.NH.SO.S , m. 220° . The BzH and the $p\text{-NO}_2\text{C}_6\text{H}_4\text{CHO}$ derivs. of I in C_6H_6 soln. with COCl_2 give the ring compd.

$\text{PhCH:NN:C.NH.NPh.CO.S}$, m. $204\text{--}5^\circ$, and the corresponding NO_2 deriv., m. 258° . I with PhNCO gives $\text{PhNHNHCSNHNHCONHPh}$ (II), recrystd. from MeOH , m. 209° ; with PhNCS I gives the *thio deriv.* (III), m. $173\text{--}4^\circ$. PhNMcNHCSNHNH_2 and $m\text{-MeC}_6\text{H}_4\text{NHNHCSNHNH}_2$ with PhNCS give compds. m. $219\text{--}20^\circ$ and 160° ,

resp. II with 20% KOH for 0.5 hr. gives the ring compd. $\text{PhNHNHC:N.NH.CO.NPh}$ crystd. from dil. alc., m. $244\text{--}245^\circ$. III with 20% KOH 0.5 hrs. gives an oil (PhNH_2) which could be removed by steam distn. leaving a solid which crystd. in white plates,

$\text{PhNHNHC:N.N:C(NHPh).S}$, m. 199° ; the mother liquor on acidification with HCl

sepd. white plates $\text{PhNHNHC:N.N:C(SH).S}$, m. $258\text{--}9^\circ$. This compd. with FeCl_3 gives the corresponding *disulfide*, m. 205° , while heating with Ac_2O gives the *tri-Ac deriv.*, m. $206\text{--}7^\circ$. III boiled for 1.5 hrs. with concd. HCl on hydrolysis gives

OC.NH.NH.CO.S , m. 222° . III with FeCl_3 for 0.5 hrs. gives $\text{PhN:NC:N.N:C(NHPh).S}$, m. $256\text{--}7^\circ$. PhNHN:C(SH)SMe (IV), with $(\text{NH}_2\text{CH}_2)_2$ at once gives

$\text{PhNHN:C.NH.CH}_2.\text{CH}_2.\text{S}$, m. 223° (from $\text{C}_6\text{H}_5\text{N}$). IV with $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$ at

$130\text{--}40^\circ$ for 4 hrs. gives $\text{NH.C}_6\text{H}_4.\text{NPh.N:C(SH)}$, m. 293° (from HOAc); *Ac deriv.*, m. $203\text{--}4^\circ$; *disulfide* by oxidation with FeCl_3 , m. above 300° . D. H. POWERS

Synthesis of cyclobutane acids. I. Norpinic acid. CARL A. KERR. Univ. of Michigan. *J. Am. Chem. Soc.* 51, 614-9(1929).—The condensation of substituted α,α' -dicyanoglutarimides with CH_2I_2 and hydrolysis of the resulting dicyclic compds is a satisfactory method for the formation of substituted cyclobutane acids. β,β -Dimethyl- α,α' -dicyanoglutarimide (20 g.) and 7.2 g. Na in 100 cc. MeOH , refluxed 1 hr and then treated with 44 g. CH_2I_2 with refluxing for 1.5 hrs., give 12 g. *dicyanonorpinimide* (I), m. $305\text{--}6^\circ$ (decompn.) (*Ag salt*). H_2SO_4 gives glutaric acid. Heating 10 g I and 180 cc. 2.15% NaOH gives 5 g. *sym-dicarbamylnorpinic acid* (II), m. 190° (decompn.) and 4 g. *sym-dicyanonorpinic acid* (III), m. $225\text{--}6^\circ$ (decompn.), whose *di-Me ester*, m. $139\text{--}40^\circ$. Evapn. of an aq. soln. of II gives the NH_4 salt of 1-carbamyl-2,2-dimethylcyclobutane-1,3,3-tricarboxylic acid (?); the free acid m. 236° . Refluxing 3.7 g. II with 50 cc. 10% NaOH for 9 hrs. and acidifying gives 2,2-dimethylcyclobutane-1,1,3,3-tetracarboxylic acid (IV), m. 200° (*Ag salt*; *tetra-Me ester*, b_{25} 100°). Heating III with 20% NaOH also gives IV. Heating IV at $200\text{--}5^\circ$ for 0.5 hr. gives *trans-norpinic acid*, m. 146° . C. J. WEST

Alkylation of hydroxymethylenecyclohexanone. HEMENDRA KUMAR SEN AND KANAILAL MONDAL. *J. Indian Chem. Soc.* 5, 609-30(1928).—Contrary to expectation, the reaction between the Na salt of hydroxymethylenecyclohexanone (I) and alkyl iodides (II) gave products which on hydrolysis gave *o*-alkyl-substituted ketones. The first product formed from the Na salt of I and II is a substituted keto-aldehyde as shown by its reduction of $\text{NH}_3\text{-AgNO}_3$ and Cu salt solns. This behavior of I is very different from usual and can be explained best by assuming an aldehydic structure of the Na compd. of I and a direct substitution of the Na by alkyl. To substantiate this view S. and M. show (by Meyer's method) that the hydroxymethylene compds. (III) exist in keto and enol forms. The keto-enol equil. is shifted by different solvents as would be expected, showing therefore the existence of the aldehydic Na compd. AcCl and BzCl react with the Na salts of III, in the usual way, by substitution in the enolic Na . This is in accordance with Lapworth's view. Alk. hydrolysis of the *C*-alkyl ethers of III gives alkylated ketones. This reaction was found to be general with cyclohexanone and substituted cyclohexanones when one *o*-position is free to yield III. The Na salt of I, prepd. by heating I in dry benzene with Na on a water

bath 18 hrs., is heated with MeI 12 hrs. at 100°. The mixt. is cooled, filtered and distd., giving a liquid (IV), b_m 180–50°. Distn. of IV with dil. NaOH gives *o*-methylcyclohexanone. Similar results were obtained by refluxing I in alc. with NaOEt and MeI, or by heating this mixt. in a water bath under pressure. Other alkyl derivs. of I prepd. in similar ways were *o*-Et, 2,5- and 2,6-Me₂, 2,4-Me₂ (impure), 2-methyl-6-benzyl-, 2,3,4-Me₃, and menthone. AcCl and the Na salt of I give an acetate of the enol form; semicarbazone, m. 182–4°. BzCl and hydroxymethylene-*o*-methylcyclohexanone give an unstable benzoate, m. 85°; semicarbazone, m. 175°. Corresponding benzoate of *p*-deriv., m. 95°; semicarbazone, m. 183–4°. The actions of MeI and EtI on hydroxymethyleneacetophenone were studied, but small yields of indefinite products were obtained.

FREDERICK C. HAHN

Action of hypochlorous acid on benzene hydrocarbons. F. W. KLINGSTEDT, G. WIRSE AND G. RUDBÄCK. *Acta acad. Abensis math. phys.* 4, No. 2, 1–36 (1927).—HClO yields with C₆H₆ α - and β -benzene hexachloride, PhCl, and a compd., C₆H₅OC₂Cl₃; with C₁₀H₈ naphthalene dichloride and tetrachloride, 1-C₁₀H₇Cl, and 1,4-C₁₀H₆Cl₂; with toluene, *m*- and *p*-xylene, and *p*-isopropyltoluene only monosubstitution products were obtained. With dil. acid substitution is the chief reaction, and with more concd. acid, addn.; also only substitution derivs. are obtained in the dark. Modifications in the course of the reaction are observed when the acid reacts in presence of Hg oxide or oxychloride (cf. Carius and Neuhoft, *Ann.* 136, 323, 342 (1865)). B. C. A.

Catalytic activity of aluminum chloride. GREGG DOUGHERTY. Princeton Univ. *J. Am. Chem. Soc.* 51, 576–80 (1929).—A mechanism for the Friedel-Crafts reaction is suggested. The hypothesis predicts that metathetical reactions will occur between certain types of aliphatic halogen compds. in the presence of AlCl₃. Exptl. evidence is given that such reactions do occur. Thus, CHCl₃ and EtBr with AlCl₃ at room temp. give EtCl and about 35% of CHCl₂Br, while C₂H₅Cl₂ and C₂H₅Br₂, after 35 hrs. at 25°, give C₂H₅ClBr; the latter reaction is reversible. C. J. WEST

Nitration of substituted anilines. E. RAYMOND RIEGEL, HOWARD W. POST AND F. FRANK REID. Univ. of Buffalo and Johns Hopkins Univ. *J. Am. Chem. Soc.* 51, 505–8 (1929).—Nitrated with mixed acids under similar conditions, the following % of original NH₂ remained after the nitration: *p*-H₂NC₆H₄OH, 72.6; 2,3-HO(H₂N)-CH₂CO₂H, 42.5; 3,4-H₂N(HO)C₆H₃SO₃H, 40.0; *p*-H₂NC₆H₄SO₃H, 34.0; *m*-H₂NC₆H₄HSO₃H, 26.7; 3,4-HO(NH₂)C₆H₃SO₃H, 4.8; *o*-H₂NC₆H₄OH, 3.4; H₂N(HO)C₆H₃CO₂H, 2.1; H₂N(HO)C₆H₃Me, 2.4; H₂N(O₂N)C₆H₃OH, *o*-H₂NC₆H₄CO₂H, 4.6; HO(SO₃H)C₆H₃NH₂, *m*-H₂NC₆H₄OH, 0; 2,4-HO(SO₃H)C₆H₃NH₂, 49. The influence of the groups depends on their position: 2 electronegative groups *p* to each other seem to make the resultant mol. more resistant to oxidation. C. J. WEST

Monoarylguanidines. I. α -Phenylguanidine. G. B. L. SMITH. Polytechnic Inst., Brooklyn. *J. Am. Chem. Soc.* 51, 476–9 (1929).—[MeSC(:NH)NH₂]₂.H₂SO₄, 555 g. and 740 cc. PhNH₂, heated until the evolution of MeSH ceases, give a product contg. about 30% PhNH₂ (as sulfate); the (PhNH₂C(:NH)NH₂)₂.H₂SO₄ cannot be purified by crvstn. from H₂O, but purification may be accomplished by converting the sulfate into the carbonate, which is only slightly sol. in cold H₂O; the HCl and H₂SO₄ salts are described and crystallographic data are given for the free base, H₂SO₄, HCl, HNO₃ salts, picrate and chloroplatinate. C. J. WEST

Identification of the reduction products of azo dyes. III. Classification and identification of compounds belonging to group B. SHIGEZO UENO. *Bull. Inst. Phys. Chem. Research Tokyo* 7, 398–438; *Abstracts* 1, 37–40 (1928); cf. C. A. 22, 3390. The reduction products of azo dyes, the NH₂OH soln. of which manifests in a short time a certain coloration on a filter paper through oxidation by air (compds. of group B) are classified: Class IXa: By addn. of FeCl₃ soln. to a dil. soln. of the HCl salt of any compd. of this class, or on adding NaNO₂ soln. to the ice cold dil. soln. acidified with HCl, a fugitive green color is obtained: *p*-C₆H₄(NH₂)₂, *p*-tolylenediamine, 2-methoxy-, 2,5-dimethyl-, 2-methyl-5-methoxy-, and 2-chloro-1,4-diaminobenzenes, 1,4-C₁₀H₆(NH₂)₂, 2,1,4-C₁₀H₃(OEt)(NH₂)₂, 4,1-C₁₀H₄(NH₂)Et, 4-amino- α -naphthylglycine. Class IXb: A dil. soln. of the HCl salt of any compd. of this class does not give a green color with FeCl₃ or HNO₃. On boiling the dil. soln. with FeCl₃, a quinone smell is perceived. It gives the indamine reaction and the methylene blue reaction. *p*-H₂NC₆H₄NMe₂, *p*-H₂NC₆H₄NHEt. Class X: A suspension in H₂O or a very dil. soln. assumes a green color on adding FeCl₃; the color is not changed by boiling, or HCl addn. Most of the compds. belonging to this class are difficultly sol. in H₂O. 1,2-diaminonaphthalenesulfonic acids (SO₃H = 4, 5, 6 or 7), 1-amino-2-ethylaminonaphthalene-7-sulfonic acid, 1,2-diaminonaphthalene-3,6-disulfonic acid. Class XI: The free acids are difficultly sol. in H₂O. A suspension in water or an aq. soln.

assumes a fugitive or otherwise not easily changeable green color. It gives the indamine reaction. The filter paper moistened with the soln. containing CaCO_3 gives a very feeble coloration by air oxidation, or not at all; on spotting it with FeCl_3 , a fugitive green coloration is obtained: 1,4-diaminobenzene-2-sulfonic acid, 1,4-diaminonaphthalenesulfonic acids ($\text{SO}_3\text{H} = 2$ or 6). Class XII: On adding FeCl_3 soln., a suspension in H_2O assumes a little dark red color which becomes very faint or disappears upon boiling. Aniline or *p*-toluidine is obtained as a decompn. product by boiling with HCl : 4-amino-1-phenylaminonaphthalene-8-sulfonic acid, 4-amino-1-*p*-tolylaminonaphthalene-8-sulfonic acid. Class XIII: A dil. soln. or suspension in H_2O assumes a yellow to brown color with FeCl_3 . The soln. contg. CaCO_3 or the NH_4OH soln. assumes a green color on filter paper by air oxidation. If this green color is further changed to another color, it can be restored by exposure to NH_3 vapors for a short time: 2-amino-1-naphtholsulfonic acids ($\text{SO}_3\text{H} = 3, 4, \text{ or } 5$), 2-amino-1-naphtholdisulfonic acids ($\text{SO}_3\text{H}:\text{SO}_3\text{H} = 3:6, 4:7 \text{ or } 4:8$), 6-amino-2-acetamido-5-naphthol-7-sulfonic acid, 7-amino-2-acetamido-8-naphthol-6-sulfonic acid, 6-amino-2-benzoylamino-5-naphthol-7-sulfonic acid. Class XIV: A suspension in water or a dil. soln. assumes a yellow to pale brown color with FeCl_3 . The filter paper moistened with the soln. contg. CaCO_3 is not colored green by air oxidation. This is also the case even by exposing to NH_3 vapors. The filter paper moistened with the NH_4OH soln. assumes a yellow to brown color by air oxidation: 1-amino-2-naphthol, 1-amino-2-naphthol-3-carboxylic acid, 1-amino-2-naphtholsulfonic acids ($\text{SO}_3\text{H} = 4, 6, 7, \text{ or } 8$), 2-amino-1-naphthol-3,8-disulfonic acid, 1-amino-2-naphtholdisulfonic acids ($\text{SO}_3\text{H}:\text{SO}_3\text{H} = 3:6, 3:7 \text{ or } 6:8$). Class XV: On adding FeCl_3 , an aq. soln. assumes a pale yellow-brown color which turns green immediately. The aq. soln. acidified with HCl turns orange-yellow on adding NaNO_2 soln. The filter paper moistened with the NH_4OH soln. becomes yellow to brownish yellow by air oxidation: 2-amino-1-naphthol- and 1-amino-2-naphthol-3,6,8-trisulfonic acid. Class XVI: When a suspension in water or a dilute soln. is mixed with NaNO_2 soln., in presence of ice, and made alk. with a cold soln. of Na_2CO_3 after a short time it assumes a clear red, bluish red, blue or green color which returns to the original one (orange to brown) on acidulation: 2-amino-1,5-dihydroxynaphthalene, 1-amino-2,7-dihydroxynaphthalene, 2-amino-1,7-dihydroxynaphthalene-4-sulfonic acid, 2-amino-1,8-dihydroxynaphthalene-3,6-disulfonic acid, 2-amino-1,7-dihydroxy-6-carboxynaphthalene-3-sulfonic acid, 1,2-diamino-5-naphthol-7-sulfonic acid, 1,2-diamino-8-naphthol-6-sulfonic acid.

ALBERT L. HENNE

2,3-, 2,5-, 2,6-, and 3,5-Dibromophenylhydrazines, *p*-bromophenylmethylhydrazine and their derivatives with aldehydes and ketones. E. VOTOČEK AND R. LUKES. *Chem. Listy* 22, 217-25 (1928).—The following 2,5-dibromophenylhydrazones were prepd.: acetone, m. 73° ; benzaldehyde, m. 79° ; furfuraldehyde, m. 104° ; arabinose, m. $170-5^\circ$; rhamnose, m. 184° ; galactose, m. 207° ; and the corresponding glucosazone, m. $228-9^\circ$. The following 3,5-dibromophenylhydrazones were prepd.: acetone, m. $85-6^\circ$; benzaldehyde, m. $106-7^\circ$; furfuraldehyde, m. 116° ; and dextrose, m. 172° . 2,3-Dibromophenylhydrazine, m. 112° (benzylidene deriv., m. 106°), and 2,6-dibromophenylhydrazine, m. 110° (benzylidene deriv., m. $51-2^\circ$; furfurylidene deriv., m. 62°), were prepd. as *p*-Bromophenylmethylhydrazine, m. 33° , was prepd. by bromination of PhNMeNH_2 , and also, in order to establish the position of the Br atom, from *p*- $\text{BrC}_6\text{H}_4\text{NH}_2$, by way of *p*-bromophenylmethylnitrosoamine, m. 74° ; the corresponding hydrazone of benzaldehyde, m. $106-7^\circ$, and the osazone of levulose, m. 153° , were prepd. The above bromohydrazones are in no way better for the identification of sugars than those commonly used.

B. C. A.

Derivatives of mono- and diaminohydroxyphenylarsonic acids. BARRETT C. FISHER AND GEORGE W. RAIZISS. Dermatological Research Labs, Philadelphia, Pa. *J. Am. Chem. Soc.* 51, 527-32 (1929).—The *Li* salt, crystg. with $2\text{H}_2\text{O}$, the *Ca* salt, crystg. with $2\text{H}_2\text{O}$, the *Ba* and *Sr* salts of 3-acetyl-amino-4-hydroxyphenylarsonic acid are described. 3-Nitro-4-hydroxyphenylarsonic acid (263 g.), 160 g. Br and 20 g. Fe in MeOH give 154 g. of the 5-Br deriv., yellow, begins to decomp. 280° ; the corresponding 3- NH_2 acid (I) also gives a 5-Br deriv. (II), whose *Ac* deriv. darkens at $267-70^\circ$ but is unmelted at 300° . 3,5-Diamino-4-hydroxyphenylarsonic acid yields the following acyl derivs.: *formyl*, begins to decomp. at 200° ; *Ac* (III), darkens at $235-40^\circ$; *propionyl*, m. $197-8^\circ$; *butyryl*, m. 177° ; *chloroacetyl*, m. $210-1^\circ$ (decompn.). II is neither more trypanocidal or spirocheticidal than I or its *N*-Ac deriv. The least toxic of all the compds. discussed above is III; when injected intravenously into white rats its max. tolerated dose is 4.6 times greater than that of the *Ac* deriv. of I.

C. J. WEST

Mercuration of resorcinol and some alkylresorcinols. REUBEN B. SANDIN. Univ.

of Alberta. *J. Am. Chem. Soc.* **51**, 479–83 (1929).—1,3,4-(HO)₂C₆H₃Et (1.4 g.) and 6.37 g. Hg(OAc)₂ in EtOH-AcOH give 97% of *anhydromercuriaceloxymercuriethylresorcinol* (I), yellow, darkens on exposure to light and when heated at 180° but does not m. 300°. Aq. HCl converts I into the *dichlorodimercuri deriv.*, decomps. 207–9° (cor.); from EtOH this also tends to sep. as a yellow *anhydromercuri deriv.* CO₂ bubbled through I in NaOH gives an *anhydromercurihydroxymercuri deriv.*, dark brown solid. One mol. Hg(OAc)₂ and 2 mols. (HO)₂C₆H₃Et, in AcOH, upon pouring into H₂O, give the *6-aceloxymercuri deriv.*, m. 163–4° (cor.), or, if poured into salt soln., the *chloromercuri deriv.*, m. 145–6° (cor.). These have not been sepd. into isomeric forms. Similarly were prepd. *anhydromercuriaceloxymercurihexylresorcinol*, bright yellow, darkens 200°, does not m. 300°, in quant. yields; the *dichloromercuri deriv.*, yellow, m. 137–8° (cor.); and the *celoxymercuri deriv.*, m. 177–8° (cor.). *m*-C₆H₄(OH)₂ (1.1 g.) and 9.56 g. Hg(OAc)₂ in EtOH-AcOH give quant. a *trimercurated deriv.*, yellow, darkens 210°, does not m. 300°. C. J. WEST

Replacement of carboxyl by mercury in certain 3-substituted phthalic acids. Preliminary paper. FRANK C. WHITMORE AND PAUL J. CULHANE. Northwestern Univ. *J. Am. Chem. Soc.* **51**, 602–5 (1929).—Heating 211 g. 3,1,2-O₂NC₆H₃(CO₂H)₂ in 800 cc. H₂O and 80 g. NaOH with 350 g. Hg(OAc)₂ in 700 cc. H₂O and 50 cc. AcOH for 70 hrs. at 170° (complete evolution of CO₂ and complete soly. in NaOH) gives 90% of *anhydro-2-hydroxymercuri-3-nitrobenzoic acid*; this can be refluxed with fuming HNO₃ without breaking the C-Hg linkage but a short heating with concd. HCl removes the Hg completely from the org. mol.; the Hg compd. reacts with Br and I to give good yields of the otherwise difficultly obtainable 2-bromo- and 2-iodo-3-nitrobenzoic acid 3-Br- and 3-IC₆H₃(CO₂H)₂ behave similarly. The mercuriation reaction consists in the replacement of the 2-CO₂H group by Hg. C. J. WEST

Orientation in the benzene ring. The bromination of 2-aminoresorcinol dimethyl ether. ARTHUR A. LEVINE AND HOOPER LINFORD. State Coll. of Washington. *J. Am. Chem. Soc.* **51**, 524–7 (1929).—Bromination of 1,3,2-(MeO)₂C₆H₃NHAc with 2 equivs. of Br gives a *mono-Br product*, m. 161–2° (I) and a *di-Br deriv.*, m. 212–3° (II). 4 equivs. of Br at room temp. give II, while on the H₂O bath there results an isomeric *di-Br deriv.*, m. 187–8° (III). Bromination of 1,3,2-(MeO)₂C₆H₃NH₂ gives I, while if an excess of Br is used at 100°, III results. I is the *4-Br deriv.*, and on hydrolysis yields *4-bromo-2-aminoresorcinol di-Me ether*, m. 67–8°, also obtained by reduction of the corresponding 2-NO₂ deriv. C. J. WEST

Oxidation of tribromoresorcinol. TENNEY L. DAVIS AND JULIAN W. HILL. Mass. Inst. Tech. *J. Am. Chem. Soc.* **51**, 493–501 (1929).—Oxidation of tribromoresorcinol (I) in C₆H₆ with aq. CrO₃ gives a mixt. of tribromoresoquinone (II), *rhodo-(bromo)-resoquinone* (III) and *tetrabromoresoquinone* (IV), sepd. by crystn. from dry C₆H₆ and mech. sepn. of the crystals. III, the main product of the reaction, crystallizes with C₆H₆, Et₂O, CS₂, CCl₄ and CHBr₃; it m. about 220° (decompn.); free from solvent, it forms a red powder, giving a dark green or black soln. in dil. NaOH and a deep red color in concd. H₂SO₄; it oxidizes the usual ketone reagents with evolution of N. Reduction gives 3,5,3',5'-*tetrabromo-2,4,2',4'-tetrahydroxydiphenyl* (V), m. 277–8°; *tetra-Ac deriv.*, m. 194–5°. II is similarly reduced to the same compd. The action of Br in 50% AcOH gives II, showing that III is intermediate between II and V. The action of heat on III (1 day at 95° and 2 days at 120°) gives a *compd.* C₁₂H₂O₂Br₆, m. 228–9°, which has only 0.5 the oxidizing power of III; it is either isomeric or polymeric with III. IV, m. 227–8° (decompn.); in boiling AcOH it gives II; reduction gives V. II or III is converted into IV with pure Br. The action of CrO₃ on I appears to be first the oxidation of 1 HO group and the removal of 1 Br atom from the nucleus. The resulting intermediate substance apparently doubles up to form the at present unknown dibromoresoquinone; the products which have been isolated are brominated derivs. of this substance. C. J. WEST

Orcein-like dyes. II. F. HENRICH AND W. HEROLD. Univ. Erlangen. *Ber.* **61B**, 2343–9 (1928), cf. C. A. **22**, 2375.—Henrich had obtained by oxidation of amino-orcinol (I) in faintly alk. soln. orcein- and litmus-like dyes of the indophenol group and has since been attempting to build these substances up from the simplest units. The first thing that suggested itself was the synthesis of the hydroxytoluquinone monoinine (II) derived from I. By the Willstätter method of oxidation (carefully dried Ag₂O) H. and Müller readily obtained O:C₆H₄Me:NH (III) from 3,4-Me(H₂N)C₆H₃OH (IV); to their report it may be added that when the Et₂O soln. of the III, after filtration from the Ag₂O, is concd. and cooled, the III seps. in yellow crystals which, after recrystn. from Et₂O, m. 59° and are stable for a long time, especially in the dark. With the isomeric *o*-amino-*m*-cresol, in which the OH is in the *o*-position to the NH₂ group, the

results were not so simple. I, which has OH groups in both the *o*- and *p*-positions to the NH₂ group, forms no quinone imine when shaken or heated in abs. Et₂O or C₆H₆ with pure Ag₂O and anhyd. Na₂SO₄; the Ag₂O seems to be partly reduced and indications were obtained that it contains solid reaction products but these neither have indophenol-like properties nor give blue colors with alk. phenol solns. 3,4,5-Me(H₂N)(MeO)C₆H₂OH (V) (prepd. by reduction of the NO₂ compd.), begins to darken 170°, decomps. above 190°, in which the HO group in I in the *o*-position to the NH₂ group is methylated, gives with Ag₂O and Na₂SO₄ in Et₂O 3-methyl-5-methoxyquinone 4-imine (VI), yellow, m. 111°, unchanged by a few hrs. exposure to direct sunlight, stable for weeks in a desiccator, produces violent sneezing in powder form, sol. in most org. solvents in the cold with yellow color, decolorized by Zn dust in AcOH, regenerates V with SnCl₂ and HCl, slowly dissolves in H₂O at room temp. with light yellow color and neutral reaction to litmus; on heating, the aq. soln. becomes brown-red and on boiling it evolves NH₃ and deposits a brown substance which does not m. 280° and is sol. in acids but not in alkalis. When the aq. soln. is exposed, in a porcelain dish half covered with black paper, to direct sunlight, the illuminated portion soon darkens while the other part remains yellow; an unilluminated aq. suspension allowed to dry leaves a pale yellow residue, m. 130°. NaOH slowly dissolves VI with red-yellow color and dark flocks sep. from the soln. Finely powd. VI added to dil. HCl, HNO₃ or H₂SO₄ at once gives a difficultly sol. salt more intensely yellow than the VI itself, and an intensely yellow picrate is obtained with picric acid in Et₂O. Dry HCl in Et₂O gives a deep yellow HCl salt which, when filtered, rapidly becomes lighter in color and finally gray-white; when spread on clay and dried *in vacuo* over lime and H₂SO₄ it becomes almost white. When solid VI is added to PhOH in alkali or a faintly alk. soln. of PhOH is layered with VI in Et₂O there gradually develops a blue color changing to red on acidification; resorcinol at once gives a blue, orcinol an intense red and cresorcinol a violet color; orcinol slowly gives the color even in the absence of alkali. With SO₂ the Et₂O soln. of VI gradually becomes colorless and deposits a gray ppt. which after a time becomes dark and flocculent and, when filtered, forms a brown-red, somewhat tarry mass sol. with blue color in acids and AcOH, and also in alc. The H₂O soln. of VI is not completely decolorized by SO₂; after a time there sep. colorless crystals which contain N, are difficultly sol. in H₂O and are attacked by concd. H₂SO₄ only on heating. The 3,2,5-isomer of V, in which the *o*-HO group to the NH₂ residue is free, gives with Ag₂O 3-methyl-5-methoxyquinone 2-monoimine (VII), orange yellow, m. 61°, becomes dark with acids (including AcOH), gives an almost black ppt. with picric acid in Et₂O, slowly dissolves in NaOH with orange color and deposits a red substance, gradually dissolves in H₂O with yellow color but soon deposits the red substance, m. 253°, formerly obtained (*Ber.* 30, 1107(1897)) by treatment of the reduction product of a nitrosoorcinol mono-Me ether in faintly alk. soln. with air. In an oxidation of free I in boiling abs. alc. with dry air, recently described, were obtained orcein-like dyes, the difficultly sol. part of which gave on analysis values indicating a trimol. formula. To preclude the possibility that this might have been contaminated with NH₃, set free at the beginning of the reaction, the dye was repeatedly extd. with dil. HCl and carefully washed with H₂O, when it again gave on analysis values agreeing with those calcd. for the trimol. formula. When extd. several days and nights in a Soxhlet with alc., most of it dissolved but the residue still had the same compn. The dye now contained only 0.2% ash and when decompd. with SnCl₂ and HCl no longer gave I.HCl. The alc.-sol. portion, however, extd. 2 days with Et₂O, rubbed 3 times with dil. HNO₃ and washed with H₂O to ensure removal of any I possibly still remaining gave considerable I.HCl with SnCl₂-HCl (1.4 g. from 8 g. dye). C. A. R.

Reactions relating to carbohydrates and polysaccharides. XXI. Comparison of tendencies of saturated and unsaturated aldehydes towards cyclic acetal formation. HAROLD HIBBERT, EDWARD O. HOUGHTON AND K. AUSTIN TAYLOR. McGill Univ. *J. Am. Chem. Soc.* 51, 611-4(1929); cf. *C. A.* 23, 818.—A comparison is made of the tendency of satd. and unsatd. aldehydes to form cyclic acetals. The aldehydes were condensed with (CH₂OH)₂, dil. H₂SO₄ or H₃PO₄ being used as catalyst. The unsatd. aldehydes, PhCH:CHCHO, MeCH:CHCHO and EtCH:CMCHO, show practically no tendency towards cyclic acetal formation under the exptl. conditions used. *β*-Phenyl-*α,β*-dichloropropylideneethylene glycol, b₁₂ 104-6° (37% yield); *α*-monochlorocinnamylidene deriv., m. 69-70° (22% yield); dichlorobutylidene deriv., b₁₂₋₁₃ 100-5° (50.3% yield); *α*-monochlorocrotylidene deriv., b₁₂ 76-80° (22% yield). The greater tendency of the unsatd. aldehydes contg. Cl attached to the *α*-C atom to form cyclic acetals is probably due to the activating influence exerted by the negative Cl atom on the CO group. XXII. The isomeric cinnamylidene glycerols. H. HIBBERT AND MYRON

S. WHELEN. *Ibid* 620-5.— PhCH:CHCHO and $\text{C}_3\text{H}_7(\text{OH})_3$, heated with a small quantity of 40% H_2SO_4 under reduced pressure, readily condense to give a mixt. of 1,1'-cinnamylideneglycerol, m. 121° (β -Me ether, m. $79-80^\circ$) and the 1,2-deriv., which could not be purified but whose constitution was established by the prepn. of the α -Me ether, b_p $164-8^\circ$, n_D^{20} 1.5455 and hydrolysis to the glycerol α -Me ether. When compared with the methyldene and benzylidene derivs., the cinnamylidene derivs. exhibit a very much more pronounced tendency towards hydrolysis. C. J. WEST

Catechin problem. FREDERICK A. MASON. *J. Soc. Chem. Ind.* 47, 269-76T. (1928).—A review of the work of Freudenberg on the structure of gambier catechin.

H. B. MERRILL

Tautomerism of phloracetophenone and related compounds. ADOLF SONN AND KURT WINZER. *Univ. Königsberg i. Pr. Ber.* 61B, 2303-6(1928).—Under certain conditions 1 of the 3HO groups in phloracetophenone (I) behaves differently from the other 2 (with CH_3N_2 also, only 2 of the HO groups react smoothly; see preceding abstr.) and I was accordingly assigned the structure II (C. A. 20, 375). I and a no. of its derivs. in MeOH and CHCl_3 have now been titrated by the Meyer Br method. I and its mono-Me ethers in 15 sec. take up approx. the 2 equivs. Br calcd. for formula II. Phloroglucinol (III) and resorcinol (IV) in MeOH take up about 2.5 equivs. Br in 15 sec. and while III does not take up more on longer action (2 and 10 min.), IV absorbs 2.9 and 3 mols. Br in 45 sec. and 2 min., resp. Dimethyldihydroresorcinol (V) in MeOH takes up about 0.5 equiv. in 15 sec. and no more in even 2 hrs.; in CHCl_3 exactly 1 equiv. is used up. In CHCl_3 the di-Me ether of I in 15 sec. uses up 1.8 equivs. Br, diacetotriketohexamethylene 1.0, triacetotriketohexamethylene 0.15, tri-Me ether of III 1.8. It may be concluded with certainty that I and III, like V, contain in soln. ketonic groups as shown in the formulas II and V. *Et 4-hydroxy-2,6-diethoxybenzoate*, from 4,2,6-MeO₂CO(HO)₂C₆H₂CO₂H and MeCHN₂ in Et₂O, followed by sapon. of the MeO₂CO group with *N* aq. alc. NaOH at room temp., m. $180-1^\circ$. *4-Methoxy-2,6-diethoxybenzoic acid*, from 4,2,6-MeO(HO)₂C₆H₂CO₂Me with MeCHN₂, the crude product bmt. washed with dil. alkali and sapond. with cold coned. H_2SO_4 , m. 166° (effervescence) (Me ester, m. 95°); the alk. washings of the crude product give on acidification *Me6(2)-hydroxy-4-methoxy-2(6)-ethoxybenzoate*, m. $97-8^\circ$, gives a violet color with FeCl_3 in alc.

C. A. R.

Phloracetophenone monomethyl ethers and the supposed hydroxypeonol. ADOLF SONN. *Univ. Königsberg i. Pr. Ber.* 61B, 2300 2(1928); cf. C. A. 20, 375.—The structure 4,2,6- and 2,4,6-Me(HO)₂C₆H₂COMe assigned to the phloracetophenone Me ether: m. $136-7^\circ$ (I) and $205-7^\circ$ (II), resp., have been confirmed. Both I and II give with CH_3N_2 the long known 2,4,6-HO(MeO)₂C₆H₂COMe (III) which with EtI and alkali yields 2,4,6-EtO(MeO)₂C₆H₂COMe (IV), also obtained from I by successive treatment with MeCHN₂ and alk. MeI, while II under these conditions gives the isomeric 4,2-EtO(MeO)₂C₆H₂COMe (V). Neither I nor II is appreciably volatile with steam and the much lower melting (80°) "hydroxypeonol" obtained by steam distn. of an alc. soln. of *Xanthorrhoea* resins (Finlayson, C. A. 21, 798) cannot have been a phloracetophenone mono-Me ether; its m. p. and properties indicate rather that it is the di-Me ether (III), described in the literature as m. 80° to $85-8^\circ$, as being volatile with steam and as having already been found in nature. *Phloracetophenone 2(6)-Et 4(2)-di-Me ether* (IV), m. $69-70^\circ$. *2(6)-Et 4-Me ether*, from I and MeCHN₂, m. $133-4^\circ$. *2(6)-Me 4-Et ether*, from II and MeCHN₂, m. $56-7^\circ$. *4-Et 2,6-di-Me ether* (V), m. $81-2^\circ$, depresses the m. p. of IV. C. A. R.

The so-called nitro humic acids. W. FUCHS. *Brennstoff-Chem.* 9, 178-82(1928); cf. C. A. 22, 583.—Humic acid was prepd. from Kassel brown coal by treatment in the cold for several days with 5% HCl and extn. of the bitumens with EtOH: C₆H₆ (1:1) soln. The humic acid was then nitrated with 5 *N* HNO₃ and the product (as well as its methyl derivs.) was found practically completely sol. in (CH₃)₂CO. Mol. wts. found in acetone soln. for the nitro compd. were 1240 to 1290; for the methyl deriv. 250 to 400. The N introduced by treatment with 5 *N* HNO₃ was not present as NO₂ as it could not be detd. as such and could not be reduced to NH₃. Chem. behavior indicated presence of N as :NOH. The first stage of reaction with HNO₃ probably is oxidation forming the group CO-CH₃ and HNO₂ from which the oxime is formed. When urea (sufficient to take up HNO₂ formed) was added no N entered the humic acid. J. D. DAVIS

Pyrohymatomelanic acid, a new compound isolated from Merck's humic acid. D. J. W. KREULEN. *Brennstoff-Chem.* 9, 197-8(1928).—Natural humic acids are commonly differentiated into: (1) fulvic acids (H_2O sol.), (2) hymatomelanic acids (EtOH sol.) and (3) insol. acids. Merck's acidum humicum contained little fulvic acid, but a new acid was found which could be prepd. from EtOH soln. by digesting at temps. under 100° . This was named pyrohymatomelanic acid; it was completely sol. in PhOH. J. D. DAVIS

Synthesis of ephedrine and structurally similar compounds. I. A new synthesis of ephedrine. RICHARD H. F. MANSKE AND TREAT B. JOHNSON. Yale Univ. *J. Am. Chem. Soc.* 51, 580-2(1929).—A reaction, consisting in taking advantage of the differential additive capacity of the 2CO groups in arylalkyl *o*-diketones, is reported whereby it is possible to synthesize ephedrine. A mixt. of 50 cc. abs. EtOH, 7.4 g. BzAc and an alc. soln. contg. 1.6 g. MeNH₂, catalytically reduced with H (0.1 g. Pt oxide), gives 2.5-4.0 g. *dl*-ephedrine-HCl. C. J. WEST

Ultra-violet absorption of *p*-aminobenzoic esters in water solution. E. RAYMOND RIEGEL AND KENNETH W. BUCHWALD. Univ. of Buffalo. *J. Am. Chem. Soc.* 51, 484-92(1929).—The ultra-violet absorption of the H_2O solns. of *p*-H₂NC₆H₄CO₂H and of 7 of its esters has been detd. In order to assist in the discussion the ultra-violet absorption of *p*-Me₂NC₆H₄CO₂H, PhNH₂ and its HCl and HBr salts, BzOH, *p*-HOC₆H₄CO₂H, guanidine carbonate, nitroguanidine, aminonitroguanidine, stovaine, alypin, C₆H₆ and the free bases of butyn, procaine and tutocaine in H_2O soln. was also detd. The selective absorption of the *p*-H₂NC₆H₄CO₂H compds. averages 14,100, with the extremes 9700 and 15,900, while that for C₆H₆ in H_2O soln. is less than 100; hence the considerable absorption of the *p*-H₂NC₆H₄CO₂H compds. is not due to the benzenoid nucleus but rather to a hemiquinoid state. This conclusion is confirmed by a consideration of the selective absorption of the addnl. substances studied. C. J. WEST

New series of sulfonephthaleins. WILTON C. HARDEN AND NATHAN L. DRAKE Hynson, Wescott and Dunning and Univ. of Maryland. *J. Am. Chem. Soc.* 51, 562-6(1929).—By use of the proper tetrahalogenated *o*-sulfobenzoic anhydride and PhOH or *o*-MeC₆H₄OH, the following sulfonephthaleins were prepd. (the yield and *p*_H range are given): *Phenoltetrachloro*-, pink, 45%, 6.6 to 8.2 (*tetra-Br deriv.*, salmon-colored, 81%, 3.0 to 4.6); *phenoltetrabromo*-, 60%, 6.6 to 8.2 (*tetra-Br deriv.*, cream-colored, 3.0 to 4.6); *o-cresoltetrachloro*-, greenish red iridescent plates, 73%, 7.2 to 8.8 (*di-Br deriv.*, 5.2 to 6.8); *o-cresoltetrabromo*-, 82%, 7.2 to 8.8 (*di-Br deriv.*, 5.2 to 6.8); *o-cresoltetraiodo*-, 7.0 to 8.6; *dibromophenoltetrabromo*-, 5.6 to 7.2. The color changes are also given. The nature of the halogen in the *o*-sulfobenzoic acid part seems to affect the color only slightly. The replacement of 4H atoms by halogens does not materially change the useful *p*_H range of the compds. The halogenated compds. show an addnl. extremely acid range not measurable by the ordinary buffers; this range might possibly prove useful since in *N* HCl they are red shading to yellow at *p*_H in the vicinity of 2.0. They possess no apparent advantage as indicators over those now in general use. C. J. WEST

Pungent principles of ginger. V. Distillation of methylgingerol. HIROSHI NOMURA AND KENJI IWAMOTO. *Science Repts. Tohoku Imp. Univ.* 1st ser. 17, 973-84(1928); cf. *C. A.* 21, 2258, 3359.—Methylgingerol (I), m. 63.5-64°, gives an oxime, m. 85.5-86.5°. Distn. of I under ordinary pressure at 250-400° gives C₆H₁₁CHO, methylzingeronone (II) and an unsatd. ketone, methylshogaol. Distn. of I under diminished pressure gives unchanged I and II. I contains 1 HO group (reaction with MeMgI). These facts lead to the probable formula for I of (MeO)₂C₆H₃CH₂CH₂COCH₂CH(OH)(CH₂)₄Me. C. J. WEST

The production of *p*-cymene and its possibilities as a raw material in the chemical industry. G. AUSTERWEIL. *Chimie et industrie Special No.*, 568-86(April, 1928).—A review. A. PAPINEAU-COUTURE

Synthesis of 6-hydroxypiperonylic acid and incidental compounds. MARSTON T. BOGERT AND FRANK R. ELDER. Columbia Univ. *J. Am. Chem. Soc.* 51, 532-9(1929).—Directions are given for the prepn. of 6-nitropiperonal (I) in 70% yields. 6-Nitropiperonylidenediurethan, pale yellowish green, m. 207-8° (all m. ps. cor.); the yield is only 10% because of difficulty of purification. I gives an oxime, m. 201-3°, reduced to the 6-NH₂ deriv., m. 182-3°. Depending upon the time of heating the NH₂ deriv. gives a *mono-Ac deriv.*, m. 215-7° (10-12 min.) or a *di-Ac deriv.*, m. 146-7° (1 hr.). I may be reduced to the 6-NH₂ deriv. by FeSO₄ and NH₄OH in 60% yield; oxidation of the Ac deriv. gives 6-acetamidopiperonylic acid, m. 124-5°; *Me ester*, m. 183-4°. Through the diazo reaction there results the *Me ester*, m. 99-100° (*Ac deriv.*, m. 97-8°), of 6-hydroxypiperonylic acid, m. 211-2° (*Ac deriv.*, m. 155.5-6.5°); FeCl₃ gives a deep blue color. C. J. WEST

Syringic acid and its derivatives. MARSTON T. BOGERT AND BERNARD B. COYNE. Columbia Univ. *J. Am. Chem. Soc.* 51, 569-76(1929); cf. C. A. 13, 2032.—Modifications of the method of prepn. of trimethylgallic acid are given; also for its demethylation by concd. H_2SO_4 to syringic acid (I). Nitration of the Ac deriv. of I in Ac_2O with fuming HNO_3 at -5° gives 82% of *nitroacetylsyringic acid*, m. 190° (cor., decompn.); *Me ester*, m. 107.5° . Heating with 5% HCl gives *nitrosyringic acid*, m. 218° (cor., decompn.) (78% yield). Reduction with SnCl_2 and HCl gives 59% of *aminosyringic acid* (II), m. 169° , isolated as the *HCl salt*, m. 185° (decompn.); *Me ester*, m. 217° (65% yield). II in Ac_2O with a trace of AcONa gives 78% of the *acetanthranil of acetylsyringic acid*, m. 169° ; evapn. of the aq. soln. gives *acetamidoacetylsyringic acid*, m. 193° ; *Me ester*, m. 154° . Reduction of the NO_2 deriv. with Sn and HCl gives 78% of *3-amino-2,6-dimethylpyrogallol-HCl*, m. 198° (decompn.); *Bz deriv.*, m. 158.3° . *Methyleneaminosyringic acid*, m. 195° (decompn.) (75% yield).

C. J. WEST

Constitution of isocampholic acid. II. JULIUS V. BRAUN AND ALBRECHT HEYMONS. Univ. Frankfurt a. M. *Ber.* 61B, 2276-80(1928); cf. C. A. 22, 2935.—In CH_2CHMe

their 1st paper v. B. and H. gave the preference to the formula

for isocampholic acid (I) because their recently developed PCl_5 method indicated that I contains a CH_2 residue adjacent to the CO_2H group. As, however, Rupe and Briellmann had obtained in the oxidation of I small quantities of camphoric acid and Lipp had observed slight differences in the m. ps. of derivs. of I and of α -campholanic acid, which certainly has the above structure, it seemed important to discover a 2nd independent method of establishing the structure of I. When an acid RCO_2H is converted through its ester into the alc. RCH_2OH and the corresponding bromide is condensed with NMe_3 to the quaternary salt $\text{RCH}_2\text{NMe}_3\text{Br}$ and the corresponding quaternary base is subjected to a Hofmann cleavage, the resulting olefin will have the structure $\text{R}'\text{CH}=\text{CH}_2$ if in R there was a CH_2 residue adjacent to the CO_2H group and, in such a case only, will yield on oxidative degradation an aldehyde and the next lower homologous acid: $\text{RCH}_2\text{CO}_2\text{H} \rightarrow \text{RCH}_2\text{CH}_2\text{OH} \rightarrow \text{RCH}_2\text{CH}_2\text{Br} \rightarrow \text{RCH}_2\text{NMe}_3\text{Br} \rightarrow \text{RCH}=\text{CH}_2 \rightarrow \text{RCHO} \rightarrow \text{RCO}_2\text{H}$. Application of this method to I fully confirmed the conclusions reached in the earlier paper. β -[2,2,3-Trimethylcyclopentyl]ethyl alc. (somewhat more than 50% from the Et ester of I with Na and alc.), liquid of pleasant odor, b_{14} $109-12^\circ$, d_4^{20} 0.9046, n_D^{22} 1.4591, gives with 66% HBr at 125° about 90% of the *bromide*, faintly yellow, has only a faint odor, b_{12} 102° . With NMe_3 in C_6H_6 at 100° the *bromide* gives in 14 hrs. 83% of [β -(2,2,3-trimethylcyclopentyl)ethyl]trimethylammonium *bromide*, somewhat hygroscopic, decomp. 277° ; *chloroplatinate*, orange, decomp. 244° . The hydroxide on distn. yields chiefly [β -(2,2,3-trimethylcyclopentyl)ethyl]dimethylamine (II) and only very little [2,2,3-trimethylcyclopentyl]ethylene (III), but if, before the distn., the watery residue from the evapn. of the hydroxide is treated with 3-4 mols. KOH the yield of III is increased to about 40% and somewhat more than 50% II is obtained. II, liquid of basic odor, b_{14} $94-5^\circ$; *picrate*, red-yellow, m. $100-11^\circ$; *HCl salt*, m. 224° . III, b. $155-6^\circ$, has an odor which is rather strong but hardly reminiscent of terpenes, d_4^{20} 0.8024, n_D^{25} 1.4439. On ozonization in 10% AcOH III yields chiefly 2,2,3-trimethylcyclopentane-1-aldehyde, liquid of pleasant odor with pronounced camphor aroma, b_{14} $75-7^\circ$, d_4^{19} 0.9158, n_D^{20} 1.4486 (*semicarbazone*, m. 188°), and a small quantity of the acid (*norisocampholic acid*) (readily obtained from the aldehyde in Na_2CO_3 with H_2O_2), b_{12} 130° , d_4^{16} 0.9995, n_D^{19} 1.4587 (*chloride*, b_{11} 85° ; *ethylamide*, m. $68-9^\circ$).

C. A. R.

Phenylcamphor. H. RUPE AND A. WIRZ. *Verhandl. Naturforsch. Ges. Basel* 38, 164-87(1927).—By the action of PhMgBr on camphorquinone, only 1 keto group is attacked, yielding *phenylhydroxycamphor* (I or II), m. $78-9^\circ$, b_{14} $184-7^\circ$, $[\alpha]_D^{20}$ 7.96°

in C_6H_6 (*Me ether*, b_{10} $161-3^\circ$; *Et ether*, b_{10} $165-6^\circ$, d_4^{20} 1.0600, n_D^{20} 1.5284). The possi-

bility of formulation as $\text{C}_6\text{H}_4 \begin{array}{c} \text{C.OH} \\ \diagup \quad \diagdown \\ \text{C} \\ \diagdown \quad \diagup \\ \text{C.OPh} \end{array}$ $\text{C}_6\text{H}_4 \begin{array}{c} \text{CO} \\ \diagup \quad \diagdown \\ \text{C} \\ \diagdown \quad \diagup \\ \text{CHOPh} \end{array}$ is considered and rejected. The cycloacetal formulation for hydroxycamphor is not approved. Camphorquinone and phenylhydroxycamphor show abnormal rotation dispersion. The rotation dispersion constns. of phenyl camphor deviate markedly from those of the alkylcamphors. Phenylchlorocamphor, $\text{C}_6\text{H}_4 \begin{array}{c} \text{CO} \\ \diagup \quad \diagdown \\ \text{C} \\ \diagdown \quad \diagup \\ \text{CClPh} \end{array}$, from phenylhydroxycamphor and PCl_5 in 36–48 hrs. at the ordinary temp., m. 129° ; it is reduced by Zn dust and AcOH, or by hydrogenation in a mixt. of alc., EtOAc, and water in presence of a Ni catalyst, to *phenylcamphor*, $b_{10} 172-4^\circ$, m. $45-6^\circ$, $[\alpha]_D^{20} 184.42^\circ$ or 180.45° in C_6H_6 . *Phenylborneol*, $\text{C}_6\text{H}_4 \begin{array}{c} \text{CHOH} \\ \diagup \quad \diagdown \\ \text{C} \\ \diagdown \quad \diagup \\ \text{CHPh} \end{array}$, obtained from phenylhydroxycamphor, Na and boiling alc., m. $139-40^\circ$, $[\alpha]_D^{20} -76.19^\circ$ in C_6H_6 (isomeride from petroleum, $b_{10} 179-82^\circ$, $d_4^{20} 1.0897$, $[\alpha]_D^{20} 20.43^\circ$). Treatment of this with HCO_2H or H_3PO_4 affords *phenylbornylene*, $\text{C}_{18}\text{H}_{14} \begin{array}{c} \text{CH} \\ | \\ \text{CPh} \end{array}$, $b_{11} 135-41^\circ$, $d_4^{20} 0.9767$, $n_D^{20} 1.54167$, $[\alpha]_D^{20} 40.56^\circ$, or $d_4^{20} 0.9865$, $n_D^{20} 1.54445$, $[\alpha]_D^{20} 8.33^\circ$, resp. B. C. A.

Stereoisomerism of diphenyl compounds. II. Resolution of 3,3'-diaminodimesityl. WENDELL W. MOYER AND ROGER ADAMS. Univ. of Illinois. *J. Am. Chem. Soc.* 51, 630-8(1929); cf. *C. A.* 22, 3886.—Directions are given for the prepn. of dimesitylene (I) in 22% yield from bromomesitylene through the Grignard reagent with CuCl_2 . Fuming HNO_3 quantitatively converts I into the *tetra-NO₂ deriv.*, m. $270-1^\circ$; by partial reduction a mixt. of NH_2 derivs. is formed. I and Br in CCl_4 give a 3,3'-*di-Br deriv.*, m. $112-3^\circ$ (63% yield); an attempt to prep. a mono-Grignard reagent was not very successful and the action of CO_2 gave no definite product. I and AcNO_2 in CCl_4 at $30-40^\circ$ give 98% of the 3,3'-*di-NO₂ deriv.*, m. $162.5-3.5^\circ$ (cor.); nitration in hot AcOH or in cold CCl_4 gives a mixt. of NO_2 derivs.; nitration with KNO_3 in H_2SO_4 gives a mixt., from which the *tetra-NO₂ deriv.* was isolated. Reduction with Zn and HCl gives 61% of the 3,3'-*di-NH₂ deriv.* (II), m. $206-7^\circ$ (*di-Ac deriv.*, m. $303-4^\circ$). *d-II*, m. $203.5-4.5^\circ$ (cor.), $[\alpha]_D^{20} 12.0^\circ$ (0.1907 g. in 20 cc. 0.3 N HCl), 42.3° (0.2456 g. in 20 cc. Me_2CO), is obtained by pptn. of the *d-camphorsulfonic acid salt*, crystg. with H_2O , m. $186-8^\circ$ (anhyd.), $[\alpha]_D^{20} 32.4^\circ$ (0.2255 g. in 20 cc. 95% EtOH); *Ac deriv.*, m. $312-3^\circ$ (cor.), $[\alpha]_D^{20} 30.8^\circ$ (0.2370 g. in 20 cc. abs. EtOH). The final mother liquors of the resolution, on treatment with NH_3 , give *l-II*, m. $203-4^\circ$ (cor.), $[\alpha]_D^{20} -41.5^\circ$ (0.2265 g. in 20 cc. Me_2CO); *Ac deriv.*, m. $311-3^\circ$, $[\alpha]_D^{20} -30.4^\circ$ (0.2300 g. in 20 cc. abs. EtOH). *d-II* is only slightly racemized after boiling with EtOH-KOH for 5 hrs. or with concd. HCl for 9 hrs. *Nitroiodomesitylene*, buff., m. $96-7^\circ$ (72% yield through the diazo reaction); no definite compd. could be obtained from the reaction product with Cu. These are the 1st Ph_2 derivs. resolved with the 2,6,2',6'-positions, all occupied by the same group. This lends support to the mech. theory for explaining the optical isomerism in certain Ph_2 compds. C. J. WEST

Diphenic acid series. III. H. W. UNDERWOOD, JR., AND L. A. CLOUGH. Mass. Inst. Tech. *J. Am. Chem. Soc.* 51, 583-7(1929); cf. *C. A.* 18, 3186. When Me, Et, Me_2 and Et_2 diphenate were heated with Ac_2O , each ester remained unchanged. Diphenamic acid (30 g.), 60 g. AcOH and 60 g. Ac_2O , heated at 145° for 1 hr., give 18.2 g. diphenimide, m. 219° and 3.8 g. 1-cyanobiphenyl-10-carboxylic acid, m. 168° , the latter being sepd. by its soly. in Na_2CO_3 . The diamide of diphenic acid, through the loss of 2 mols. H_2O , gives 2,2'-dicyanobiphenyl, m. 172° . *p,p'*-Dibromodiphenic acid yields an anhydride, m. $304-5^\circ$. Bischoff and Adkins (*C. A.* 17, 2283) obtained an amorphous substance by condensing diphenic anhydride with $m\text{-C}_6\text{H}_4(\text{OH})_2$ at $135-50^\circ$ with ZnCl_2 . The material is apparently identical with that secured by working at 175° ; it contains resorcinoldiphenic (I) and an amorphous condensation product derived from diphenyleneketone-4-carboxylic acid. The m. p. of I apparently changes when the compd. is heated or allowed to stand for a long time. Solus. of pure I in aq. NaOH do not show marked fluorescence. C. J. WEST

Preparation of certain chloro and bromo derivatives of 2,4-dihydroxydiphenylmethane and -ethane and their germicidal action. EMIL KLARMANN AND JOHN VON WOWERN. Lehn and Fink, Inc., Bloomfield, N. J. *J. Am. Chem. Soc.* 51, 605-10

(1929).—4'-Chloro-2,4-dihydroxydiphenylmethane, m. 80.4°, results in 55% yield from $m\text{-C}_6\text{H}_4(\text{OH})_2$, $p\text{-ClC}_6\text{H}_4\text{COCl}$ and AlCl_3 in PhNO_2 or in 33% yield by the reaction of $m\text{-C}_6\text{H}_4(\text{OH})_2$ and $p\text{-ClC}_6\text{H}_4\text{CN}$ with ZnCl_2 and HCl , decompn. of the imide HCl with boiling H_2O and reduction of the ketone (m. 155°) with Zn and HCl . The 4'-Br deriv., prepd. by the 2nd method in 45% yield, m. 96°; the intermediate ketone m. 169°. 5-Chloro-2,4-dihydroxydiphenylmethane, m. 122°, results in 51% yield from 2,4-(HO) $_2\text{C}_6\text{H}_3\text{CH}_2\text{Ph}$ and SO_2Cl_2 in Et_2O ; 5-Br deriv., m. 122.4° (71% yield). 5-Chloro-2,4-dihydroxydiphenylethane, m. 136.7° (40% yield); 5-Br deriv., m. 152.1°. Halogenation greatly increases the germicidal efficacy of these compds. against *B. typhosus* and *Staph. pyog. aureus*. Some interesting observations are made regarding reduction of the germicidal efficacy of these substances by "org. matter." The substances may be regarded as general disinfectants rather than specifics.

C. J. WEST

α -Chloronaphthalene. II. Nitration. P. FERRERO AND C. CAFLISCH. Univ. Geneva. *Helv. Chim. Acta* 11, 795-812(1928).—Nitration of $\alpha\text{-C}_{10}\text{H}_7\text{Cl}$ gives a mixt. of the 1,4-, 1,5- and 1,8-derivs. By moderate nitration (low nitration temp., H_2SO_4 at 66° BÉ, HNO_3 d. 1.4, small excess of H_2SO_4), the 1,4- and 1,5-derivs. are predominant. The 1,8-deriv. requires hot reagents, fuming HNO_3 and an important excess of H_2SO_4 to be the principal reaction product. The relative proportions of the 1,4- and the 1,5-derivs. are dependent upon the method of nitration. If the temp. is allowed to rise after the reagents have been mixed, formation of the 1,4-compd. is favored; sometimes the 1,5-isomer is then totally absent. By adding HNO_3 to the mixt. of $\text{C}_{10}\text{H}_7\text{Cl}$ and H_2SO_4 , formation of 1,5-isomer is favored; by adding H_2SO_4 last, it does not form at all. If the nitration is done without special precautions, the relative amounts will be 50% of the 1,4-compd., 10% of the 1,5-compd. and 40% of the 1,8-compd. It has been verified that a 10% glycolic soln. of NH_3 will only react with the 1,4-compd., yielding the amine. Sulfonation with $\text{H}_2\text{SO}_4\text{-H}_2\text{O}$ at 95° for 12 hrs. attacks the 1,8-compd. chiefly, the 1,4-compd. very little and the 1,5-compd. not at all.

ALBERT L. HENNE

Chlorodecalin. P. FERRERO AND M. FEILMANN. Univ. Geneva. *Helv. Chim. Acta* 11, 103-116(1928). Monochlorodecalin is prepd. by atomization of decalin with a Ce current. The halogen is relatively reactive, being easily replaced by a OH group, with formation of decalol. Treatment with NH_4OH does not yield the amine, but decalol. Condensation with amines does not succeed. Octalin and decalol are the products obtained. The Friedel and Crafts condensation is successful with C_6H_6 and PhMe ; it does not give any results with substituted hydrocarbons. Phenyl-decalin obtained by the above method, cannot be used in the phthalic condensation; resin is formed. A study of the chlorination of $\text{C}_{10}\text{H}_{18}$ in soln. shows that the concn. has no effect, but that the nature of the solvent has an enormous importance. A com. method of prepn. of $\alpha\text{-C}_{10}\text{H}_{17}\text{Cl}$ has thus been found, the details of which will be disclosed later on.

ALBERT L. HENNE

Transannular anionotropic migrations. JAMES WILFRED COOK. *J. Chem. Soc.* 1928, 2168-2170. Colorless forms of derivs. of 1,5-dichloro-9-benzylanthracene have a structure of the general type I, while the colored forms are of type II.

The change I to II is a mobile anion tautomerism, since: (a) the order of mobility ($\text{Br} > \text{OAc} > \text{OH}$ or OR) is identical with that found by Burton and Ingold for another system and (b) prototropic and anionotropic changes can be effected by the action of OH and H^+ ions resp.

Thus 1,5-dichloro-10-hydroxy-9-benzylidene-9,10-dihydroanthracene is converted into 1,5-dichloro-9-benzylanthrone by boiling with alc. NaOH . The conversion of a new geometrical isomeride of 1,5-dichloro-10-ethoxy-9-benzylidene-9,10-dihydroanthracene (obtained from 1,5-dichloroethoxyanthrone and PhCH_2MgCl followed by dehydration of the resulting dihydroanthranol) into the $\alpha\text{-EtO}$ compd. by HCl in alc. was slow and incomplete. Replacement of EtO by Br gave a mono-Br deriv. identical

with the monobromination product of 1,5-dichloro-9-benzylanthracene. This inversion of geometrical configuration is considered to pass through a form of type II. Attempts to oxidize compds. of type I to the corresponding anthrones are described. The mobile H was fixed by replacement with Ph: 1,5-dichloro-9-benzyl-10-phenylanthracene gave a reactive *mono-Br deriv.*, m. 179–80°, but the *HO*, m. 189–91°, and *EtO-deriv.*, m. 173–4° (obtained, resp., by treatment with aq. Me₂CO and EtOH in the presence of CaCO₃), were of the "yellow" type, therefore probably like II. 1-Chloro-9-benzylanthracene, m. 119–20° (the corresponding 1-chloro-9-hydroxy-9-benzyl-9,10-dihydroanthracene, m. 126–7°) and 4-chloro-9-benzylanthracene, m. 120°, were prepd. from the appropriate chloro-9-anthrone (obtained by reduction of chloroanthraquinones with Al and H₂SO₄). The former when brominated gave an unstable dibromide, which decompd. into a mixt. of 30% of 1-chloro-10-bromo-9-benzylanthracene (type II), m. 160°, and 70% of benzylidene compd. of type I, m. 151–3°. From the latter, compds. of type I and II were obtained where X = OH, OAc or OR. Thus the action of aq. Me₂CO and CaCO₃ gave 1-chloro-10-hydroxy-9-benzylidene-9,10-dihydroanthracene, m. 185°, acetylation of which gave the 10-AcO compd., m. 151–3°. MeOH in the presence of CaCO₃ gave the 10-MeO compd., m. 129–30°. This last compd. undergoes isomerization when treated with HCl in MeOH, and gives the "yellow" form (type II), m. 157–8°. 4-Chloro-9-benzylanthracene gives an unstable di-Br deriv. leading to reactive 4-chloro- ω -bromo-9-benzylanthracene, m. 165–6° (ω -pyridinium bromide, m. 220–5° (decompn.), after sintering at 215°), which passed into type II with ease, aq. Me₂CO and CaCO₃ giving yellow 4-chloro- ω -hydroxy-9-benzylanthracene, m. 98–100°, acetylation of which gave the ω -AcO compd., m. 129–30°, while MeOH and EtOH in the presence of CaCO₃ gave the ω -MeO compd., m. 144° (also formed by methylation of the ω -HO-compd. with MeOH + HCl), and the ω -EtO homolog, m. 135–7°, resp. The difference between the 1- and 4-Cl derivs. of 9-benzylanthracene are ascribed to steric effects of the α -Cl atom. The ω -MeO compd. gave an unstable dibromide which spontaneously decompd. into BzH and 4-chloro-9-bromoanthracene. The latter product is stable in the presence of an excess of Br. 1-Chloro-9-bromoanthracene was not isolated from the product of thermal decompn. of the dibromide of 1-chloro- ω -methoxy-9-benzylanthracene, only 1-chloro-9,10-dibromoanthracene being obtained. These results are attributed to the steric effect of the α -Cl atom on the assumption that bromination is preceded by 9,10-addn. of Br. Only 4-chloro-9-bromoanthracene was isolated from the action of an excess of Br on 1-chloro-10-bromo-9-benzylanthracene.

ALBERT L. HENNE

Condensation of phthalic anhydride with *o*-dichlorobenzene. MUNENARI TANAKA AND NAOZO TANAKA. Central Lab. Dairen. *Bull. Chem. Soc. Japan* 3, 286–7 (1928) — *o*-C₆H₄Cl₂ condenses with C₆H₄(CO)₂O in the presence of AlCl₃. If the condensation is carried out at 115°, 3',4'-dichlorobenzophenone-2-carboxylic acid is obtained, while at 150°, or at 130° under pressure, 2,3-dichloroanthraquinone is obtained. Correcting a paper previously given, it is stated that *o*-ClC₆H₄OH and C₆H₄(CO)₂O in the presence of H₂BO₃ and H₂SO₄ give alizarin and 1-hydroxy-2-chloroanthraquinone by heating 1 hr. at 240° and 0.5 hr. at 255°, but only purpurin by heating for 3 hrs. at 255°.

ALBERT L. HENNE

Dehydrating action of Japanese acidic earth in the anthraquinone series. MUNI HARI TANAKA AND SUSUMU WATANABE. Central Lab. Dairen. *Bull. Chem. Soc. Japan* 3, 288–9 (1928).—The C₆H₄(CO)₂O condensation is tried with Japanese earth replacing the customary AlCl₃. Hydroquinone reacts easily at 260°; pyrocatechol yields only a limited quantity of hystazarin and alizarin; pyrogallol gives no anthraquinonic deriv., but gallein; α -naphthol gives α -hydroxynaphthacenequinone.

ALBERT L. HENNE

Action of aromatic Grignard reagent on methylsuccinimide. Synthesis of 2,5-diphenyl-1-methylpyrrole. R. LUKES AND V. PRELOG. *Chem. Listy* 22, 244–51 (1928).—*N*-Methylsuccinimide reacts with PhMgBr to yield 2-hydroxy-2-phenyl-1-methylpyrrolid-2-one, m. 139–41° (phenylhydrazone, m. 186°), and 2,5-diphenyl-1-methylpyrrole, m. 204°, b₁₂ 225–35°. Where the Grignard reagent is not present in excess and the time of reaction is short, the former product predominates; otherwise the latter is the main product. The former substance on acid hydrolysis yields MeNH₂ and BzCH₂CH₂CO₂H and on distn. under reduced pressure gives water and 5-phenyl-1-methylpyrrolone, m. 59°, b, 150–65°.

B. C. A.

Alkylation and acylation of thiophene in the presence of tin tetrachloride. G. STADNIKOV AND I. GOLDFARB. Lab. f. Kohlen-Forschung, Moskau. *Ber.* 61B, 2341–2 (1928); cf. *C. A.* 23, 130.—Further study of the reaction of thiophene (I) with acid chlorides in the presence of SnCl₄ showed that the yield of ketones depends to some

extent on the solvent. In new syntheses of acetothienone (II) in benzene (b. 120–40°) the yields varied between 50 and 58%. C_6H_6 , however, gives good yields, so the method may be used for the estn. of I in crude C_6H_6 . Alc. residues can also be introduced into the I nucleus in the presence of $SnCl_4$. II, b_{760} 213.5–4.5°, is obtained in 96% yield from 16.8 g. I and 15.6 g. $AcCl$ in 170 g. C_6H_6 with 52 g. $SnCl_4$ and benzothienone, m. 55°, in 82.5–92% yield with $BzCl$. The reaction of I with Ph_2CHCl , which is formed from Ph_2CHOEt and $SnCl_4$, is so energetic that it may result in the formation of resinous products, but by working cautiously in CS_2 there can be obtained diphenylthienylmethane, m. 65°, and 50% of dibenzohydrylthiophene (ω, ω' -tetraphenylthioxene) (III), m. 85–5.5°, very sensitive to light, mol. wt. in C_6H_6 394–6. I reacts with Ph_2CHCl incomparably more rapidly than does C_6H_6 , so the synthesis can be carried out in C_6H_6 without the simultaneous formation of appreciable quantities of Ph_2CH . With $CrO_2 \cdot AcOH$, III gives Ph_2CO (yield, 78.7% as the oxime). C. A. R.

α, α' - and α, α' -Disubstituted α, α' -dihydro- β, β' -benzofurans. FELIX SEIDEL. Univ. Tübingen. Ber. 61B, 2267–76(1928).—Guyot and Catel obtained from $PhMgBr$ and phthalide a substance which they believed to be α, α' -diphenyl- β, β' -benzo- α, α' -dihydrofuran (I) and from α -phenylphthalide an isomer which they considered to be the sym. α, α' -diphenyl- β, β' -benzo- α, α' -dihydrofuran (II). The 2 substances are very similar to each other, both are colorless and they have nearly the same m. p. (93° and 96°, resp.), and it seemed possible that they might be identical, the 1 form passing into the other by a kind of pinacolin or retropinacolin rearrangement; another possibility was that the substance was neither I nor II but *o*-benzoyldiphenylmethane (III). Further to characterize I, prepd. according to G. and C., attempts were made to make it react with the most varied reagents. It is extraordinarily stable towards reducing agents and does not condense with $PhNHNH_2$, $BzNHNH_2$ or $p-O_2NC_6H_4NH_2$. With oxidizing agents it gives substances strikingly different from those obtained with II and III; $K_2Cr_2O_7$ and $KMnO_4$ in $AcOH$ give α, α' -diphenylphthalide (IV); dil. HNO_3 yields as a stable intermediate product α, α' -diphenyl- β, β' -benzo- α, α' -dihydro- α' -hydroxyfuran ether, $[C_6H_4 \cdot CPh_2 \cdot O \cdot CH]_2O$ (V), which with $K_2Cr_2O_7$ and $KMnO_4$ like-

wise gives IV. V is remarkably stable towards sapon. agents; it is unchanged by long boiling with HCl or dil. H_2SO_4 in $AcOH$ and is attacked only by alc. HCl at 135°, but at the same time is reesterified to the compd. VI; the hemiacetal could not be isolated. If the sapon. is carried out in glacial $AcOH$ there are formed amorphous, dark brown decompn. products from which no cryst. compd. could be isolated. It is very difficult to obtain II according to the meager directions in the literature. It readily yields *o*- $C_6H_4Bz_2$ with $K_2Cr_2O_7$ and dil. HNO_3 , in the latter case without forming an intermediate product. II is unchanged by N_2H_4 or $PhNHNH_2$. The usual ketone syntheses cannot be used for the prepn. of III. *o*- $IC_6H_4CH_2Ph$ and BzI do not react with each other in the presence of Ag, Na and "Naturkupfer," nor does $PhCH_2C_6H_4MgI$ react with BzI , or $(PhCH_2C_6H_4CO_2)_2Ba$ with $BzOH$ at 310° under 15 mm. *o*- $PhCOC_6H_4Br$, $PhCH_2Br$ (or $PhCH_2Cl$) and Cu give only (*o*- BzC_6H_4)₂. $PhMgBr$ and *o*- $PhCH_2C_6H_4CN$, however, give the imine $PhCH_2C_6H_4CPh:NMgBr$ (VIII) which with acids yields III. III normally forms a phenylhydrazone (VIII) and is oxidized by dil. HNO_3 directly to *o*- $C_6H_4Bz_2$. I, II and III are therefore entirely distinct compds. which cannot be converted into each other. V (3.0 g. from 5.0 g. I boiled 1 hr. in 50 cc. concd. HNO_3 and 100 cc. H_2O), m. 259–60°, mol. wt. in $C_{10}H_8$ 560.4–581.8. α, α' -Diphenyl- β, β' -benzo- α, α' -dihydro- α' -hydroxyfuran Et ether (VI), m. 97°, mol. wt. in $C_{10}H_8$ 302.7. II (5.7 g. from 9.6 g. $PhBr$, 2.4 g. Mg and a particle of I in 60 cc. cold Et_2O slowly treated with 6.3 g. phenylphthalide in 150 cc. C_6H_6 , boiled 30 min., cooled, decompd. with aq. NH_4Cl , sepd. from the aq. layer, washed with H_2O , treated with 3% $Na-Hg$, freed from the Et_2O by distn., treated with $MeOH$ and boiled 35 hrs. with frequent stirring), m. 93–5°. III, b_{16} , 220–5°, very faintly yellow liquid crystg. after 5 days in needles, m. 47–50°. VIII, m. 139°. *o*- $PhCH_2C_6H_4NH_2 \cdot HCl$, m. 180°, is obtained in 4.7 g. yield from 8.5 g. *o*- $ClH_2NC_6H_4CH_2Cl$ refluxed 1 hr. in C_6H_6 with 15 g. $AlCl_3$; diazotized in concd. HCl and treated with aq. KI at room temp. it gives *o*-iododiphenylmethane, b_{16} , 175–80°. C. A. R.

Benzidine rearrangement in the heterocyclic series. II. PRAFULLA KUMAR BOSH AND BIJON KUMAR SEN. J. Indian Chem. Soc. 5, 643–55(1928); cf. C. A. 22, 1159–B. and S. have extended B.'s work on benzidine and semidine rearrangements in the heterocyclic series. By condensing 1-*o*-tolylthiosemicarbazide (I) or the *m*-compd. (II) with halogenated ketones (III), heterocyclic hydrazo compds. (IV) are formed which undergo benzidine rearrangement. IV give characteristic color reactions with concd. H_2SO_4 , are affected by light or air, and are oxidized to corresponding azo derivs.

by FeCl_3 . IV are transformed into the isomeric bases when treated with boiling dil. HCl . Condensation of 1-*p*-tolylthiosemicarbazide (V) with III gives products which on b. with dil. HCl split off NH_3 , and are converted into thiazoles of the type $\text{CR}:\text{CH}:\text{S}:\text{CO}:\text{NNHC}_6\text{H}_4\text{Me}$. I, m. $163-4^\circ$ is prepd. by heating *o*- $\text{MeC}_6\text{H}_4\text{NHNH}_2$

and KSCN in alc. on the water bath for 12 hrs. I and PhCOCH_2Br (VI) in alc. at room temp., give 2-*o*-tolylhydrazino-4-phenyl-1,3-thiazole (VII), m. $175-80^\circ$ (decompn.); *Ac deriv.*, m. 152° . Oxidation of VII with FeCl_3 gives the corresponding azo deriv. (VIII), orange crystals, m. 110° , which dyes wool yellow and gives deep blue color with concd. H_2SO_4 . Reduction of VIII with Zn dust and dil. AcOH gives VII. Oxidation of 2-phenylhydrazino-4-phenyl-1,3-thiazole (see C. A. 22, 1158) with FeCl_3 gives 2-benzeneazo-4-phenyl-1,3-thiazole, orange crystals, m. 117° . Similarly, 2-phenylhydrazino-4-*p*-tolyl-1,3-thiazole gives the corresponding azo compd., orange crystals, m. 161° , dyeing wool a deep orange; 2-phenylhydrazino-4-methyl-1,3-thiazole gives the azo compd., m. 120° , dyeing wool yellow. VII with boiling dil. HCl gives 2-amino-4-phenyl-5-*p*-amino-*m*-tolyl-1,3-thiazole, yellow needles, m. 165° ; HCl salt, m. 197° ; *picrate*, red plates, m. 227° (decompn.); *di-Ac deriv.*, m. 182° ; *chloroplatinate*, yellow crystals. I and *p*- $\text{MeC}_6\text{H}_4\text{COCH}_2\text{Br}$ (IX) gives 2-*o*-tolylhydrazino-4-*p*-tolyl-1,3-thiazole (X), m. 179° , giving a green color with concd. H_2SO_4 ; *Ac deriv.*, m. $160-1^\circ$. Oxidation of X with FeCl_3 gives the corresponding azo deriv., brick-red crystals, m. 148° . X and boiling dil. HCl give 2-amino-4-*p*-tolyl-5-*p*-amino-*m*-tolyl-1,3-thiazole, brown needles, m. 181° ; *di-Ac deriv.*, m. 208° ; HCl salt, m. 278° (decompn.); *chloroplatinate*, brown crystals, m. 201° (decompn.). I and AcCH_2Cl (XI) give 2-*o*-tolylhydrazino-4-methyl-1,3-thiazole (XII), reddish needles, m. 162° (decompn.); *Ac deriv.*, m. 96° . XII and boiling dil. HCl give 2-amino-4-methyl-5-*p*-amino-*m*-tolyl-1,3-thiazole, brown needles, m. 144° ; HCl salt, m. 261° (decompn.); *di-Ac deriv.*, m. 266° ; *picrate*, m. 247° (decompn.); *chloroplatinate*, gray crystals. II, prepd. similarly to I, reacts with VI giving 2-*m*-tolylhydrazino-4-phenyl-1,3-thiazole (XIII), m. 188° (decompn.), giving a blue color with concd. H_2SO_4 ; *Ac deriv.*, m. 145° . XIII and boiling dil. HCl give 2-amino-4-phenyl-5-*p*-amino-*o*-tolyl-1,3-thiazole, brown needles, m. 135° ; HCl salt, m. $265-70^\circ$ (decompn.); *di-Ac deriv.*, m. 235° ; *picrate*, m. 215° (decompn.). II and IX give 2-*m*-tolylhydrazino-4-*p*-tolyl-1,3-thiazole (XIV), pale brown needles, m. 191° (decompn.); *Ac deriv.*, m. 121° . XIV and boiling dil. HCl give 2-amino-4-*p*-tolyl-5-*p*-amino-*o*-tolyl-1,3-thiazole, brown needles, m. 175° ; *Ac deriv.*, m. 243° ; HCl salt, m. 247° ; *picrate*, m. 202° . II and XI give 2-*m*-tolylhydrazino-4-methyl-1,3-thiazole (XV), reddish needles, m. 135° (decompn.); *Ac deriv.*, m. 119° . XV and boiling dil. HCl give 2-amino-4-methyl-5-*p*-amino-*o*-tolyl-1,3-thiazole, m. 157° ; *Ac deriv.*, m. 236° ; HCl salt, m. 263° (decompn.); *picrate*, m. 212° (decompn.). V prepd. similarly to I, m. 174° , reacts with VI giving 2-imino-3-*p*-toluidino-4-phenyl-2,3-dihydro-1,3-thiazole (XVI), m. 193° (decompn.), blue color with concd. H_2SO_4 ; *Ac deriv.*, m. 147° . XVI and boiling dil. HCl give 2-keto-3-*p*-toluidino-4-phenyl-2,3-dihydro-1,3-thiazole, yellow plates, m. $210-1^\circ$. V and XI give 2-imino-3-*p*-toluidino-4-methyl-2,3-dihydro-1,3-thiazole (XVII), reddish needles, m. $168-9^\circ$; *p*-tolylthiocarbimide deriv., m. 143° . XVII and boiling dil. HCl give 2-keto-3-*p*-toluidino-4-methyl-2,3-dihydro-1,3-thiazole, yellow crystals, m. 177° . V and IX give 2-imino-3-*p*-toluidino-4-*p*-tolyl-2,3-dihydro-1,3-thiazole, brown needles, m. 184° (decompn.), *Ac deriv.*, m. 155° ; *p*-tolylthiocarbimide deriv., m. 152° .

FREDERICK C. HAHN

The red quinoline dye of Besthorn. HEINRICH WIELAND, OTTO HETTCH and TOSHIO HOSHINO. Bayr. Akad. Wiss., München. *Ber.* 61B, 2371-81 (1928). Although there is hardly any other structure possible for the dye (I) than that (II) proposed by Ibele, and Besthorn himself has made such a formula very probable by his investigations, it is so peculiar in having a N atom with 5 valences not polarly bound to C that the authors have attempted to secure further evidence of its correctness. In 1 of his last papers B. describes a colorless reduction product obtained by adding 6 atoms of H to I by means of Pd black and which on cautious oxidation with CrO_3 - AcOH regenerates I. If II is correct the reduction product should have the structure III. It was hoped that III might be synthesized by catalytically hydrogenating Me quinaldinate to the tetrahydro compd., sapon. this to the free acid, (IV), condensing it with α -chloroquinoline and closing the ring to form III, but the 1st step in the synthesis could not be effected. Quinaldinyll chloride and tetrahydroquinoline (V) were then condensed to the amide VI, but the VI could neither be hydrogenated, as had been intended, nor converted into I by direct oxidation. It was hoped that by protecting IV by substituting the H in the NH group and converting the substituted deriv. into the chloride the latter might be made to react with V, but the urethan (VI) gave the

of prepg. II has been subjected to careful study as his statement that short treatment of I with CH_3N_3 in Et_2O results in methylation on the N also seemed surprising. Methylation in $\text{EtOH-Et}_2\text{O}$ according to his directions gave an amorphous substance; methylation of the phenolic HO group was almost complete but the N remained chiefly secondary. With Ac_2O at room temp. most of the crude product was converted into *N*-acetylaurotelanine *O*-Me ether (IV) and only about 23% remained as a tertiary base which proved to be identical with III. Furthermore, the methylation product with MeI and KOH gave III.MeI. G.'s II was therefore a mixt. of III and I *O*-Me ether. That I on oxidation gives $1,2,3,4,5\text{-C}_6\text{H}(\text{OMe})_2(\text{CO}_2\text{H})_3$ (V) was confirmed. V does not sublime at 150° under 0.005 mm.; in open tubes it loses CO_2 at 260° and now on sublimation in a high vacuum there is obtained *m*-hemipinic anhydride. This, in connection with the other properties of I, indicates that it has 1 of the structures VI or VII. The presence of a phenanthrene nucleus was shown by subjecting the quaternary chloride of the fully methylated I to an Emden degradation and oxidizing the resulting base with HNO_3 , which yielded $1,2,3,4\text{-C}_6\text{H}_2(\text{CO}_2\text{H})_4$. When the base mixt. obtained from I and MeCHN_3 is energetically oxidized with KMnO_4 and the resulting acid mixt. is distd. in a high vacuum at such a temp. that no CO_2 is split off there is obtained MeEt ether of nor-*m*-hemipinic anhydride. It was attempted, by gentle oxidation of I, to destroy the nucleus carrying the free HO group and obtain the tetrahydroisoquinoline complex in the form of a corydaldinecarboxylic acid which on splitting off CO_2 should yield the corydaldine. The KMnO_4 oxidation apparently proceeded smoothly but the corydaldine could not be isolated from the resulting acid without deep-seated decompn. In this connection was synthesized *5,6-dimethoxy-1-keto-1,2,3,4-tetrahydroisoquinoline* (VIII) by condensing $2,3\text{-(MeO)}_2\text{C}_6\text{H}_3\text{CH}_2\text{CH}_2\text{NH}_2$ with ClCO_2Et and closing the ring in the resulting product (IX) with P_2O_5 . These results det. in the main the ring system in I except for the pyridine nucleus. Further conclusions must for the present be based on the synthesis of III by Pschorr and Gadamer. To exclude the possibility that in I there is a double bond in position 3,4, III was subjected to vigorous treatment with Sn and HCl and I to electrolytic reduction at a Pb cathode; in both cases the bases remained practically unchanged, whence it may safely be assumed that the pyridine ring is tetrahydrogenated. The results so far obtained do not permit of deciding between structures VI and VII but VI is provisionally given the preference because in isoquinoline alkaloids with a free HO group on the benzyl nucleus the HO group is generally in position 3. Barger has also shown that II and III are identical. IV (0.723 g. from 1.005 g. I), m. $188-9^\circ$. IX, sirup, b_{0.005} $140-50^\circ$ (bath temp.). VIII, m. $154-5^\circ$.

C. A. R.

Constitution of solanin. GÉZA ZEMPLÉN AND ÁRPÁD GERÉCS. Tech. Hochschule, Budapest. Ber. 61B, 2294-2300(1928).—Contrary to the statements of Heiduschka and Sieger solanin (I) can readily be acetylated. The product breaks down on short treatment with HBr in glacial AcOH, yielding 2 cleavage products: an acetylated solanidine glucoside (II) and the bromoacetyl deriv. (III) of a biose composed of galactose and rhamnose. Although the components are not cryst., their properties could be detd. with certainty. The II on acid hydrolysis yielded solanidine (IV) and glucose and the biose on iodometric oxidation gave a rhamnosidogalactonic acid (V) since on distn. with HCl the V gave large quantities of methylfurfural. Hence in I the IV must be bound to a trisaccharide, the components being arranged in the order $\text{IV} \rightarrow \text{glucose} \rightarrow \text{galactose} \rightarrow \text{rhamnose}$. The data in the literature on the compn. of I and IV vary greatly. Z. and G. obtained as the av. of several analyses values corresponding to the formula $\text{C}_{44}\text{H}_{71}\text{O}_{13}\text{N}$ for I and therefore, assuming that the 3 sugar residues are bound as a trisaccharide, to $\text{C}_{26}\text{H}_{41}\text{ON}$ for IV; direct analyses of IV.HCl also agreed with the latter formula. The I (Merck's Solanin puriss. cryst.) contained 5.35% H_2O and showed $[\alpha]_D -59.45^\circ$ in $\text{C}_6\text{H}_5\text{N}$; 50 g. with NaOAc and Ac_2O on the H_2O bath yielded about 45 g. of a *trideca-Ac deriv.* (VI) (found C 56.44-56.37, H 7.30-7.23, N 1.10-1.23%), $[\alpha]_D^{20} -34.96^\circ$ (abs. alc.), sinters 190° , m. $204-5^\circ$. II (C 59.51-59.75, H 8.03-7.91%) (22 g. from 50 g. VI in CHCl_3 , allowed to stand 1 hr. at room

$C_{37}H_{46}ON_4$, m. 260° . Similarly mesoporphyrin di-Me ester yields a *carbinol*, $C_{37}H_{48}O_3N_4$ or $C_{35}H_{44}O_3N_4$, m. 295° (cor.) from MeOH, 308° from AcOH. The *xanthoporphinogen* from mesoetioporphyrin crysts. with 1 mol. C_6H_6 easily replaced by 1 mol. H_2O . Etio-xanthoporphinogen I (*mono- and di-K and di-Na salts*) crysts. with 3 Me_2CO . *Meso-xanthoporphinogen* (*Et ester*) is intensely yellow and very hygroscopic. Nitration of etioporphyrin I with cold HNO_3 gives a *tri-NO₂ deriv.*, m. 305° (block); (HNO_3 , HCl , Cu salt, m. 313° and Fe salt). *Trinitroetioporphyrin II*, m. 246° (block), is spectroscopically identical with its isomer (HCl salt; Cu salt, m. 285° (block)). Crystallographic data (by STREINMETZ) for several etioporphyrins and the absorption spectra of a large no. of the above compds. and those of the Cu salts and hemochromogen derivs. of meso-, rhodo-, deuterio- and phylloetioporphyrins are given. II. **Rhodins and verdins.** H. FISCHER, A. TREIBS AND H. HELBERGER. *Ibid* 243-64.—In an attempt to introduce an Ac group into the porphin mol. pyrroporphyrin was treated with an excess of $AcCl$ in CS_2 and $AlCl_3$. The product isolated was *pyrro-rhodin*, $C_{31}H_{32}ON_4$, m. 280° (block), probably identical with phyllo-rhodin (cf. following abstr.). Similar treatment of mesoporphyrin gives *meso-rhodin* (I), $C_{34}H_{36}O_3N_4$, m. 297° (block). *Me ester*, m. 268° (cor.), from the *K* salt and Me_2SO_4 ; *Cu salt*; *Fe complex*, $C_{34}H_{34}O_3N_4ClFe$; *Mg complex* (*phyllin*), by the action of $MeMgI$, together with *mesoverdin*, $C_{34}H_{36}O_3N_4$, m. 298° (HCl and Cu salts). Fuming H_2SO_4 converts mesoporphyrin into I. The action of concd. $MeOH-KOH$ on I in C_6H_5N yields a *mesoverdin*, m. 308° (block). Fuming H_2SO_4 at 50° converts 1,4,6,7-tetramethyl-2,3,8-triethyl-5- β -carboxyethylporphin into a *rhodin*, $C_{33}H_{34}ON_4$ (*Cu*, *Mg* and *Fe complexes*), which on oxidation with CrO_2 and H_2SO_4 yields methylethylmaleimide. The absorption spectra of the majority of the above compds. are tabulated. The production of these rhodins from porphincarboxylic acids is due to the elimination of H_2O between the β -carboxyethyl group and either the imino or methene H in the porphin ring. Thus, monoacidic porphins yield chem. indifferent rhodins (*i. e.*, pyrro-), while diacidic porphins give acidic rhodins (meso-). III. A. TREIBS AND E. WIEDEMANN. *Ibid* 264-91. Alk. fission of pheophytin gives a mixt. of phytochlorin *e* (I), $C_{33}H_{34}O_7N_4$ or $C_{35}H_{36}O_7N_4$, and phyto-rhodin *g* (II), $C_{32}H_{32}O_8N_4$ or $C_{34}H_{34}O_8N_4$. Degradation of a mixt. of I and II with $MeOH-KOH$ at 155° in C_6H_5N gives a mixt. of pyrro- and phylloporphyrins, at $145-50^\circ$ only phyllo-; at 210° only pyrro-. Similarly I at 155° affords pyrro- (10%) and phyllo-(40%), while II at 165° yields a small quantity of pyrroporphyrin (III) III (*Me ester*, m. 241° (cor.)) (*Fe salt*, *Cu* and *Mg salts*), when treated with Br in $AcOH$, furnishes a perbromide, which on treatment with Me_2CO passes into *bromopyrroporphyrin* (*Me ester*, m. 261° (cor.)). Wilstätter's phylloporphyrin contains III; pure phylloporphyrin (IV), $C_{31}H_{34}O_3N_4$ (*Me ester*, m. 235° (cor.)) (*Fe salt*); (*Cu salt*), yields a *Br deriv.* (V) (*Me ester*), which on oxidation with CrO_2 and H_2SO_4 yields methylethylmaleimide, bromocitraconimide and hematinic anhydride. When IV or V is heated with $MeOH-KOH$ at $190-200^\circ$ in a sealed tube, III is obtained. Absorption spectra of most of the above compds. are tabulated. Phyllo- and pyrro-rhodins are shown to be identical. C. J. WEST

From cholesterol to the bile acids. A. GRIGAUT. *Bull. soc. chim. biol.* 10, 937-71 (1928).—A review is given of the work of Windaus and Wieland and their collaborators on the structure and relationships of cholesterol, coprosterol and their derivs. and of the bile acids. L. C.

Structure of thymonucleic acid. P. A. LEVENE AND E. J. LONDON. Rockefeller Inst. *Science* 68, 572-3(1928).—Plant nucleic acid is regarded as a tetranucleotide, each nucleotide being composed of H_3PO_4 , a sugar (ribose) and a N component. For thymonucleic acid an analogous structure is suggested, each complex being called a nucleoside. One such nucleoside has been isolated in cryst. form. L. and L. wish to reserve to their lab. work on this substance. L. W. RIGGS

The catalytic hydrogenation of hemins and porphyrins. RICHARD KUHN AND CARL SEYFFERT. *Ber.* 61B, 2509-16(1928).—That hemin (I) in aq., alk. or C_6H_5N

alysts, and that the addn. of H ceases affirmed (cf. *C. A.* 21, 2702); the amt. of for 1 mol. and any appreciable variation

from this is caused by an unsatisfactory catalyst or by the quality of I; some samples of I, although nicely cryst. could not be hydrogenated under otherwise favorable conditions. The time necessary for the absorption was shortened to 1.75 hrs. when 0.05 g. Pd on Norit was used with 4.5 g. I. That the reduction product does not contain mesohemin (II) was shown spectroscopically. When I is subjected to a very energetic reduction (PtO in $C_6H_{11}N-CHCl_3$) II is formed and the reason this could not be duplicated by Fischer and Walter (cf. *C. A.* 22, 1784) was due to their use of C_6H_5N as the

solvent. It was found that mesoporphyrin (III) and its di-Me ester (IV) can be hydrogenated with the same catalysts that are suitable for hydrogenation of I into dihydrohemin; these reduction products when isolated were found identical in cryst. form, absorption spectra and Zerevitinov no. with the resp. starting products because the H which was added during the reaction is so labile that during the operations of isolation atm. O_2 caused the formation of the original starting products. Mesoporphyrin-HCl in AcOH with PtO and H_2 becomes colorless after absorption of 5 mols. H_2 as does mesoporphyrin after absorption of 2-3 mols. H_2 ; both reductions absorb O_2 rapidly with regeneration of starting product; protoporphyrin di-Me ester (V) similarly absorbs about 5 mols. H_2 with the formation of a leuco compd.; but this leuco compd. is oxidized by the atm. O_2 to IV; thus the following conversion can be made with theoretical yields: $V \rightarrow$ mesoporphyrinogen \rightarrow IV; this furnishes a useful method for the prepn. of IV from I since protoporphyrin is obtained by removal of Fe from I.

N. A. LANGE

Cerebrosides. IX. Cerebronic acid. E. KLENK. Univ. Tübingen. *Z. physiol. Chem.* **179**, 312-9(1928); cf. *C. A.* **23**, 603.—By the reduction of cerebronic acid to lignoceric acid the necessary evidence is now supplied for establishing the relationship between lignoceric, nervonic, cerebronic and α -hydroxynervonic acids, the 4 fatty acids of cerebrosides. Instead of being a C_{26} acid as was formerly supposed, cerebronic is a C_{24} acid and fits into the theory proposed by Emil Fischer that higher fatty acids are predominantly multiples of C_8 and are formed directly from hexoses. Levene had performed the reduction of cerebronic acid by concd. aq. HI and obtained a hydrocarbon instead of the expected pentacosanic acid (C_{25}). By the use of satd. HI in AcOH instead of aq. HI, the OH has now been replaced by H without reduction of the CO_2H and the product identified as lignoceric acid, $C_{24}H_{48}O_2$.

Synthesis of hydrocarbons from hydrogen and oxides of carbon. I. G. FARBENIND. A. G. Brit. 293,185, June 9, 1927. Reaction of C oxides with H or gases rich in H such as CH_4 , or steam, is catalyzed by contact masses which contain Cu, Ag or Au or their oxides or Zn together with elements of the 8th periodic group or their compds. Mn, Co, Cr, Mo, W, Ti, Sb, Bi and Zr or their compds. may be added. The products are mainly unsatd. hydrocarbons but some MeOH may also be formed. Cf. *C. A.* **23**, 1445.

Olefins. I. G. FARBENIND. A.-G. Fr. 643,413, Nov. 7, 1927. Gases rich in olefins are obtained by passing bituminous coal such as lignite in a powd. state, by means of a carrier such as superheated steam or mechanically, through a reaction zone heated to redness and cooling the products in a continuous chamber serving to sep. the coal.

Olefin oxides. I. G. FARBENIND. A.-G. Brit. 292,066, June 11, 1927. Gases such as those contg. C_2H_4 , C_3H_6 and C_4H_8 are treated with HOCl to form chlorohydrins which may then be distd. with milk of lime to produce olefin oxides and the latter may be fractionally distd. (preferably under pressure) to sep. them individually.

Ketones. SOCIÉTÉ H. GOUTHIÈRE ET CIE. Fr. 642,698, Mar. 23, 1927. Ketones are obtained by the dry distn. of crude industrial Ca lactate obtained by the lactic fermentation of sugar juices, etc., in the presence of $CaCO_3$. Crude ketones boiling from 60 to 350° are obtained which may be sepd. by fractionating. Formates, butyrates or propionates of Ca may be similarly treated to produce ketones.

Cyclic ketones. I. G. FARBENIND. A.-G. Swiss 127,692-127,703, Mar. 14, 1927. Addns. to 126,404. The method of Swiss 126,404 (*C. A.* **23**, 613) for the manuf. of α -indanone is applied in the manuf. of other cyclic ketones, as follows: A mixt. of 4- and 6-methyl-1-indanones is prepd. by the interaction of β -chloropropionic acid,

toluene and AlCl_3 (127,692). 3-Methyl-1-indanone is prep'd. from β -chlorobutyric acid, benzene and AlCl_3 (127,693). A mixt. of 4- and 6-chloro-1-indanones is prep'd. from β -chloropropionic acid, chlorobenzene and AlCl_3 (127,694). A mixt. of 4- and 6-chloro-3-methyl-1-indanones is prep'd. from β -chlorobutyric acid, chlorobenzene and AlCl_3 (127,695). The products of 127,695 are obtained when using crotonic acid instead of β -chlorobutyric acid (127,696). 3,4,6-Trimethyl-1-indanone is prep'd. from β -chlorobutyric acid, *m*-xylene and AlCl_3 (127,697). Bromobenzene is used instead of chlorobenzene in the process of 127,695, the corresponding Br compds. being obtained (127,698). A mixt. of isomeric cyclic ketones is prep'd. from β -chlorobutyric acid, *o*-dichlorobenzene and AlCl_3 (127,699). 4,6-Dichloro-3-methyl-1-indanone is prep'd. from β -chlorobutyric acid, *m*-dichlorobenzene and AlCl_3 (127,700). 5-Methyl-6,7-benzo-1-indanone is prep'd. from β -chloropropionyl chloride, α -methylnaphthalene and AlCl_3 (127,701). 3,5-Dimethyl-6,7-benzo-1-indanone is prep'd. as in 127,701 by using β -chlorobutyric acid chloride (127,702). A ketone (m. $140\text{--}142^\circ$ to which the formula

is assigned is prep'd. by condensing cinnamic acid with naphthalene in presence of H_2SO_4 , converting the naphthylphenylpropionic acid so obtained into its chloride, and effecting ring closure with AlCl_3 (127,703). Cf. Brit. 288,441 (*C. A.* 23, 606).

Cyclic ketonic compounds. HEINRICH GREUNE (to Grasselli Dyestuff Corp) U. S. 1,702,002, Feb. 12. Maleic anhydride is caused to act upon an aromatic hydrocarbon such as C_{10}H_8 or acenaphthene or a deriv. having an unsubstituted peri-position in the presence of an acid condensing agent such as AlCl_3 and PhNO_2 or other suitable solvent, at a temp. up to the b. p. of CS_2 .

Aliphatic diamines. I. G. FARBENIND. A.-G. Brit. 292,615, June 23, 1927. Aliphatic diamines contg. one secondary and one primary, secondary or tertiary amino group, are prep'd. by treating a secondary aromatic amine or nuclear substitution deriv. with an aminoalkyl halide and splitting off the aryl residue from the product. Examples are given of the production of α -diethylamino- β -methylaminoethane, α -dimethylamino- γ -methylaminobutane, α -dimethylamino- β -methyl- γ -methylaminobutane and α -dimethylamino- β -diethylaminoethylaminoethane.

Aminoalkylarylcarbinol. E. MERCK CHEMISCHE FABRIK. Ger. 469,782, Nov. 11, 1926. Amino- and N-alkylaminoalkylarylcarbinols are prep'd. by hydrogenating the corresponding ketones in the presence of a Ni catalyst. In an example, an aq. soln. of the HBr compd. of ω -N-methylaminoacetophenone is shaken with H in the presence of Ni, giving phenylethanolmethylamine, m. 77° . Similarly, phenylethanolamine, m. 40° , is prep'd. from ω -aminoacetophenone, and α -N-methylaminoethylphenylcarbinol, m. 189.5° , from α -N-methylaminopropiophenone ($\text{C}_6\text{H}_5\text{CO.CH}(\text{NH.CH}_3)\text{CH}_3$).

Mono- and polyhydric alcohols. JOHANNES MÜLLER and ULRICH HOFFMANN (to I. G. Farbenind. A.-G.). Can. 286,095, Jan. 1, 1929. A crude reaction mixt. of the condensation products of org. aliphatic compds. contg. at least one carbonyl group is hydrogenated in the presence of a catalyst comprising at least one heavy metal selected from the 1st and 8th groups of the periodic system. The hydrogenation can be carried out with or without applying pressure, and at ordinary or elevated temp., but it is preferable to work at a pressure of about 20 to 30 atm. and at a temp. of about 50° .

Azo compounds. THE PYRIDIUM CORP. Fr. 643,446, Nov. 7, 1927. Diazotized PhNH_2 is coupled with α, α -diaminopyridine in solns. of not less than 6% of HCl at a temp. higher than 12° . Two isomers, phenylazo-(β)- α, α -diaminopyridine, m. 203° , and phenylazo-(γ)- α, α -diaminopyridine, m. 135° , are formed and they may be sep'd. by fractional crystn. from boiling water. The mixt. is referred to as *pyridium* and has dyeing and therapeutic properties. If a relatively small quantity of mineral acid or an org. acid is used phenyldiazoamino-(α)- α -monoaminopyridine is formed and this by boiling with water or an aromatic amine is converted into pyridium. Analogous compds. are produced if PhNH_2 is replaced by toluidine, phenetidine, anisidine, etc. The diaminopyridine is obtained by heating pyridine with NaNH_2 and a method of purification of this compd. with trichloroacetic acid is described.

Benzyl ethyl phthalate or similar aryl alkyl esters. ROBERT H. VAN SCHAAK, JR. (to Van Schaack Bros. Chemical Works). U. S. 1,700,960, Feb. 5. Esters of this type (which are suitable for use with pyroxylin as plasticizers for lacquer films or as camphor substitutes in celluloid-like compns.) are obtained by the reaction of equimol. proportions of the polycarboxylic acid and of each of the 2 alcs. the radicals of which are desired in the finished mixed ester to be produced. Benzyl ethyl *o*-phthalate, *b*₂, 199°. In forming various mixed esters, alcs. such as MeOH, PrOH, *n*-BuOH or iso-AmOH may be used with benzyl, tolyl or phenethyl alc. or the like and with phthalic acid or anhydride or succinic, citric or phenylmalonic acid. Details and modifications of methods of making the esters are described and formulas of pyroxylin compns. contg. them are given.

Glycol esters, etc. I. G. FARBENIND. A.-G. Brit. 292,059, Jan. 31, 1927. Alkylene oxides are heated with org. carboxylic acids in the presence of an inorg. acid such as H₂SO₄ or an acid salt such as NaHSO₄ or a salt of a strong base with an org. acid other than that to be esterified. The reaction may be effected under pressure and an example is given of the production of glycol monoacetate by passing ethylene oxide into hot HOAc contg. H₂SO₄. Cf. C. A., 23, 610.

Hydrolysis of esters. EUGENE F. AYRES, JR., and ERLING H. HAABESTAD (to The B. A. S. Co.). Can. 286,076, Jan. 1, 1929. Amyl chloride is hydrolyzed by heating a substantially water-insol. fatty acid, amyl chloride and aq. NaOH in a closed vessel at 150° and thereby producing an org. ester, then heating in a closed vessel at substantially the same temp. the ester and additional quantities of amyl chloride and aq. caustic soda and sepg. amyl alc. from the resulting product.

Formation of esters and intermediate products. EUGENE F. AYRES, JR., and ERLING H. HAABESTAD (to the B. A. S. Co.). Can. 286,077, Jan. 1, 1929. (CH₂Cl)₂ is warmed in an open vessel with Na stearate at a temp. below the boiling point of the org. halide for the purpose of producing a gel. The gel is then placed in an enclosed vessel and heated to a temp. that will give the desired velocity of reaction, *e. g.*, about 150°. After the gel has been maintained at such temp. for about 1 hr. the contents of the vessel will consist of ethylene stearate together with a small quantity of soap, or a small quantity of halide which may have been present in mol. excess, and salt water.

Benzanthrone derivatives. I. G. FARBENIND. A.-G. Fr. 643,266, Nov. 2, 1927. *Bz*-1-methoxybenzanthrone is prepd. by treating with MeOH in the presence of alk. agents *Bz*-11-nitrobenzanthrone or its derivs., with or without the addn. of substances capable of destroying the HNO₂, or other benzanthrone substituted in the *Bz*-1-position by a neg. atom or group or their derivs. Examples are given of the prepn. of *Bz*-1-methoxybenzanthrone, 6-chloro(or bromo)-*Bz*-1-methoxybenzanthrone, 6-nitro-*Bz*-1-methoxybenzanthrone, 6-methyl-*Bz*-1-methoxybenzanthrone and 8-chloro-*Bz*-1-methoxybenzanthrone from the corresponding nitro, chloro or bromo compds.

Purification of diarylguanidines. COMPAGNIE DE PRODUITS CHIMIQUES ET ÉLECTRO-MÉTALLURGIQUES ALAIS, FROGES ET CAMARGUE. Fr. 643,495, Apr. 5, 1927. Diarylguanidines are extd. from the crude material contg. them by dissolving in an appropriate org. solvent, in the presence of NH₃ under pressure, restoring the soln. obtained to atm. pressure to obtain the diarylguanidine in crystal form. An example is given of the treatment of diphenylguanidine with trichloroethylene.

Naphthalene and acenaphthene derivatives. I. G. FARBENIND. A.-G. Fr. 642,907, Oct. 22, 1927. Diacyl derivs. of C₁₀H₈ and of acenaphthene are prepd. by acting on the hydrocarbons or their monoacyl derivs. or their compds. produced by the action of AlCl₃ with an aromatic or aliphatic acid chloride, if necessary with the addn. of more AlCl₃, and with or without a diluent. In examples, α -benzoynaphthalene is mixed with H₂Cl and AlCl₃ is added gradually, the temp. gradually rising. About 60% of 1,5-dibenzoynaphthalene is obtained, and about 20% of an isomer, probably the 1,8-compd. A diacetylenaphthene is prepd. from 5-acetylenaphthene by means of AcCl and AlCl₃, and a new 3,5-di(chloroacetyl)acenaphthene, *m.* 194–195°, is obtained from acenaphthene, CH₃COCl and AlCl₃. Cf. C. A., 23, 1137.

Thio ethers of the anthraquinone series. I. G. FARBENIND. A.-G. (Filip Kačer, inventor) Ger. 469,911, Feb. 3, 1927. Addn. to 460,087. Thio ethers are prepd. by reaction of a diazo compd. of the anthraquinone series with a mercaptan not of the anthraquinone series. In examples, 1-nitro-2-methylanthraquinone is converted into anthraquinone-1,2-isoxazole by the process of Ger. 360,422, and this is converted into 1-diazoanthraquinone-2-carboxylic acid by Ger. 456,859, and a soln. of 2,5-dichloro-1-mercaptopbenzene in water with NaOH is run in. Anthraquinone-1-thio-2',5'-dichlorophenyl-2-carboxylic acid is obtained. If thioglycolic acid is used, anthra-

quinone-2-carboxy-1-thioglycolic acid is obtained. Similarly diazotized 1,5-diamino-anthraquinone and *p*-thiocresol give di-*p*-tolyl ether of anthraquinone-1,5-dimercaptan.

2-Acylamino-9,10-anthrahydroquinones and derivatives. I. G. FARBENIND. A.-G. Fr. 643,243, Oct. 29, 1927. The above compds. and their derivs. contg. substituents in place of H in the 9,10 positions are prepd. by treating 2-acylaminoanthraquinones in soln. or suspension by H under pressure and in the presence of an appropriate metallic catalyst. In examples, 2-acetamidoanthraquinone in suspension in alc. or water and in the presence of Ni is treated with H under 20 atm. By methylating the product with Me_2SO_4 , the dimethyl ether of 2-acetamido-9,10-anthrahydroquinone is obtained, m. 253°. By sulfonating with ClSO_3H instead of methylating and then eliminating the acetyl group, the di-K salt of 2-aminoanthrahydroquinone-9,10-disulfonic acid ester is obtained. Similarly by a treatment of the hydroquinone with Na chloroacetate, 2-aminoanthrahydroquinone-9,10-diacetic acid is obtained.

1,8-Naphthoxyphenanthiophenes. I. G. FARBENIND. A.-G. Fr. 642,946, Oct. 24, 1927. 1,8-Naphthoxythiophenes are prepd. by heating at high temps. and under pressure 1,8-naphthothiolglycolcarboxylic acid and its derivs. substituted in the ring in an aq. soln. or suspension, preferably with the addn. of an electrolyte, such as NaCl. In examples, 1,8-naphthothiolglycolcarboxylic acid (I), m. 175–6°, is heated for some hrs. to 170–200° with water and NaCl. The 1,8-naphthoxyphenanthiophene (II) ppts. on cooling, m. 84–5°. The monobromo deriv. of I, m. 230° (by treating the acid dissolved in AcOH with Br), gives the monobromo deriv. of II, m. 130°.

Dissociation products. CHEMISCHE FABRIK AUF ACTIEN (vorm E. Schering). Fr. 642,944, Oct. 24, 1927. The prepn. of dissociation products of the ether-like condensation products of ketones with *m*- and *p*-cresols prepd. by Gaebel (*Diss*, Marburg 1903) is described; metals or metal compds. are used as catalysts. In examples, the condensation product of *m*-cresol and acetone is passed in a slow current over a layer of franconite, or SiO_2 gel charged with Ni, heated to about 300°. Dimethylcoumarin and 3-methyl-6-isopropylphenol are obtained. 4-Methyl-6-isopropylphenol and dimethylcoumaran are obtained in the same way from the condensation product of *p*-cresol and acetone.

Sodium-nitrogen compounds. DEUTSCHE DOLD-UND SILBER-SCHIEDANSTALT VORM. ROESSLER. Brit. 293,040, July 1, 1927. Na-N compds. are prepd. by the action of Na or K hydride on amino or imino compds. with or without a diluent such as toluene. Examples are given of the prepn. of the mono-Na compds. of aniline, monomethylaniline, diphenylamine, acetamide, urea, guanidine, phthalimide, succinimide, diacetamide and phenylthiourea and of the di-Na compds. of urea and guanidine. Similar reactions also may be effected with *o*- and *p*-toluidine, xylydine, α -naphthylamine, *p*-chloroaniline and benzamide; the employment as parent materials of carbazole, benzidine, α -aminopyridine, *p*-aminoacetophenone, aminotriazole and aminothiazole is also mentioned.

Molybdates. ALAN KISSOCK. Fr. 643,361 Nov. 4, 1927. Molybdenite is roasted to obtain MoO_3 which is mixed with CaO and heated to about 760° giving MoO_4Ca . The CaO is preferably added at a speed proportional to the transformation of the sulfide into MoO_3 . Cf. C. A. 22, 2444.

Alkyl ethers of 3'-nitro-4'-hydroxy- α -benzoylbenzoic acid. THE NEWPORT CO. Fr. 642,796, June 24, 1927. The above ethers are prepd. by treating 3'-nitro-4'-chloro- α -benzoylbenzoic acid with an alc. and a caustic alkali. Examples are given of the prepn. of the Me and Et ethers.

Concentrating fatty acids. HERMANN SUIDA. Austrian 111,575, July 15, 1928. The methods of prepg. concd. AcOH from dil. or crude AcOH described in Austrian 100,721 and 106,231 (see Brit. 218,271, C. A. 19, 523 and 230,447, C. A. 19, 2272) are applied to homologs of AcOH, e. g., PrCOOH .

Arylsulfonic acids derivatives. I. G. FARBENIND. A.-G. Fr. 33,204, Mar. 18, 1927. Addn. to 613,777. Arylsulfonic acids in an extremely anhyd. state are treated with chlorosulfonic acid in the presence of a higher alc. or alicyclic alc. In an example C_{10}H_8 , which has been sulfonated with ClSO_3H is treated at 60–70° with BuOH and ClSO_3H . The product is converted into its Na salt and is used as a wetting or emulsifying agent.

β -Naphtholsulfonic acids and salts. MOSES L. CROSSLEY and GEORGE S. SIMPSON (to Calco Chemical Co.). U. S. 1,701,259, Feb. 5. A soln. contg. β -naphthol-disulfonic acids, such as the mixt. produced by sulfonating β -naphthol is treated with an alk. earth metal compd. such as CaO to form salts with the acids, solids are removed by filtration, and the filtrate is treated with the hydroxide of an alkali-forming metal such as NH_4OH by which the neutral salts are converted into basic salts; after frac-

tional crystn. of the less sol. salt such as the Ca salt of "R acid," the mother liquor is treated with an NH_4 salt of an acid forming an insol. salt with the alk. earth metal such as $(\text{NH}_4)_2\text{SO}_4$, the insol. salt formed is removed by filtration and the soln. is concd. by evapn. to effect crystn. of the NH_4 salt of the β -naphtholdisulfonic acids; the sepd. mother liquor is returned to a subsequent batch mixt. to remove residual salts which it may contain.

Benzanthronecarboxylic acids. I. G. FARBENIND. A.-G. Fr. 642,826, Sept. 17, 1927. The above are obtained by oxidizing alkylbenzanthrones in the presence of an alk. agent. In examples, *Bz*-1-methylbenzanthrone is heated to about 150° in PhNO_2 with powd. KOH; on cooling and filtering the K salt of the corresponding acid is obtained. Similarly, 2-methylbenzanthrone and *Bz*-2-methylbenzanthrone are converted into the corresponding acids.

Benzanthraquinone-*peri*-dicarboxylic acids. I. G. FARBENIND. A.-G. Fr. 642,662, Oct. 21, 1927. The above, their derivs. and substitution products are obtained by treating the corresponding (*o*-carboxybenzoyl)naphthalic acids with acid condensing agents. In examples, 4-(*o*-carboxybenzoyl)naphthalic acid, m. 232° (*Ann.* 327, 101), is heated to 170 – 200° with concd. H_2SO_4 . The mass is poured into water and 1,2-benzanthraquinone-*peri*-dicarboxylic acid is pptd. Acenaphthene is condensed in CS_2 with 3,6-dichlorophthalic anhydride by means of AlCl_3 , giving acenaphthoyl-5,3',6'-dichlorophenyl-*o*-carboxylic acid. By oxidation, naphthalic anhydride-4-benzoyl-3,6-dichloro-*o*-benzoic acid is obtained. By condensing, 1,2-benzanthraquinone-5,8-dichloro-*peri*-dicarboxylic acid is obtained. Other examples are given.

Extracting acetic or other aliphatic acids from aqueous solutions. SOCIÉTÉ ANON. DES DISTILLERIES DES DEUX-SÈVRES. Brit. 290,992, May 23, 1927. In extn. with an acetic ester as described in Brit. 273,744 (*C. A.* 22, 1980), a hydrocarbon is mixed with the acetic ester; *e. g.*, a mixt. of EtOAc 75% and C_6H_6 25% may be used. Toluene, xylene and petroleum fractions similar to "petrol" also may be used.

Acetic acid. HERMANN SUIDA. AUSTRIAN 111,566, July 15, 1928. Concd. AcOH is prepd. from dil. or crude AcOH by extg. the vapors with a water-insol. solvent of high b. p., *e. g.*, cresol, in conjunction with a water-insol. solvent of low b. p. contg. $\text{C}_2\text{H}_5\text{Cl}$, CHCl_3 , CCl_4 or $\text{C}_2\text{H}_5\text{Cl}_2$. Suitable app. is described. Cf. *C. A.*

23, 4

Acetic anhydride. CONSORTIUM FÜR ELEKTROCHEMISCHE INDUSTRIE G. M. B. H. Brit. 282,114, Oct. 10, 1927. AcOH is strongly heated in the presence of small quantities of cond. catalysts, preferably feebly acid minerals which are volatile at the temp. of the reaction. In an example, P or phosphoric acid is mixed with AcOH , and passed through a horizontal tube of C elec. heated to 650° . The condensed liquid contains over 40% Ac_2O . Alkyl esters of phosphoric acid, HCl and H_3BO_3 may also be used, and the process may be combined with that of Fr. 563,452 and Ger. 417,731 in which solid catalysts are used. Cf. *C. A.* 22, 2755.

Acetic anhydride. CONSORTIUM FÜR ELEKTROCHEM. IND. GES. Swiss 127,521, May 20, 1927. AcOH vapor, heated to between 400 – 800° , is maintained at the temp. most suitable for the formation of the anhydride and treated with a catalyzer, such as molten alkali phosphate.

***o*-Amino-*o*-benzoylbenzoic acid.** THE NEWPORT CO. Fr. 642,932, Oct. 24, 1927. See Brit. 282,001 (*C. A.* 22, 3669).

***o*-Nitrochlorobenzene-*p*-sulfonic acid.** HOMER W. HILLYER (to National Aniline & Chemical Co.). U. S. 1,701,367, Feb. 5. Chlorobenzene-*p*-sulfonic acid is treated in the presence of H_2SO_4 with a nitrating agent such as HNO_3 in substantially the quantity theoretically required for the nitration, at a temp. of about 30 – 50° .

***o*-(Dimethylamino)- α -dihydroxyanthraquinonedisulfonic acids.** ROBERT E. SCHMIDT and WILLY TRAUTNER (to Grasselli Dyestuff Corp.). U. S. 1,702,022, Feb. 12. An α -diamino- α -dihydroxyanthraquinonedisulfonic acid is treated with about 5 mol proportions of CH_3O (suitably at a temp. of 95°).

Acetylene. I. G. FARBENIND. A.-G. Fr. 643,387, Nov. 5, 1927. Gases contg. C_2H_2 are enriched in this constituent by washing the gas mixt. under pressure with water or an aq. soln. In an example a gas contg. CH_4 17, H_2 80 and C_2H_2 3% is washed in a tower with water under 25 atm. pressure. The gas leaving the tower contains CH_4 17, H_2 80% and the water liberates a gas when the pressure is removed contg. 70% of C_2H_2 .

Acetone. HOLZVERKOHLLUNGS-INDUSTRIE A.-G. Fr. 642,111, Oct. 8, 1927. In the prepn. of Me_2CO from C_2H_2 and steam, substances such as metallic Fe, MnO_2 , Al_2O_3 , BaCO_3 , ZnCO_3 , are added to the usual oxide of Fe catalyst.

Diacetone alcohol. CARLETON ELLIS (to Ellis-Foster Co.). U. S. 1,701,473, Feb.

5. Acetone is treated with about 0.01–0.02% of alkali metal hydroxide in the absence of other solvent and reaction is permitted at a temp. not substantially over 30°; the alkali is then neutralized and the diacetone alc. formed is recovered by fractional distn.

Synthesis of methanol. LEONARD A. STENGEL (to the Commercial Solvents Corp.). Can. 286,288, Jan. 8, 1929. H and C oxides are passed in contact with liquid methanol under pressure, the gases are heated by thermal contact with the hot gases from the reaction, and contacted with a heated catalyst to produce methanol, the gases are cooled and the methanol formed is removed, the residual gas is combined with fresh gas, and the cycle is repeated.

Synthesis of methanol. WILLIAM J. EDMONDS (to The Commercial Solvents Corp.). Can. 286,289, Jan. 8, 1929. In the manuf. of methanol by the interaction of H and CO₂ in the presence of a catalyst and under elevated pressure and temp., the concn. of CO₂ in the gas in contact with the catalyst is maintained below 11%.

Synthesis of methanol. WILLIAM J. EDMONDS and LEONARD A. STENGEL (to Commercial Solvents Corp.). Can. 286,290, Jan. 8, 1929. Methanol is made by circulating gas contg. a ratio of H to CO₂ far greater than the theoretical proportions required for the reaction, while the reaction pressure is maintained by adding a gas contg. C oxides and H in substantially theoretical proportions.

Catalysts for methanol synthesis, etc. SYNTHETIC AMMONIA & NITRATES, LTD., and R. G. FRANKLIN. Brit. 293,056, Dec. 23, 1926. Catalysts suitable for promoting the interaction of CO and H are prepd. by heating a mixt. of basic Zn and Cr carbonates. Several examples are given. Cf. C. A. 23, 851.

Butyl alcohol and its homologs. ÉDOUARD J. S. BARBE. Fr. 642,689, Mar. 23, 1927. BuOH or its homologs is prepd. by treating a salt of the corresponding acid, e. g., Ca butyrate, with a reducing agent such as Ca formate to obtain the corresponding aldehyde and hydrogenating. An inert substance such as sand or CaCO₃ may be mixed with the reagents.

Menthol. REINISCHE KAMPFER FABRIK G.M.B.H. Fr. 33,127, Jan. 22, 1927. Addn. to 627,694. Inactive menthol, the racemate of natural menthol, is prepd. by submitting solid inactive isomenthol to an isomerization with the aid of hydrogenation catalysts such as Ni and H under pressure or not, with the addn. if necessary of thymol, inactive menthone or isomenthone, the product being sepd. by solidification or distn.

***o*-(β-Hydroxyethylamino)phenol.** I. G. FARBENIND. A.-G. Brit. 292,950, June 27, 1927. *N*-(β-hydroxyethyl) derivs. of *o*-aminophenol are made by condensing the latter with a halohydrin of glycol such as ethylenechlorohydrin in the presence of an acid-binding substance such as CaCO₃. The products are extd., after filtering, with EtOAc. The Na compd. of the *o*-[bis(β-hydroxyethyl)amino]phenol and the *o*-*o*-(β-hydroxyethylamino)phenol sulfate are readily prepd. from solns. of the bases in acetone, by use of NaOH and H₂SO₄, resp. Cf. C. A. 22, 3362; 23, 1143.

Purifying anthraquinone. HARRY F. LEWIS (to National Aniline & Chemical Co.). U. S. 1,701,186, Feb. 5. Crude anthraquinone is heated to 275–350° by circulating superheated steam in indirect contact with it and then into direct contact to effect sublimation, and the resulting vapors are cooled first at an elevated temp. to sep. anthraquinone from them and then at a lower temp. to sep. other constituents. An app. is described.

2,4-Dimethyl-6-ethoxyquinoline. HANS T. CLARKE and ERNST R. TAYLOR (to Eastman Kodak Co.). U. S. 1,701,144, Feb. 5. *p*-Phenetidine is treated with acetone in the presence of I to produce *p*-ethoxyacetoneanil and the latter is heated with HCl to convert it into 2,4-dimethyl-6-ethoxyquinoline.

2-Hydroxy-3-carboxynaphthalene salts. ERWIN SCHWENK. U. S. 1,700,546, Jan. 29. In forming alkali metal salts of 2-hydroxy-3-carboxynaphthalene, an alkali metal salt of 2-hydroxy-1-carboxynaphthalene is heated to above 200°.

Chloronaphthalene. FERDINAND JEAN. Fr. 642,681, Mar. 22, 1927. C₁₀H₇Cl, preferably prepd. by bubbling liquid Cl into melted crude C₁₀H₈, is used as a fuel either for motors or mixed with mazout for furnaces or as a lubricant.

Calcium formaldehydesulfoxylate. I. G. FARBENIND. A.-G. Fr. 643,012, Oct. 27, 1927. See Brit. 281,134 (C. A. 22, 3418).

Hydrogenation of the homologs of aniline. WILHELM LOMMEL and THEODOR GOOSER (to I. G. Farbenind. A.-G.). Can. 286,301, Jan. 8, 1929. Homologs of aniline can be hydrogenated on a technical scale and with a satisfactory yield by the action of H at elevated temp. and pressure in the presence of a catalyst contg. a substance of the group comprising Cu, metals of the Pt and Fe group of the periodic system, and suitable oxides and salts of these metals, e. g., Pt, Ni, Co, Co or Ni oxide, Co formate, Ni oxalate, etc. The time of hydrogenation varies within wide limits depending on

the nature of the catalyst, the temp., pressure and quantity of H to be combined with the starting material.

Sterols. SOCIÉTÉ ANON. POUR L'INDUSTRIE CHIMIQUE À BALE. Brit. 292,133, June 14, 1927. Sterols such as ergosterol are obtained from materials such as yeast by heating under pressure with an alk. soln. such as an alk. hydroxide or carbonate, e. g., yeast may be heated in an autoclave for several hrs. with a strong soln. of KOH. Most of the sterols sep. on the surface of the liquid and are skimmed, the skimmed material is extd. with ether and the exts. washed with water, dried with Na_2SO_4 and evapd. to effect crystn. of the sterol. Further recovery of sterol may be effected by extn. with ether of the alk. liquid.

Hydrogenation of phenol-ketone condensation products. SCHERING-KAHLBAUM A.-G. Brit. 293,001, June 29, 1927. Phenols and their hydrogenation products are obtained by catalytic hydrogenation of the etheric condensation products of alkylated phenols and ketones other than those employed in the process described in Brit. 280,956 (C. A. 22, 3499). Examples are given of the hydrogenation of dimethylcoumaran (which produces thymol and its isomers or menthol and its isomers, according to the conditions and duration of the treatment) and of the hydrogenation of the condensation product of α -naphthol and acetone (which produces a mixt. of isopropynaphthol, naphthol, isopropynaphthalene and naphthalene or their hydrogenation products).

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

Molecular weight of the hemocyanin of *Limulus polyphemus*. THE SVEDBERG AND FRANCIS F. HEYROTH. Univ. of Upsala. *J. Am. Chem. Soc.* 51, 539-50(1929).—Measurements of the mol. wt. of the hemocyanin of the horseshoe crab, *Limulus polyphemus*, have been made in dil. phosphate buffer soln. at p_H 6.63 in concns. of 0.03-0.09% of protein by the sedimentation velocity and the sedimentation equil. methods in the ultracentrifuge. Both methods indicate that at concns. of about 0.06-0.1% the protein undergoes decompn. The existence of this decompn. has been confirmed by measurements of the ultra-violet absorption, as the values of ϵ/c increase with diln. in this range of concn. The decompn. is largely, if not completely, reversible and a protein of the same mol. wt. and ϵ/c as that originally used may be pptd. from the dil. solns. by removing electrolytes by dialysis. The sedimentation velocity method indicates for the hemocyanin a probable mol. wt. of 2.04×10^6 under the conditions described.

C. J. WEST

Influence of the hydrogen ion activity upon the stability of the hemocyanin of *Helix pomatia*. THE SVEDBERG AND FRANCIS F. HEYROTH. Univ. of Upsala. *J. Am. Chem. Soc.* 51, 550-61(1929).—The variations of the sp. sedimentation velocity and the diffusion const. of the hemocyanin of *Helix pomatia* have been measured over the range of p_H from 3.8 to 8.2. Hemocyanin in 0.089% concn. in dil. acetate and phosphate buffer solns. from p_H 4.5 to 7.4 possesses a mol. wt. of 5 million. As these limits of p_H are approached, the protein mols. become hydrated and as the limits are exceeded rapidly undergo disintegration into smaller particles of undetd. magnitude. The acid disintegration is in its earliest stages reversible but the disintegration of the products first formed continues slowly and is in its later stages irreversible. The p_H ranges within which the disintegration occurs are the same as those within which the viscosity of snail serum is known to increase rapidly.

C. J. WEST

The mode of action of enzymes or enzyme systems. A. FODOR WITH LEA FRANKENTHAL AND SONJA KUK. Univ. Jerusalem. *Fermentforschung* 10, 274-301(1928).—The phenomena of varying the activity of enzymes after autolysis, adsorption and elution are explained on the basis of an exchange of "carriers" to which the hypothetical "zymoactive substance" is bound. In fresh yeast maceration the carrier is obviously a protein whose affinity for the zymoactive substance is relatively great, and the active component of the system is dislodged only with difficulty by the substrate. Adsorption on kaolin decreases the apparent activity by introducing an addnl. carrier of relatively great affinity. The filtrate from the adsorbate is still active because it contains zymoactive substance dislodged from protein but united to other carriers, the so-called concomitants (Hegleitstoffe). When the 1st adsorbate is extd. with glycine an elution is

obtained with greater activity than the adsorbate itself. An exchange of carriers has thus been effected in which a colloid has been replaced by a sol. substance giving not only a higher degree of dispersion but also a less stable union which is easily dislocated by the substrate. The enzyme complex has been changed from a "zymostable" to a "zymolabile" form with increased activity. A 2nd adsorbate obtained by treatment of this eluate with kaolin shows very little decrease in activity, because protein is no longer present, and the substrate can combine with the zymoactive substance with the same facility as when the carrier is glycine. Different types of carriers are responsible for different intensities of enzyme activity; this assumption easily explains variations in activity formerly attributed to activation and destruction of enzyme. Enzyme activity, expressed in terms of substrate cleavage, represents in reality the dislocation velocity of carrier by substrate. The increase in activity when a maceration is allowed to age is merely a matter of autolysis whereby the protein carrier is broken down and the cleavage products assume the role of carrier, the enzyme system thus changing from the zymostable to the zymolabile type. The activating effect of adding an amino acid to the macerate is an analogous phenomenon. The substrate must, however, be present in excess, since the final exchange of carriers follows the law of mass action. This explains also the fact that addn. of amino acid to autolyzed macerate is less effective than addn. to fresh macerate. The difference in behavior of the peptidase in maceration of yeast and in that of peas is due to the more rapid autolysis of the latter, thus rendering the glycine elution impracticable since amino acids from the autolysis are already functioning as carriers. A study of the influence of neutral salts on the cleavage of Witte-peptone by yeast and pea maceration shows that the lyotropic order of ions, SO_4 , AcO and Cl , becomes reversed when the reaction of the medium is changed from acid to faintly alk. In the glycine eluate, however, or after extensive autolysis the lyotropic order disappears and the Cl ion appears to exert a sp. action. The SCN ion has a sp. inhibitory action in all cases. Many phenomena of enzyme chemistry may be explained on the basis of "carrier" exchange, e. g., regeneration, stability and instability, activation of papain by HCN , the Abderhalden reaction between serum and sp. tissues, and finally the so-called zymogens or enzyme precursors.

A. W. DOX

Succinic acid as a putrefaction product in cadavers. L. VAN ITALLIE AND A. J. STERNHAUER. Univ. Leiden. *Pharm. Weekblad* 66, 14-5(1929).—Succinic acid was isolated from stomach contents, liver, brain and spleen of cadavers in incipient putrefaction, and identified by m. p. and sublimation of the free acid, and cryst. form of its Pb salt.

A. W. DOX

Sex differences of proteins in animals and plants. II. Sex differences of muscle fiber. T. TADOKORO, M. ABE AND S. WATANABE. Hokkaido Imp. Univ., Sapporo. *J. Faculty Agr. Hokkaido Imp. Univ.* 23, 1-12(1928); cf. *C. A.* 22, 1181.—Muscle freed from tendon, skin and fat was mashed in a mortar, treated with 2 vols. of physiol. NaCl soln., shaken 2 hrs. and settled 24 hrs. in an icebox. The mixt. was filtered through linen, the juice pressed out and the whole process thrice repeated. The pressed cake was washed with distd. H_2O until free from Cl , mounted into 70% EtOH for 24 hrs., then successively into 95% and abs. EtOH and finally preserved over H_2SO_4 in a desiccator for use. The acidity of the solns. which were produced by the muscle fibers of bull, cock, boar, male rabbit, male wild duck, male codfish and male hatahata (*Arctoscopus japonicus*) is always greater than that of the corresponding female muscle fibers. The existence of P in the muscle fibers of different animals was observed to be about 20% of the amt. of S%. There was, however, a tendency to find the higher S and the lower P content in the male muscle fibers of the bull, cock, boar, rabbit, wild duck, codfish and hatahata as compared with the corresponding female muscle fiber. By use of Van-Slyke's method, male muscle fiber of the different animals contained a predominance of arginine and lysine N while in the female muscle fiber there is an excess of monoamino and histidine N. The development of acidity in neutral salt solns. in the presence of male and female muscle fibers showed a corresponding tendency in the oryzenine of common and glutinous rice. The p_H value of the salt soln. produced by the male muscle fiber and by oryzenine of common rice is always less than that produced by female muscle fibers and by the oryzenine of glutinous rice. That is, the former 2 produced a greater acidity than that of the latter 2. Differences of the amino acid, S and P content were observed between male and female muscle fiber with the same tendency as in the oryzenine of common and glutinous rice. In male muscle fiber and oryzanin of common rice, there is a predominance of arginine and lysine while in the female muscle fiber and oryzanin of glutinous rice, there is an excess of monoamino acid and histidine N. Higher S content and lower P contents existed in the male muscle fibers and oryzanin of common rice. III. Sex differences of muscle proteins. *Ibid* 13-27.—Nu-

merous data show that the ash and P contents of female myosin and myogen are always greater than those of male. This explains the greater retention of H_2PO_4 in the female body. The isoelec. point of the female myosin and myogen is always more acidic, i. e., the p_H value is lower than that of the male. The rotatory power of male myosin and myogen is always greater than that of female. This fact constitutes another of the remarkable differences between the proteins of the 2 sexes. With male muscle, myosin and myogen as well as serum albumin and globulin, the quantity of HCl combined is always greater than with female. The content of free amino N of the male myosin and myogen is always superior to that of the female. The quantity of the latter is about 80–90% of the former. In male myosin and myogen there is a predominance of arginine and lysine form of N, while in the female there is an excess of monoamino and histidine forms of N. The quantities of arginine N in the female proteins are about 85% of those of the male, lysine N, 82%, while monoamino N of the male muscle proteins is about 95% of the female, and histidine N approx. 65%. As the N content of the Ac compd. of male muscle myosin and myogen as well as serum albumin and globulin surpasses that of the female and the Ac group is the reverse, a very significant difference is observed in the ratios of the Ac group to N. C. R. F.

Blood catalase. ERICH SCHILLING. *Klin. Wochschr.* 7, 2202(1928).—Blood catalase decomposes H_2O_2 so that the latter cannot injure the tissues. It is assumed, of course, that H_2O_2 is produced during the process of normal metabolism. M. H.

Observations on the function of peroxidase systems and the chemistry of the adrenal cortex. Description of a new carbohydrate derivative. ALBERT SZENT-GYORGYI. Biochem. Lab., Cambridge. *Biochem. J.* 22, 1387–409(1928); cf. *C. A.* 22, 1165.—If H_2O_2 is added to the juice of a peroxidase plant, the first quantity of the peroxide is used up for the oxidation of a "reducing factor (R. F.); this oxidation of the R. F. is catalyzed by the peroxidase. The oxidized R. F. is reduced again by other oxidizing systems. The adrenal cortex contains a reaction isomer of glucuronic acid (1) (A) can also be obtained from oranges and cabbages and forms an essential part of R. F. (A) is autoxidizable; this autoxidation is catalyzed by Cu and inhibited by cyanide. In the presence of a peroxidase and a phenol the H_2O_2 generated by other oxidizing systems can be used for the oxidation of the hexuronic acid. The oxidized hexuronic acid is reduced by the glutathione system. BENJAMIN HARROW

Note on the reduction of the disulfide group by enzyme systems. KENNETH A. C. ELLIOTT. Biochem. Lab., Cambridge. *Biochem. J.* 22, 1410–2(1928).—Neither dithiondiglycollic acid nor glutathione is reduced by succinoxidase and succinic acid. BENJAMIN HARROW

Oxidation of biosterol by ozone. ZIRO NAKAMIYA. *Bull. Inst. Phys. Chem. Research Japan* 7, 1211–43(1928); *Abstracts* 1, 116–7.— O_3 is passed through a cold soln. of biosterol in $CHCl_3$. The ozonides are sepd. into two portions by fractional solv. in petroleum ether. Both fractions give the same hydrolysis products: H_2O_2 , CO_2 , AcH , an acidic oil resembling a sesquiterpene alc., HCO_2H , $HCHO$, $AcOH$, diacetyl and $PrCHO$. Two more compds. were obtained, one having the compn.: C=67–72%, H=9–10%, while the other was acidic in character and had the compn. C=63–65%, H=8–9%. These compds. are supposed to be formed by polymerization of the primary oxidation products. ALBERT L. HENNE

William J. Gies fellowship in biological chemistry at Columbia University. FREDERICK G. GOODRIDGE, PAUL E. HOWE, WILLIAM B. DUNNING AND LEUMAN M. WAUGH. *Dental Research* 8, 679–86(1928).—An account of the history and purposes of this fellowship. JOSEPH S. HEPBURN

Recent advances in science: Biochemistry. R. KEITH CANNAN. Univ. London. *Science Progress* 23, 395–404(1929).—A review of recent work on the physiol. action of drugs, the occurrence of unsatd. hydrocarbons in animal fats, the chemistry of the tyrosinase reaction, and the acid-base relations of proteins. JOSEPH S. HEPBURN

The meaning of blood groups. B. BREITNER. *Naturwissenschaften* 16, 849–56(1928). A review dealing with the significance of blood groups for transfusion, for heredity, criminology, etc. B. J. C. VAN DER HOEVEN

The results of Naegeli's micelle theory in the study of organisms. W. J. SCHMIDT. *Naturwissenschaften* 16, 900–6(1928).—A review of the micellar structure of several biological materials. Photographs are reproduced of unpublished results on the study in polarized light of chromatin threads from isotropic nuclei of *Thalassiosira* (a radiolary); details of their structure are discussed. A few literature references are given. B. J. C. VAN DER HOEVEN

The stereochemical specificity of proteolytic enzymes. E. WALDSCHMIDT-LEITZ AND H. SCHLATTER. *Deut. Tech. Hochschule Prag. Naturwissenschaften* 16, 1026–

7(1928); cf. *C. A.* 22, 93.—Fischer's rule that only those peptides can be split by enzymes which are built up of the naturally occurring amino acid antipodes was found to be incomplete. By means of tryptic hydrolysis of a tyrosine tripeptide, *dl*-leucylglycyl-*l*-tyrosine, and of its synthetic predecessor *dl*-bromisocaproylglycyl-*l*-tyrosine, it was found that hydrolysis is complete (tyrosine sepn.) for both the *d*- and the *l*-leucine-contg. peptides. Hydrolysis by erepsin which attacks the free amino group (trypsin attaches itself to the carboxyl substrate) is, however, asymmetric. Apparently the location of enzyme attack decides about symmetric or asymmetric hydrolysis; the configuration of other groups present is immaterial. The method is valuable for the study of enzyme attack.

B. J. C. VAN DER HOEVEN

The theory of blood clotting. E. WALDSCHMIDT-LEITZ, P. STADTLER AND F. STEIGERWALDT. Deut. Tech. Hochschule, Prag. *Naturwissenschaften* 16, 1027(1928).—From the behavior of hirudin, inhibitor for blood clotting, it is probable that this process is closely related to cleavage by pepsin or trypsin kinase. The hirudin action is due to binding of thrombin in the blood, the latter being considered as a proteolytic enzyme. Several other substances cleavable by trypsin kinase have the same inhibitive action toward thrombin; examples are natural zein, histone, protamines, synthetic acylated dipeptides (benzoyldiglycine, phthalylglycine, benzoylglycyltyrosine). At the same time the corresponding dipeptides (glycylglycine, glycyltyrosine, specific substrates of erepsin) are without inhibitive effect. The conclusion is that blood clotting is a proteolytic process with thrombin as enzyme. From the fact that other proteolytic enzymes, pepsin, trypsin, erepsin and papain, are without action on the clotting process, whereas activated pancreas trypsin (trypsin kinase) accelerates it, it is suggested that thrombin is closely related to this substance, perhaps identical with trypsin kinase. For 4 cc. goat blood the clotting rate was accelerated from 10 to 4.25 min. by 0.05 trypsin units to 1.0 min. by 0.5 units.

B. J. C. VAN DER HOEVEN

Oxidation-reduction systems of biological significance. II. The reducing effect of cysteine induced by free metals. L. MICHAELIS AND E. S. GUZMAN BARRON. Johns Hopkins Univ. and Marine Biol. Lab., Woods Hole. *J. Biol. Chem.* 81, 29-40(1929), cf. *C. A.* 23, 161.—Oxygen consumption can be induced in a cysteine soln. by the free metals, Fe, Cu, Hg, Pt, Ag and Au. Pt black is very active but bright or gray Pt is much less efficient. Au acts only when deposited electrolytically on Pt and then shows only a small effect. KCN does not alter the effect of Hg but inhibits strongly the action of Pt. In general Fe and Cu are active as catalysts as salts; Hg, Pt and Au are active as the free metal; Ag is inactive in either condition.

A. P. LOTHROP

The specificity of pancreatic secretin. M. M. WEAVER. Proc. Am. Physiol. Soc., *Am. J. Physiol.* 81, 517(1927).—Purified secretin injected intravenously stimulated the pancreas to secrete but had no action on the gastric glands.

J. F. L.

The changes in p_H of feces on standing. W. THUNE ANDERSEN AND A. NORGGAARD. St. Elizabeth's Hospital, Copenhagen. *Acta med. Scand.* 69, 393-8(1928).—From the changes in the p_H of feces kept at 37° it appears that they undergo fermentation with formation of acid split products. At the same time, but more slowly, feces also undergo putrefaction with formation of alk. split products. In different cases either one or the other process may predominate. Expts. were made with equal amts of homogenized feces with the addition of 10% of either starch, glucose, olive oil, casein or milk powder. The feces to which starch, glucose or milk powder were added showed a change in p_H always toward acidity; those to which olive oil or casein was added showed very generally a change toward alk.

S. MORGULIS

The complement of amylase. VII. JONAS BONDI. Chem. Inst., Univ. Berlin. *Biochem. Z.* 203, 88-94(1928).—Amylase from pancreas manifests complement activity when used with a peptic digest of egg albumin or tryptic digest of casein. The tryptic digest of egg albumin and of casein acts as a powerful activator of starch hydrolysis, the activator not being destroyed by alkaline fermentation. Besides, the complement action depends upon the amt. of egg albumin used.

S. MORGULIS

The concentration of enzyme iron in the cell. OTTO WARBURG AND FRITZ KUBOWITZ. Kaiser Wilhelm-Inst. für Biologie, Berlin-Dahlem. *Biochem. Z.* 203, 95-8(1928).—One g. baker's yeast (dry substance) contains less than 4×10^{-7} g. respiratory enzyme Fe. Since, however, baker's yeast per g. dry substance contains about 10^{-4} g. Fe the respiratory enzyme Fe is less than 0.004 of the total Fe.

S. MORGULIS

Separation of the enzymes of barley malt. III. Amylase and maltase. HANS PRINGSHEIM AND EDUARD THILO. Univ. Berlin. *Biochem. Z.* 203, 99-102(1928).—The extn. of the malt with glycerol instead of H₂O is recommended. An 87% glycerol soln. is used and the extn. continued for 3 days. The glycerol is removed by dialysis, leaving a very active amylase soln. free from maltase. The maltase can now be extd.

from the residue freed of amylase by 87% glycerol. However, it was not found possible by this procedure to sep. cellobiase from cellulose, or mannobiose from mannanase. Maltase could also be sepd. from amylase by extn. with glycol. Both methods of extn. yield maltase-free amylase, but not amylase-free maltase.

S. MORGULIS

Relation between the structure of egg white and its ability to form threads. J. JOCHINS. Universitäts-Kinderklinik, Kiel. *Biochem. Z.* 203, 142-6(1928).—The capacity to form threads is inherent in many biol. substances. Egg white has this in a very marked degree, this capacity depending upon the presence of special structures in the substance as can be proved by the following expts.: Egg white beaten to a foam loses this capacity to form threads; fibrillar coagula are obtained when a drop of egg white is allowed to fall through boiling water or when egg white drawn out in threads is made to clot; beaten egg white never yields fibrillar coagula.

S. MORGULIS

The reciprocal effect of proteins on their solubility. G. ETISCH, W. EWIG AND H. SACHSSE. Kaiser Wilhelm-Inst., Berlin-Dahlem. *Biochem. Z.* 203, 147-58(1928).—Part of the protein pptd. with $(\text{NH}_4)_2\text{SO}_4$ by $1/3$ satn. of serum goes back in soln. on washing out with this salt. This is only partly due to a change in electrolyte concn. Principally this is due to the fact that the protein remaining in soln. influences the ppt which, however redissolves in the absence of that protein. This can be demonstrated when the washing is carried out with $1/3$ satd. $(\text{NH}_4)_2\text{SO}_4$ to which protein is added. Serum albumin was found especially effective. Furthermore, this protein effect increases with its concn. It follows, therefore, that in fractionating native serum by $1/2$ satn. with $(\text{NH}_4)_2\text{SO}_4$ one obtains 2 types of protein; one sol. in pure $1/3$ satd. $(\text{NH}_4)_2\text{SO}_4$ and another which remains undissolved in it.

S. MORGULIS

The occurrence and decomposition of pyrophosphate in cells. II. The amount of easily hydrolyzable phosphorus compounds in animal and plant cells. K. LOHMANN. Kaiser Wilhelm-Inst. für Biologie, Berlin-Dahlem. *Biochem. Z.* 203, 164-71(1928); cf. C. A. 23, 858.—Exts. prepd. from various cells deproteinized with CCl_3COOH are subjected to partial acid hydrolysis. The amt. of H_3PO_4 appearing in the first 7 min. of hydrolysis in N HCl at 100° is regarded as arising from a pyrophosphate fraction provided the amt. formed from 7 to 15 min. and at 60 min. is a small fraction of that found after 7 min. On this basis pyrophosphate was demonstrated in vertebrate and invertebrate muscles and in baker's yeast. In liver, kidney and brain it was also shown that the pyrophosphate forms a Ba salt insol. in cold water. Muscle contains 0.5-1.0 mg. P_2O_5 while yeast contains 1.6-1.8 mg. P_2O_5 per g. fresh substance. Analyses of bacteria give similar results. It is concluded that every cell possessing the ability to hydrolyze carbohydrate contains the easily hydrolyzable phosphoric acid fraction.

S. MORGULIS

Hematin formation from carbonylhemoglobin and oxyhemoglobin by dilute acids. W. LINZEL AND T. RADEFF. Landwirtschaftliche Hochschule, Berlin. *Biochem. Z.* 203, 212-7(1928).—Oxyhemoglobin and CO-hemoglobin solns. of the same mol. concn. yield, upon treatment with dil. acid, hematin solus. of different pigment content, that from O hemoglobin being 5-10% weaker. This is attributed to destruction of a part of the pigment resulting from the action of dil. acid on oxyhemoglobin. Under the influence of dil. acids corresponding amts. of ionized Fe are formed whereas this does not happen in CO-hemoglobin solns.

S. MORGULIS

The mechanism of fermentation of dihydroxyacetone. KEN IWASAKI. Kaiser Wilhelm-Inst. für Biologie, Berlin-Dahlem. *Biochem. Z.* 203, 237-66(1928).—The max. fermentation rate obtained in a phosphate soln. with 0.1% glucose is not exceeded by the addn. of $(\text{HOCH}_2)_2\text{CO}$. On the contrary, with smaller glucose concns. the addn. of $(\text{HOCH}_2)_2\text{CO}$ leads to the max. fermentation of the glucose. In yeast water or in beer wort the fermentation rate is double that in phosphate soln., but this effect is not observed in the fermentation of $(\text{HOCH}_2)_2\text{CO}$. The ratio between rate of fermentation and $(\text{HOCH}_2)_2\text{CO}$ glucose is reduced to a min. value. of about 0.7 when the yeast has been repeatedly cultured in glucose-beer wort. The $Q_{\text{CO}_2}^{\text{N}_2}$ for $(\text{HOCH}_2)_2\text{CO}$ is 90 at 20° and 150 at 28° . The oxidation quotient, which in fermentation of glucose by *S. ludwigii* is 3-4, is at first very low in the case of $(\text{HOCH}_2)_2\text{CO}$, but after repeated culturing this gradually rises and arrives at the same value as in the case of the glucose. The heat of fermentation measured colorimetrically is about 70-80 cal. more for $(\text{HOCH}_2)_2\text{CO}$ than for glucose.

S. MORGULIS

The parenteral resorption of colloids. I. MARTIN JACOBY. Krankenhaus Moabit, Berlin. *Biochem. Z.* 203, 278-9(1928).—Urease is absorbed into the blood when administered intraperitoneally. Details will be given in the next paper of this series.

S. MORGULIS

The hydrolysis of ethyl esters of lactic acid by liver esterase. P. RONA AND R. ITELSOHN-SCHRECHTER. Univ. Berlin. *Biochem. Z.* 203, 293-7(1928).—Expts. show that pig-liver esterase attacks preferably the *d*-form of ethyl esters of lactic acid when either the racemic compd. or either of the optically active modifications is used as a substrate. S. MORGULIS

Contribution to the problem of the enzymic synthesis of protein. P. RONA AND H. A. OELKERS. Univ. Berlin. *Biochem. Z.* 203, 298-307(1928).—Under the exptl conditions specified by Wasteneys and Barsook sparingly sol. products were formed from sol. protein cleavage products under the influence of pepsin. The diminution in the concn. of free NH_2 groups and of free COOH groups corroborates the assumption that this is a synthesis. When the resulting synthetic product is again subjected to peptic digestion under suitable p_{H} conditions it undergoes hydrolysis with the formation of free NH_2 and COOH groups. In tryptic digestion also sparingly sol. products are formed but these obviously undergo further cleavage. S. M

The liberation of invertin from yeast. RICHARD WILLSTÄTTER AND WOLFGANG GRASSMANN. Bayerische Akad. Wissenschaften, München. *Biochem. Z.* 203, 308-12(1928).—Digestion of killed yeast with papain liberates invertin, and this is greatly accelerated when papain is activated by HCN . S. MORGULIS

Enzymic protein hydrolysis. IV. E. MISLOWITZER. Univ. Berlin. *Biochem. Z.* 203, 323-33(1928).—In the hydrolysis of the CONH groups the freed NH_2 group belongs to the low cleavage product while the freed carboxyl group belongs to the colloidal portion. The total amt. of NH_2 groups in the colloidal fraction thus practically does not change, whereas the total amt. of carboxyl increases very markedly. Under the influence of trypsin and pepsin on casein low cleavage products of non-colloidal nature are formed through hydrolysis of CONH . S. MORGULIS

Enzymes and light. XIII. The effect of light on takadiastase in the presence of sensitizers. Y. KAMAYASHI. Städtisches Krankenhaus am Urban, Berlin. *Biochem. Z.* 203, 334-42(1928).—The injury of takadiastase in the presence of sensitizers diminishes with their concn. Eosin and Na dichloroanthracene disulfonate in a concn of 0.01% diminish the light effect only slightly, but Na anthraquinone disulfonate already has a marked effect. In the dark these substances exert no influence upon the enzymic activity. S. MORGULIS

Studies on the behavior of lignin in the natural decomposition of plants. FRANTZ FISCHER AND RUDOLF LIESKE. Kaiser Wilhelm-Inst. für Kohlenforschung, Mulheim-Ruhr. *Biochem. Z.* 203, 351-62(1928). In the natural decomposition of plants the lignin component tends to increase because the easily hydrolyzable fraction is being removed. The microscopic structure of the wood is not destroyed when cellulose undergoes cleavage, or is entirely removed. The wood structure of coal is therefore no argument against the lignin theory. S. MORGULIS

Membrane studies on the human amnion. H. RUNGE AND H. SCHMIDT. Universitäts-Frauenklinik, Kiel. *Biochem. Z.* 203, 364-9(1928).—In studying the diffusion of dyes through the amnion it was observed that generally this is greater where the dye soln. is in contact with the epithelial not the connective tissue surface. The difference was observed even when the expt. was carried out without O_2 at 37° . S. M

The mechanism of the specific ion action on proteins. The degree of activity of different myogen salts. P. RONA AND HANS H. WEBER. Univ. Berlin. *Biochem. Z.* 203, 429-51(1928).—The distribution of diffusible ions in a protein-contg. inner, and a protein-free outer soln. follows the Donnan law provided the activity of the ions inside and outside is measured. It is therefore possible to compare the activity (active concn./total concn.) of different salts of the same protein. The activity of various myogen acid salts diminishes in this order: myogen $\text{H}_2\text{PO}_4 > \text{HCl} > \text{HBr} > \text{HNO}_3 > \text{HSCN} > \text{H}_2\text{SO}_4$. The osmotic pressure diminishes very markedly and in very good agreement with the change in activity and the calcd. change according to the Donnan law. The specific pptg. effect of anions increases in the same order as the degree of activity of the myogen salts increases. Likewise the smaller the activity of the myogen salt the less is the viscosity of the myogen in soln. S. MORGULIS

Biochemical transformation of dihydroxyacetone into hexoses through fermentation and the rate of fermentation of dihydroxyacetone in connection with the caloric value of these trioses. I. CARL NEUBERG AND MARIA KOBEL. Kaiser Wilhelm-Inst. für Biochemie, Berlin-Dahlem. *Biochem. Z.* 203, 452-62(1928).—In confirmation of earlier observations that dry yeast, as well as alc.-ether or acetone preps. of *Saccharomyces ludwigii*, it is now shown that also fresh *S. ludwigii* yeast ferment dihydroxyacetone. The velocity of fermentation of dihydroxyacetone with fresh yeast is never greater than that of glucose. Since the caloric value of dihydroxyacetone is greater than

that of glucose the dihydroxyacetone cannot directly be fermented to hexose but must do so through an intermediate condensation. The direct proof of the enzymic transformation of dihydroxyacetone to glucose is obtained in the prepn. of a hexosemonophosphoric acid ester. Working with dry *S. ludwigii* with the addn. of co-enzyme in the form of beer yeast the principal product of phosphorylation is hexose-monophosphate with traces of hexose-diphosphate ester. This hexose-monophosphate is optically active, and analysis gives a C:P ratio of 6:1 so that no triose-monophosphoric acid ester is possible, because dihydroxyacetone-monophosphate could likewise be optically active. According to its properties the hexose-monophosphate ester is a mixt. of a little of Neuberg's with a great deal of Robison's ester.

S. MORGULIS

Desmolytic formation of methylglyoxal through yeast enzyme. CARL NEUBERG AND MARIA KOBEL. Kaiser Wilhelm-Inst. für Biochemie, Berlin-Dahlem. *Biochem. Z.* 203, 403-8(1928).—The special enzyme was prepd. as follows: 1 kg. Patzenhofer dry yeast was suspended in 10 l. H₂O and preserved with 200 cc. toluene. This was kept at 37° for 2 days, and centrifuged. Hexosediphosphoric ester of great purity was used as the substrate, in the form of its very sol. Mg salt. Various mixts. were made up and after incubation at 37° for 3 days the proteins were removed by means of 20% CCl₃CO₂H and from the filtrate methylglyoxal was isolated by pptn. with *p*-nitrophenylhydrazine, but still better results were obtained when pptn. was made with 2,4-dinitrophenylhydrazine, which even in the cold yields the very slightly sol. methylglyoxal 2,4-dinitrophenylosazone. By this method the presence of methylglyoxal has been proved beyond any criticism.

S. MORGULIS

The influence of p_H on the glycerophosphatase. KENTARO INOUE. Med.-chem. Inst., Chiba. *J. Biochem. (Japan)* 10, 133-45(1928).—Taka-diastrase was used as a source of the glycerophosphatase. This was freed from the so-called X-substance by the following procedure. Ten g. of taka-diastrase was dissolved in a mixt. of 200 cc. H₂O, 7.2 cc. 0.5 *M* AcOH and 42.8 cc. 0.5 *M* AcONa. To this was added 50 g. kaolin and the mixt. was shaken for 1 hr. After centrifuging the kaolin was washed twice with 250 cc. H₂O and 50 cc. of the previous acetate buffer mixt. The elution was carried out with a mixt. of 17.4 cc. 0.5 *M* AcOH + 32.6 cc. 0.5 *M* AcONa for 3 hrs. at 37°. The liquid was dialyzed 2 days against distd. H₂O in a collodion bag, and finally dild. to 500 cc. The X-substance was prepd. by boiling for an hr. on a water bath a soln. of 10 g. taka-diastrase in 500 cc. H₂O. After removing the protein coagulum by filtration the soln. was treated with 10% Pb acetate until no more ppt. was formed. The ppt. was suspended in 200 cc. H₂O and freed from Pb with H₂S. The soln. was now aerated with a stream of CO₂ and dild. to 250 cc. The raw taka-glycerophosphatase has its optimum activity at p_H 5.6. After purification with kaolin this is shifted to p_H 2.7-3.0. The activity curve at different p_H is a typical dissoen. curve, with $p_K = 4.8$. The X-substance affects only that portion of the p_H -activity curve of the purified enzyme which corresponds to the dissoen. curve of a base, and the greater the concn. of this substance the greater does the basic dissoen. const. become. The unit of X-substance is defined as the quantity necessary to shift the optimum p_H of the reaction from 3.0 to 5.0, and $\frac{1}{2}$ and $\frac{1}{4}$ units to p_H 5.0 and p_H 4.5, resp. The enzyme activities at these optima are 60, 30 and 20%, resp., of that of the purified enzyme at p_H 3.0. S. M.

Cataphoresis of glycerophosphatase. HIDEO KOBAYASHI. Med. Acad., Chiba. *J. Biochem. (Japan)* 10, 147-55(1928).—Glycerophosphatase from taka-diastrase contaminated with the X-substance migrated to the anode on the alk. side of its optimum reaction (p_H 5.56) and to the cathode on the acid side. The enzyme freed from the X-substance has its optimum reaction at p_H 3-4, but it migrates to the anode over the entire p_H range from 3.8 to 6.7. The same was found to be true when the X-substance was added to a purified enzyme sample. The difference in the migration in the elec. field is due to the greater protein content of the raw enzyme, and can also be induced in the purified enzyme through the addn. of egg albumins. S. MORGULIS

Kidney glycerophosphatase. KATSURA ASAKAWA. Med. Acad., Chiba. *J. Biochem. (Japan)* 10, 157-75(1928).—A method is described for the prepn. of the glycerophosphatase from pig kidney. The optimum reaction is at p_H 8.9-9.1, the variation depending upon the enzyme soln. The time required for a definite amt. of hydrolysis is inversely proportional to the enzyme concn. The kidney phosphatase at p_H 8.9 has practically the same activity as the phosphatase of taka-diastrase at p_H 2.8-3.0. The kidney glycerophosphatase is an ampholyte with a basic dissoen. const. $p_K = 4.8$. For the acid dissoen. const. the values for p_K are 10.8 and 9.0, resp. The activity curve for the kidney phosphatase is the mirror image of the taka-phosphatase, both curves being symmetrically arranged on either side of p_H 7.0. S. MORGULIS

"Salt hydrolysis" of starch. N. IWANOWSKY. State Univ., Saratow. *Zhurnal*

expl. Biol. Med. 10, 292-4(1928).—In working with a number of starch preps. no evidence was found of hydrolysis by salt to the stage of erythro-dextrin. Neither do hemolyzed and previously carefully washed red blood cells, nor hemoglobin solns. nor of crystallized hemin have any effect upon starch. These results thus contradict the results of Biedermann, etc.

S. MORGULIS

Enzyme action. I. Amylase from cholam (*Sorghum vulgare*). V. N. PATWARDHAN AND R. V. NORRIS. *J. Indian Inst. Sci.* A11, 121-33(1928).—To supply additional evidence of the presence of a starch-liquefying and a saccharifying enzyme in amylase, a comparative study was made of the enzymes of malted barley and malted cholam. Malting was accomplished by steeping the grains for 30-36 hrs., and germination at 20-25° in moist sand for three days. The grains were washed, dried first at 50°, then at 70° and finally at 100° and then ground. Solid enzyme was prepd. by extn. of 200 g. malt with 600 cc. of 20% EtOH for 24 hrs. and pptn. with 1500 cc. of 95% alc. The saccharifying power was detd. by Fehling's method; the liquefying power by: (a) the wt. of non-saccharin substances obtained by pptn. with 95% alc.; (b) change in viscosity at intervals of digestion. Since cholam enzyme is more active than barley enzyme with regard to liquefying power and less active as to saccharifying power, there is evidence that the ratio of saccharifying to liquefying powers is not the same in enzyme material from different sources. The starch-liquefying and saccharifying powers of cholam enzyme were affected alike by various temps. of digestion, and by the addn. of various chlorides to the digestion mixt. Of several amino acids studied for their influence upon the activity of the enzyme all except hippuric acid showed inhibitory effect upon cholam amylase, which finding is different from that obtained with barley malt amylase. Crude ext. from cholam malt and the pptd., dialyzed ext. showed optimum activity in digestion mixts. at p_H 4.66 to 4.86. **II. Nature of amylase.** D. NARAYANAMURTI AND R. V. NORRIS. *Ibid* 134-9.—Ext. of cholam malt, subjected to electrodialysis (cf. Fricke and Kaja, *C. A.* 18, 1303), showed a greater saccharifying power than the dialyzed cholam malt ext. The product of electrodialysis did not give positive protein reactions but was positive to the Molisch test. When cholam malt ext. was subjected to electroösmosis (app. similar to that used for electrodialysis) it was noted that the cathode cell liquid had a greater liquefying power and lower saccharifying power than the original liquid in the central cell. It was considered that a partial sepn. of the starch-liquefying and saccharifying enzymes had occurred. N. M. N.

Hemochromogen. M. L. ANSON AND A. E. MIRSKY. Harvard Univ. *J. Gen. Physiol.* 12, 273-88(1928).—Hemochromogen consists of a substance contg. heme (the Fe pyrrol complex, $C_{34}H_{32}N_4O_4Fe$, found in hemoglobin), combined with some N substance. It has the following equil.: Hemochromogen \rightarrow reduced heme + N substance. CN forms 2 compds. with reduced heme, one of which is cyan-hemochromogen. Reduced heme in alk. soln. has a great affinity for CN. Cyan-hemochromogen probably contains 1 CN group for each heme group. Hemochromogen prepd. from hemoglobin is a compd. of denatured globin and reduced heme. A denatured globin mol. (hypothetical mol. wt. 16,700) can convert at least 10 mols. of reduced heme into hemochromogen. This capacity to form hemochromogen is greater for globin than for edestin, which, in turn, is greater than for zein.

C. H. RICHARDSON

Syneresis and the swelling of gelatin. M. KUNITZ. Rockefeller Inst. *J. Gen. Physiol.* 12, 289-312(1928).—Solid blocks of isoelec. gelatin swell in distd. water or dil. buffer soln. of p_H 4.7 only when the gelatin content is more than 10%; blocks of lower gelatin content actually lose water. The final quantity of water lost is the same whether the blocks are immersed in a large vol. of water, or whether syneresis, i. e., the breaking up of the gel into solid lumps surrounded by liquid, has been initiated by mech. forces in the absence of an outside liquid. This indicates that syneresis is identical with the process of negative swelling of dil. gels in cold water. Gels contg. acid or alkali show greater syneresis than isoelec. gels after the acid or alkali has been removed by dialysis. Gels contg. salts show greater syneresis at the same p_H than salt-free gels after removal of the salts. The effect of these electrolytes on the syneresis of gelatin disappears at gelatin concns. above 8%. Similarity of behavior suggests that syneresis and viscosity of gelatin solns. are due to the same mechanism, namely the hydration of the micellae by osmosis, brought about by diffusible ions or by the sol. gelatin in the micellae. The greater the pressures that cause the swelling of micellae of the gelatin in the sol state, the greater the loss of water from the gels when the pressures are removed. The laws which apply to the swelling of gels of high concn. apply also to the process governing the loss of water by dil. gels. (Cf. Northrop, *C. A.* 21, 3294). Equations which represent this behavior of gelatin are given.

C. H. RICHARDSON

The effect of the hydrogen ion concentration on the rate of hydrolysis of glycyl-glycine, glycylleucine, glycylalanine, glycylasparagine, glycylaspartic acid and biuret base by erepsin. JOHN H. NORTHROP AND HENRY S. SIMMS. Rockefeller Inst. *J. Gen. Physiol.* 12, 313-28(1928).—The rate of hydrolysis of a no. of peptides by erepsin prepd. from swine intestine was detd. The p_H -activity curves obtained differed for different substrates. The curves can be predicted on the assumption that erepsin is a weak acid or base with dissocn. const. $10^{-7.6}$, and that the reaction takes place between a particular ionic species of the enzyme and of the substrate. The rate of inactivation of erepsin at various p_H values has been detd. and agrees with the above assumption that the enzyme is a weak acid or base. If the assumed mechanism is correct, the detn. of a significant value for the relative rate of hydrolysis of various peptides is an uncertain procedure. C. H. RICHARDSON

The catalytic hydrogenation of hemins and porphyrins (KUHN, SEYFFERT) 10. Structure of thymonucleic acid (LEVENE, LONDON) 10. Cerebrosides. IX. Cerebronic acid (KLENK) 10. B—METHODS AND APPARATUS

STANLEY R. BENEDICT

[Pipet for] microchemical determination of sugar and chloride in blood. K. SCHUECKER. *Wien. med. Wochschr.* 77, 1519-20(1927).—A rinsing pipet is described, the use of which avoids that of the torsion balance. B. C. A.

The use of mercurochrome and modified mercurochrome as biological stains. JESS D. HERRMANN, WESTERVELT DENNIS AND DALLAS D. DEDRICK, Okla. City Univ. *Proc. Oklahoma Acad. Sci., Univ. Oklahoma Bull., New Series* 409, *Studies Series* 29, 132-3(1928).—Glandular tissue, blood tissue and bacteria can be speedily and completely stained with mercurochrome 220 sol. Mercurochrome stains the same parts of the animal cell as does eosin. It is a superior blood stain, differentiating white and red cells. Fair nuclear differentiation can be obtained with mercurochrome as a single stain, as follows: Flood with 1% aq. soln. for 5 min., wash, dehydrate, wash in xylene, mount in balsam. Better results are produced with counter-stains (methyl-green and cotton violet) as follows: Flood with 4% aq. soln. of methyl green for 7 mins., flood with H_2O , flood with 1% mercurochrome for 3 mins., dehydrate, immerse in xylene, mount in balsam. RUSSELL C. ERB

Progress and experience in the examination and diagnosis of urine. F. SPAETH. *Arch. Pharm.* 266, 703-23(1928).—A discussion of chem. and phys. procedures for the prompt diagnosis of urine. W. O. E.

The isolation of secretin—its chemical and physiological properties. JOHN MEL-LANBY. St. Thomas's Hosp., London. *J. Physiol.* 66, 1-18(1928).—250 g. intestinal mucosa from pigs duodena were ground with sand and extd. with 1000 cc. abs. EtOH for 30 mins. at room temp. and filtered. The filtrate was concd. *in vacuo* to opalescence and filtering; then H_2O was added to the original vol. Fats and soaps were pptd. at 20° by adding 1 cc. *N* $CaCl_2$ to each 100 cc. of the fluid. The ppt. was collected on a coarse paper and discarded. The clear filtrate was cooled on ice and 2 cc. of 10% com. Na taurocholate soln. added to each 100 cc. fluid. After mixing, AcOH was added to 0.2% concn. The mixt. was left 2 hrs. in the ice box and the ppt. was then dissolved in a small vol. of abs. EtOH. Any undissolved matter was sepd. by centrifugalization and discarded. The alc. soln. of secretin and bile acid was added to 5 vols. of acetone. The ppt. was obtained by centrifugalization and washed twice with acetone. It was then dissolved in a small vol. of H_2O and the secretin pptd. by adding AcOH to 0.1% concn. The ppt. was obtained by centrifugalization and dried in the centrifuge tube by means of acetone and ether. Secretin is a polypeptide, contg. P, tyrosine and probably histidine. It is slightly sol. in H_2O , and in dil. alkali; insol. in EtOH, $MeCO$ and Et_2O . It is rapidly destroyed in acid or alkali at 100° and by pepsin, trypsin and autolytic enzymes at 38°. It is adsorbed by bile acids, charcoal, alumina and hardened filter paper. It is most effective when given intravenously. It is not absorbed from the digestive tract even in the presence of bile. It acts on the external

secretions of the pancreas and liver, increases the tone of smooth muscle and has no effect on arterial blood pressure, although it produces local vasodilatation in the pancreas. It has no action on the salivary glands, the gastric mucosa or the glands of the small intestine and is without action on voluntary muscle. J. F. LYMAN

The determination of sugar in small quantities of liquids by the method of Gabriel Bertrand. G. HUMBERT. *J. physiol. path. gen.* 26, 377-83(1928); cf. *C. A.* 1, 1630.—The Bertrand method is modified for use with 2 cc. of blood or other body fluid. The Na-tungstate filtrate is boiled with the usual amts. of CuSO_4 soln. and alk. tartrate soln., plus 1 cc. of a standard glucose soln. to prevent spontaneous reduction of the Cu. The glucose soln. consists of 10 g. pure anhyd. glucose dissolved in 1 l. of a soln. of 2.5% benzoic acid. For titrating the Fe reduced by the Cu_2O a permanganate soln. is used in which 1 cc. is equiv. to 2 mg. Cu. L. A. MAYNARD

The determination of urea by urease. G. HUMBERT. *J. physiol. path. gen.* 26, 392-7(1928).—This is a simple, clinical method for use with urine, blood and other body fluids. The urea of the phosphotungstic acid filtrate is hydrolyzed for 1 hr. with 3 to 4 g. of *Canavalia* urease with the addn. of 5 cc. of a soln. contg. 2 g. H_3PO_4 and 14 g. $\text{Na}_2\text{P}_2\text{O}_7$ in 100 cc. H_2O and the NH_3 distd. into 0.1 N H_2SO_4 . During distn. air freed from NH_3 by passing through H_2SO_4 is drawn through the app. by suction. The excess standard H_2SO_4 is treated with 5 cc. of 10% KI and 2.5 cc. of 5% neutral KIO_3 and the liberated I titrated with 0.1 N $\text{Na}_2\text{S}_2\text{O}_3$. L. A. MAYNARD

A practical wash bottle for measurements by the gas chain and for other purposes. H. SCHREUS. Hautklinik, Med. Akad., Düsseldorf. *Biochem. Z.* 200, 339(1928). See figure in the text. S. MORGULIS

Preservation of urine. GIACOMO TELLERA. *Boll. chim. farm.* 67, 577-80(1928) --- T. discusses the different means by which urine may be preserved. According to his experience, urine remains unaltered for several days by adding 0.15% BzOH (I) or 0.3% BzONa (II). In case that the urine is only slightly acid or neutral, 0.25% of I or 0.5% of II is required. II is to be preferred because it will not interfere with the acidity detns. Since the presence of II might disturb the tests for glucose, especially when employing Fehling's reagent, it is safer to eliminate it from the urine by Courtonne's reagent (30 g. $(\text{AcO})_2\text{Pb}$ in 100 cc. H_2O contg. a small quantity of AcOH). *p*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{Me}$, which does not interfere with Fehling's reagent, also proved to be a good preservative in a concn. of 0.15%. C—BACTERIOLOGY

CHARLES B. MORREY

A milk-fermenting yeast. C. S. R. AYYAR. Agr. Research Inst. Pusa, *Bull.* 183, 5 pp.(1928).—By repeated plating in purple lactose agar, a yeast capable of producing alcoholic fermentation of milk was isolated from sterilized milk which had curdled with an acid flavor. In general the yeast cells are oval or elliptical, being 5 to 7.5 μ long and 4.8 μ broad after 24 hrs. culture in purple lactose agar. Some are round, 4.8 μ in diameter, while elongated cells, 16 μ in length, are found in old cultures. The yeast is non-spore-forming; young cultures are Gram positive; it does not liquefy gelatin; it grows well on maize ext. agar and purple lactose, but scantily on peptone bouillon and potato; it stains readily with the ordinary aniline stains. The optimum temp. for growth is about 30° and the best growth is obtained with a plentiful supply of O; however the yeast is a facultative anaerobe. The thermal death point is 66°. The yeast is similar in many respects to *Torula lactis* but differs from it in the size of the cells and the thermal death point. Gas was produced in milk and in dextrose, levulose, galactose, saccharose and lactose bouillons but no growth was obtained in maltose bouillon. No gas was produced in mannitol, raffinose, arabinose and glycerol bouillons, although growth took place. There was slight growth in salicin bouillon. The yeast was without action on pasteurized cream when inoculated samples were incubated at 30° for 4 days. An 80% conversion of the lactose to alc. was obtained by incubating inoculated samples of steamed sepd. milk at 30° for 6 days. Similar results were obtained with sterilized whey which had been neutralized with NaOH prior to incubation. Very little fermentation took place in acid whey. The yeast possesses possibilities for the economical production of alc. from whey. K. D. JACOB

Twort-d'Herelle phenomenon. B. N. ASTAPOV AND V. K. VARISHCHEV. *Trans. Sci. Chem.-Pharm. Inst. (Moscow)* No. 14, 13-21(1926).—The authors conducted a series of expts. injecting colon bacilli into guinea pigs, and checked the work of Bordet and Cinca. No corroboration could be obtained. The expts. of Callou were also checked, staphylococci from boils and other infections from humans being used. They found no lytic effects. The conclusion is that the views of d'Herelle seem to stand.

J. S. JOFFE

Effect of distilled water upon the tendency to colony formation upon Petri plates. C. S. MUDGE AND B. M. LAWLER. Univ. of California. *J. Dairy Sci.* 11, 436-45 (1928).—In plating out milk there is a significant rise in count if the milk-water diln. be allowed to stand, even in ice water. This is due to dispersion of the clumps, possibly by change of p_H on diln. It is prevented by dilg. in a phosphate or peptone buffer of p_H 6.6.

F. L. SEYMOUR-JONES

The decomposition of fats by bacteria. F. E. HAAG. *Arch. Hyg.* 100, 271-308 (1928).—The ease with which the unsatd. fatty acids are decompd. by bacteria and by fungi depends upon the no. of double bonds in the fatty acid mol. attacked and not upon the phys. properties of the latter. The biol. properties of the acids are also influenced by the arrangement of their constituent atoms, since elaidic and brassidic acids are not as susceptible to decompn. by fungi as are their stereoisomers, oleic and erucic acids. The decompn. of oleic acid through bacterial action proceeds more smoothly than when it occurs as the result of spontaneous oxidation and fewer intermediate products are formed. The utilization of palmitic and of stearic acids by the higher fungi and by *B. pyocyaneus* is probably preceded by a spontaneous dehydrogenation of the acids, which renders them more available. The production of rancidity in fats is not alone the result of the activity of microorganisms.

E. R. MAIN

Bacterial oxidation of crude oils. V. O. TAUSON. State Polytechnic Museum, Moscow. *Neftyanoe Khozyaistvo* 14, 220-30(1928).—*Penicillium* develops on paraffins m. 45-56°, utilizing 80% of the hydrocarbon. *B. fluorescens liquefaciens*, *B. pyocyaneus*, *B. stutzeri* and others utilize paraffins as well as kerosene. Microorganisms obtained from the Baku region (bacteria as well as the mold *Aspergillus flavus*) can utilize hard as well as soft paraffins (m. 78° and 45°) or white vaseline. Conditions necessary for the oxidation of the paraffins are as follows: (1) Presence of water with the mineral salts dissolved in it, the presence of either nitrate or NH_4 salts being a matter of indifference, except that in the latter case $CaCO_3$ must be available to neutralize the acid set free on the escape of NH_3 . (2) Free access of O_2 is essential. (3) The reaction of the soln. should be as nearly as possible neutral. The amt. of paraffin oxidized under favorable conditions is really considerable. The microorganisms utilizing paraffin can also oxidize fats and fatty acids, and *Aspergillus flavus* can also utilize some plant and animal waxes and higher alcs. The oxidation of paraffin to higher fatty acids is doubted because there is no evidence of increasing acidity in the cultures. It is believed that the paraffins are oxidized to CO_2 and H_2O . The question of the oxidation of naphthenes is still open. Members of the olefin group are apparently easily oxidized, and the oxidation of terpenes likewise seems very probable. The oxidation of aromatic compds. by microorganisms is much better known. *B. benzoli* utilizes about 8 g. C_6H_6 in about 34-42 days in the presence of nitrates. This organism oxidizes also toluene and xylene. The bacterial oxidation of the aromatic hydrocarbons with low b. p. differs from that of the oxidation of hydrocarbon of high m. p. in that the former must be in aq. soln. and that partial pressure of the vapor must be in equil. with that of its aq. soln. These conditions are generally satisfied in nature where crude oil undergoes bacterial oxidation. Several types of bacteria were isolated from specially prep'd. cultures contg. the aromatic hydrocarbons in soln. The chemistry of the bacterial oxidation of C_6H_6 and its homologs is not clearly understood. The oxidation of diphenols by bacteria is very rapid, but the organisms are different from all those responsible for the oxidation of other hydrocarbons. Three types of organisms (*B. naphthalenicus liquefaciens*, *B. naphthalenicus* and *B. naphthalenicus nonliquefaciens*) utilize naphthalene as a source of C, and in some expts. nearly 50% was oxidized in the course of 6 weeks, this being even a more rapid rate than in the oxidation of paraffins. *o*-Phthalic acid is obviously not an intermediate product in the bacterial oxidation of naphthalene, nor do the expts. indicate that pyrocatechol is a possible intermediate step. Phenanthrene is easily oxidized by several varieties of *B. phenanthrenicus* but anthracene is attacked slowly. All these findings support the contention that crude oil under the conditions in nature undergoes progressive oxidative destruction. The fact that the soil in the oil-bearing regions is rich in a great variety of microorganisms utilizing hydrocarbons and displaying considerable specificity, and the fact that the natural conditions so very nearly

approach the optimum for their activity, lead to the conclusion that they play a very large role in those alterations of the crude oil which take place in it before it comes out from under the ground.

S. MORGULIS

The Gram stain. The chemical structure of the fatty acids of yeast, and a study of yeast cells made artificially Gram positive. JOSEF SCHUMACHER. *Centr. Bakt. Parasitenk.*, 1 Abt., 109, 181-92(1928).—By HCl-ether hydrolysis of yeast cells, previously freed from free lipoids, there is produced a karyonin-fatty acid mixt. which is a brownish yellow ppt. The fatty acids in this residue can be sepd. from the karyonic acid, because the latter is difficultly sol. in alc. The Gram positive fatty acid of yeast is N-free, unsatd. and contains phosphoric acid. It combines with protein to form the Gram positive lipo-protein of yeast. Yeasts and Gram positive bacteria can be made artificially Gram negative by hydrolysis with HCl-alc. These Gram negative cells again become Gram positive if allowed to remain in contact for several hours with an alc. soln. of lipoids thus split off. Free lecithin or other lipoids, even if extd. from yeast by simple solvents, will not act thus.

JOHN T. MYERS

Studies on the "bios question." G. I. WALLACE AND F. W. TANNER. Univ. of Ill. *Centr. Bakt. Parasitenk.*, 2 Abt., 76, 1-17(1928).—Studies on the "bios" question must be made with cultures of abs. purity. Ordinary pressed yeast must be plated to free it from gross bacterial contamination. This may explain much contradictory data in the literature. One cannot predict what the effect of another microorganism will be on the growth of a culture of yeast in a mineral salt-sugar mixt. Nineteen hundred single cell inoculations of 4 yeasts were made in 6 different synthetic media. Single cells of yeast will grow in pure mineral salt-sugar solns. There were great variations in the growth of the different cells, each being an individual unit. Different species or varieties of yeast act differently in the same medium and the same species acts differently in different salt-sugar mixts. Data obtained by using a large inoculum cannot be compared with data from a small inoculum. A vitamin accessory substance, or the supposedly sp. substance "Bios," does not seem necessary for yeast growth, in the case of the 4 yeasts studied, but they represent different classes and the finding may apply to all yeasts. Yeasts grow better if organic material is added to the salt-sugar mixts., but it is probable that many org. substances may serve as a stimulant. There is a good bibliography.

JOHN T. MYERS

The influence of iodine upon the growth and metabolism of yeasts. J. E. GREAVES, C. E. ZOBELL AND J. DUDLEY GREAVES. Utah Agr. College Expt. Sta., Logan. *J. Bact.* 16, 409-30(1928).—Growth and metabolism of yeasts are extremely slow in a mineral salt-sugar soln. such as Mayer's cultural fluids when it is prepd. from purified chemicals. Heavy seeding or the presence of impurities, such as may occur in com. beet sugar, bacterial and mold growth (especially the latter), accelerates yeast multiplication. Small quantities of I, 1 part per million, either as elementary I or the salts of Na, K or Ca accelerate yeast growth. If this is due to impurities rather than to the I, they would have to be almost infinitesimal in amt. I seems to be essential to yeast growth. It is possible that yeast can build I into org. compds. which may be valuable to higher animals and may be a valuable means of administering I to man. It would be less irritating than inorg. I, and the dosage could be nicely controlled. Org. or inorg. compds. of I may possibly be the cause of the phenomena attributed to Wilder's bios; although bios seems to have a greater accelerating power.

JOHN T. MYERS

Factors which influence the heat destruction of tubercle bacilli in milk. K. KATRANJIEFF. *Compt. rend. soc. biol.* 99, 1478-81(1928).—Guinea pigs inoculated with 1 cc. of non-heated tuberculous milk showed tuberculous lesions in 2 or 3 months. Animals inoculated with whole or skimmed milk which had been heated to 58° for 30 mins. and having a pH of 6.3 or 6.7 showed similar lesions. Animals inoculated with skimmed milk which had been heated to 58° for 30 mins. and having a pH of 6.0, and animals inoculated with whole or skimmed milk heated to 63° and having a pH of 6.0, 6.3 or 6.7 showed no tuberculous lesions within 3 months.

Calcium ion and root growth. W. MEWIUS. *Jahrb. wiss. Botan.* 66, 183(1927).
 O. LOEW. *Forts. Landw.* 1927, 2.—The classification of plants according to the effect of Ca salts on their growth is considered in view of the results of treatment with KCl and MgSO₄ as influenced by reaction and temp. The theory of the "lime factor" (Loew) is not fully supported by the author's results, which accord more closely with the Hanstein-Cranner conception of the effect of the Ca ion in reducing the permeability of the protoplasm. Other injurious effects follow this action. The stability of protoplasmic permeability is specific to plants. Loew observes that the death of cells brought about by treatment with salts which ppt. Ca can be watched microscopically, and asserts that the cell nucleus contains important Ca compds., and when these are decomposed by pptn. the cell must die. This view does not conflict with the fact that K₂CO₃ and Na₃PO₄ are less active in destroying protoplasm than are K₂C₂O₄, NaF and Na₄P₂O₇.

The chemical composition of mangolds grown in mid Wales. T. W. FAGAN AND J. E. WATKIN. Univ. Coll., Aberystwyth. *Welsh J. Agr.* 4, 102-13(1928).—In expts. with 5 varieties of mangolds, the Yellow Globe variety in general had the lowest content of dry matter but the dry matter of this variety contained the highest percentages of sugar, protein and SiO₂-free ash. With the exception of the Red Intermediate variety, mangolds sown early in the season were distinctly lower in dry matter than those sown later, and the dry matter of the early sown mangolds was appreciably lower in sugar and protein content. The chief effect resulting from the application of nitrogenous fertilizers was to increase the percentage of protein in the dry matter. The application of NH₄Cl or heavy dressings of (NH₄)₂SO₄ reduced the percentage of dry matter and sugar. Applications of K₂O appeared to narrow the ratio of true to crude protein, indicating that it caused the roots to mature earlier than those receiving no K₂O. Storage of the mangolds in clamps until spring resulted in a decrease in the dry matter and sugar content, but the percentage of true protein in the dry matter was greatly increased. The dry matter was also richer in SiO₂-free ash, and, with the exception of SiO₂ and Cl, in the majority of the mineral constituents detd. Allowing the mangolds to run to seed resulted in a reduction in the dry matter and sugar content, the reduction in the latter amounting to an av. of about 29% of the sugar originally present. Mangold leaves had the following compn.—crude protein 21.64, SiO₂-free ash 19.00, CaO 2.19, P₂O₅ 0.98, and K₂O 5.61%.

Seasonal variations in the physical and chemical properties of the leaves of the pitch pine, with especial reference to cold resistance. BERNARD S. MEYER. Ohio State Univ. *Am. J. Botany* 15, 449-72(1928).—A study was made of the seasonal variations in the sugar and the water content, and the vol. of water expressed as sap under pressure after various treatments for the leaves of the pitch pine. The total water content of the mature leaves of the pitch pine does not exhibit any marked variations. It is highest in the recently developed leaves during the first summer of their existence. The water content decreases very slowly during the autumn and winter months until April or May and rises slightly during the following summer months. The lowest leaf water contents occur in the late spring at a season when the leaves are seldom subjected to freezing temps. During the summer months the leaves of the pitch pine are readily killed by freezing in an ice-salt bath and the sap is easily expressed. In the winter the yield of sap from leaves treated in the same way is much smaller, showing that the leaf cells are not killed by the freezing process. The increased water-retaining capacity of the cells in the winter is believed to be due to an accumulation of colloidal gels, which increase the proportion of bound water in them during the late autumn months. The colloidal content of the leaf cells is also believed to decrease in the late spring, accounting for the decrease in the water-retaining capacity of the tissues which occurs at that season. Unfrozen samples of the leaves of the pitch pine show a greater resistance to dehydration under pressure in the winter than in the summer. This is regarded as contributory evidence for the view that there is an accumulation of colloidal gels in the leaf cells during the winter months, since it is to be expected that tissues in this condition would show a greater resistance to dehydration under pressure than tissues in which only a relatively small amount of the water was bound by imbibitional forces. It is believed that the seasonal variation in the relative proportions of bound and unbound water is the most important factor in the cellular physiology of the leaves of this species in relation to cold resistance. That this seasonal variation in the proportion of bound water is due primarily to the seasonal changes in the amt. and condition of the cell colloids appears to be well established. The low winter values for the osmotic pressure lead to the conclusion that this is only a minor factor in the cold resistance of pitch pine leaves. Since, however, it seems certain that the proportion of H₂O available for soln. is reduced in the winter, it is conceivable that the winter osmotic pressure of the cell sap may be much higher than detns. of the osmotic value of the expressed leaf saps seem to indicate, and, therefore, of greater significance than the available exptl. data seem to show. The sugar content of the leaves of the pitch pine increases during the autumn months, is relatively high during the winter, decreases during the spring, and is relatively low during the summer. The increase in sol. carbohydrates during the winter months is undoubtedly the important factor in causing the increase in the winter osmotic values of the saps expressed from these leaves. This accumulation of sugars may also be of importance in the cold resistance of pitch pine leaves through the protective action which sugars exert against pptn of proteins.

J. J. SKINNER

Composition of fungus hyphae. I. The fusaria. R. C. THOMAS. Ohio Agr. Expt. Sta. *Am. J. Botany* 15, 537-47(1928).—Analyses of the cell walls of 12 different species of *Fusarium* were made and the same general structural plan was found to hold for the group. The outer covering of the hyphae was found to be a protein-pectic-compd., a cellulose-fatty-acid complex with a basic skeleton of chitin. The relative quantity of cellulose was very small and the complex with which it was associated had to be broken up before it could be demonstrated. The protein- and pectic-compound part of the complex could be removed by the use of an ammoniacal soln. of $\text{Cu}(\text{OH})_2$ and of 0.5% ammonium oxalate. The fatty acid extd. with hot alc. KOH was found to have an I value of 88.9 and n_{D}^{20} 1.4765. In young cultures the amt. of fatty acid was found to be as high as 8.3% of the original dry wt. of the mycelium while the free uncombined oils and fats constituted 6.8%. It is suggested that the high oil and fatty-acid content in part accounts for the resistance of *Fusarium* hyphae toward the action of strong acids, as well as other reagents. The striking analogy between the structure of the apical meristem of broad bean and of the *Fusarium* hyphae is pointed out. J. J. S.

Relation of cotton root rot and Fusarium wilt to the acidity and alkalinity of the soil. J. J. TAUBENHAUS, W. N. EZEKILL AND D. G. KILLOUGH. Texas Agr. Expt. Sta., *Bull.* 389, 19 pp.(1928).—Root rot of cotton, caused by the fungus, *Phymatotrichum omnivorum*, is the most destructive disease of cotton in Texas. It is especially serious in the "black lands," where the heavy soils usually contain much Ca. The present study was planned to det. whether the distribution of the disease in Texas is actually correlated with differences in the acidity or alk. of the soil. Lab. studies of the growth of the fungus on culture media showed that it grew best at about the neutral point, pH 7.0, and that it would not grow so well in more acid or in more alk. media. Cotton fields in 16 counties of Texas were examd and the acidity or alk. of the soil was studied in relation to the presence of cotton root rot and also of *Fusarium* wilt. Root rot was found in acid soils (pH 5.5-6.4) as well as in neutral (pH 6.5-7.4) and alk. soils (pH 7.5-9.0). However, in the alk. and neutral soils the percentage of fields in which the disease was present was twice that in the acid soils, and root rot was also much more destructive in these fields than when it was found in acid soils. *Fusarium* wilt, on the contrary, was much more common in the acid soils. It is probable that the differences in the distribution of these 2 important cotton diseases can be explained as due in part to differences in soil acidity. J. J. SKINNER

Oenanthe sarmentosa. F. J. GOODRICH AND E. V. LYNN. Univ. of Wash. *J. Am. Pharm. Assoc.* 17, 1096-104(1928).—Several species of *Oenanthe* are known. Some are toxic; the poisonous properties of others are undetd. *Oenanthe sarmentosa* grows in swamps, or on the banks of streams or sometimes immersed in water. Leaves and stems, leaves from submerged plants and rhizomes and roots were collected at intervals throughout the season (1926 and 1927). On drying in the air the various parts lost from 71.5 to 79.4%; at 105° the losses ranged from 77.3 to 88.4%. The stems and leaves lost to petr. ether 1.56 to 1.80%; to Et_2O 3.99-3.96%; to CHCl_3 0.84-0.80%; to EtOH 19.8-23.7%. The rhizomes and roots lost to petr. ether 2.84-2.96%; to Et_2O 2.74-26.2%; to CHCl_3 0.61-0.62%; to EtOH 29.-29.4%. Alkaloids were absent, glucosides, pectins, gums or dextrans, sucrose, resins and starch were found in the rhizomes. All parts of the plant contain a volatile oil which contains S. α -Phelandrene is a component of the fruit oil while furfural is contained in the oil from the leaf and rhizome. Pharmacologic tests indicated that the plant is non-poisonous. L. E. WARREN

Agglutinins in plants. M. EISLER AND L. PORTHEIM. *Ans. Akad. Wiss. Wien* 63, 35-6(1926).—Agglutinins are not found in leaves, stems, roots, anther sacs, pollen, or seed anlage" of *Phaseolus multiflorus*. In this plant, and in *Ricinus communis* and *Datura stramonium*, it is found in the seed at a particular stage of development and of deposition of reserve protein. It is contained largely in the albumin fraction. It is probably not a protein, but a "building stone" of a protein. J. J. WILLAMAN

New color reactions of biosterol. SADAYUKI HAMANO. *J. Agr. Chem. Soc. Japan* 4, No. 1; *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 392-7(1928); *Abstracts* 1, No. 4, 36-7(1928).—Biosterol was prepd. by Takahashi's method; the unsapon. matter of cod-liver oil was purified by removal of the ppts. produced in its acetone soln. by cooling to -65° , and of traces of cholesterol by means of digitonin. Biosterol thus prepd. gave all the known color reactions attributed to vitamin A; *i. e.*, it presented, like cod-liver oil, a blue color by addn. of a strongly dehydrating agent such as concd. H_2SO_4 , H_3PO_4 , P_2O_5 , acid clay or $AlCl_3$, $ZnCl_2$, $MgCl_2$, $TiCl_2$, $AsCl_3$, or $SbCl_3$. The following new color reactions have been found with polyphenols, aromatic and heterocyclic amines: (1) Phloroglucinol: to an alc. soln. of biosterol, a small quantity of phloroglucinol and a few drops of concd. HCl are added. A green color appears, which turns blue, then remains unchanged for about 10 mins., then becomes Prussian blue and finally rose-pink. In the case of cod-liver oil, a pink color which first appeared in place of the green one turned blue very slowly. In the following tests a similar exptl. procedure is to be followed, except that phloroglucinol is replaced by the reagent indicated. (2) Orcinol: lemon-yellow. (3) Pyrogallol or resorcinol green for a few min. (4) Naphthol resorcinol: deep green persisting for several days. (5) Aniline, xyldine, benzidine, naphthylamine or phenylhydrazine: crimson red. In this case further addn. of glacial AcOH was needed. (6) Indole: dark green gradually turning to brown. (7) α -Methyl-indole: blue as in (1). (8) Skatole: yellowish brown. (9) Pyrrole: green turning to dark brown immediately. (10) Quinaldine: yellowish brown. The color reaction with phloroglucinol or naphthylamine is effective with $1/800,000$ of biosterol. Many aliphatic and aromatic aldehydes when condensing with one of the above reagents produce special colors or ppts. Furfural shows a close resemblance to biosterol in its color reactions, but biosterol reduces Fehling soln., ammoniacal silver oxide and phosphomolybdic acid. From these facts it is not unreasonable to infer that biosterol may contain a carbonyl group in its mol. The color reactions mentioned above are not given by cholesterol.

The relation of food to the composition of milk. R. O. DAVIES AND A. L. PROVAN. Univ. Coll., Aberystwyth. *Welsh J. Agr.* 4, 114-21(1928).—The effect of summer grazing on the chem. compn. of milk from 14 cows was studied. The milk was sampled immediately before grazing and a fortnight after the cows had been out on grass. The results indicate that after a fortnight's grazing there is generally an increase in the total protein, casein, total P, inorg. P and Ca concn. of the milk. These changes in the compn. of milk were found to depend on the system of winter feeding to which the cows were subjected before being let out on grass. Animals fed on a "low protein" winter ration gave milk contg. higher concns. of total and inorg. P and casein after grazing than was found in milk from animals fed on "control" winter rations. The results are of considerable importance in that they may throw light on the relative efficiency of different winter rations advocated for dairy cows. The rise in concn. of the constituents of the milk occurred simultaneously with an increased flow of milk, which may be due either to an improvement in the health of the animals as a result of being left out overnight; to the much higher nutritive value of the summer grass in comparison with the winter rations; or to a specific effect of some constituents of the grass on the milk gland.

K. D. JACOB

Effects of irradiated ergosterol in animal experiments. W. FRANNENSTIEL. *Munch. med. Wochschr.* 75, 1113-4(1928).—Large daily doses of irradiated ergosterol produced acute and fatal symptoms in animals. Later expts. with 2 drops of vigantol (1% irradiated ergosterol in olive oil) daily produced the characteristic symptoms of hypervitaminosis in healthy adult rabbits. The symptoms disappeared when the vigantol was removed from the diet and reappeared upon its readministration. Control animals gained weight. No permanent injury was noted in the animals not succumb.

Hydrogen sulfide in blood in uremia; hydrogen-sulfide-decomposing power of blood and other body fluids. E. BECHER. *Münch. med. Wochschr.* 74, 1950-1(1927).—In severe renal insufficiency and true uremia H_2S could not be detected in the blood; that obtained on acidification and distn. probably arose from thiocyno compds. All body fluids can oxidize H_2S to thiosulfuric acid. The disappearance of H_2S added to blood does not depend on the formation of sulfohemoglobin.

B. C. A.

The resorption of bile acids from the normal and from the inflamed gall bladder.

F. ROSENTHAL AND H. LICHT. *Klin. Wochschr.* 7, 1952-4(1928).—Bile acids are resorbed by the mucous membrane of the normal gall bladder. The resorption rate is enormously increased when the gall bladder is inflamed by the intravenous injection of Dakin's soln. or of turpentine. MILTON HANKE

The specific dynamic action of liver. ROBERT E. MARK. *Klin. Wochschr.* 7, 2012(1928).—It is well known that the ingestion of meat (muscle) temporarily increases O consumption in normal individuals. This is not the case with liver. Ingestion of liver may lead to a slight increase in O consumption; but it may also lead to a decreased consumption. Kidney tissue is less effective than meat. In hepatopathics, ingestion of liver leads to an increased metabolism that is not far short of that produced by muscle. MILTON HANKE

Paroxysmal hemoglobinuria. ÖDÖN FISCHER. *Klin. Wochschr.* 7, 2061-2(1928).—A mixt. of swine serum plus lipid (alc. ext.) from guinea pig corpuscles injected into rabbit's engenders hemolysins against guinea pig corpuscles. The changes produced in the rabbit's serum may be identical with the changes produced in human serum in cases of paroxysmal hemoglobinuria. MILTON HANKE

The pain-producing action of the potassium ion. The physical chemistry of inflammation. C. HÄBLER AND R. HUMMEL. *Klin. Wochschr.* 7, 2151-3(1928).—A concn. of K ion in excess of 12 mg. % produces inflammation and pain. Neutral or slightly alkaline Na phosphate buffer solns. are not painful when injected. K phosphate buffer solns. of identical p_H are painful. Acid solns. are always painful. The pain produced by the injection of acid solns. subsides rapidly. The pain produced by K solns. is protracted. Inflamed areas contain acid; but they also contain Na, Ca and K in a ratio such that there is an excess of K. MILTON HANKE

The anti-hemolytic action of liver in the therapy of anemics. L. PONTICACCIA AND D. CAMPANACCI. *Klin. Wochschr.* 7, 2153-4(1928).—The action of a liver diet, in pernicious anemia, is primarily anti-hemolytic because (1) the general condition is improved almost immediately and before the blood picture is changed; (2) the concn. of bilirubin in the blood and of urobilinogen in the urine is decreased; (3) the cholesterol content of the blood is increased. MILTON HANKE

The relationship between the colon bacillus infection of the small intestine and liver therapy in pernicious anemia. NORBERT HENNING. *Klin. Wochschr.* 7, 2190-3(1928).—Liver exts. are not antiseptic. The ingestion of liver exts. appears to have no effect upon the colon bacillus infection of the small intestine in cases of pernicious anemia that are otherwise benefited by the treatment. MILTON HANKE

The action of light on blood. MEYERSTEIN. *Klin. Wochschr.* 7, 2244-5(1928).—Blood corpuscles hemolyze spontaneously when they are allowed to remain for some time suspended in sterile physiol. salt soln. The rate of hemolysis is accelerated by sunlight. The hemolysis time (in days) for various bloods kept in the dark or exposed to sunlight is as follows (sunlight periods are in parentheses): human, 13-14 (5-6); guinea pig, 11-12 (2); mouse, 2-3 (1); pigeon, 15-16 (6-7) and frog, 18 (7). The stability of blood cells in the animal body may be affected by light. MILTON HANKE

The action of the serum of non-castrated males on pregnancy in rabbits. W. BUTOMO. *Klin. Wochschr.* 7, 2253-4(1928).—The injection of serum from male rabbits (or oxen) into pregnant rabbits always leads to disturbances. Injection of the serum during the first 10-16 days of pregnancy leads to an arrestment of the fetal development and a resorption of the uterus contents. After 18 days of pregnancy, some of the fetuses are resorbed. Serum injections that are given during the last stages of pregnancy may lead to abortion or to the birth of fetuses, some of which are alive and some dead. In certain of these cases the live fetuses were all male, the dead ones either female or indeterminate. MILTON HANKE

Nature of natural and acquired immunity. JOHN A. KOLMER. Univ. Pennsylvania. *J. Am. Inst. Homeopathy* 22, 12-23(1929).—A concise, comprehensive survey of modern immunology. JOSEPH S. HEPBURN

Newer knowledge on the relations of the cell to immunological processes. RALPH R. MELLON. Western Penn. Hospital, Pittsburgh. *J. Am. Inst. Homeopathy* 22, 35-45(1929).—A discussion of the role of tissue cells in the processes of immunity. JOSEPH S. HEPBURN

The iodine content of milk, its dependence on iodine content of feeding plants and soil; its relation to goiter. F. KIEFERLE. *Naturwissenschaften* 16, 957-62(1928).—A review. B. J. C. VAN DER HORVEN

The arterial blood in ammonium chloride acidosis. J. B. S. HALDANE, G. C.

LINDER, R. HILTON AND F. R. FRASER. St. Bartholomew's Hosp., London and Cambridge. *J. Physiol.* 65, 412-21(1928).—Exptl. acidosis produced in man by giving large doses of NH_4Cl (20 g. per day) disturbed all the equilibria of acid-base regulation in the arterial blood. CO_2 content and CO_2 tension were less; the reaction was more acid; and the increased hemoglobin indicated that concn. of the blood had occurred. NH_4Cl had a damaging effect on the blood and endothelial cells indicated by (1) an increase in the hyaline leucocytes, (2) an increased tendency of the red cells to hemolyze and (3) a mild grade of subsequent anemia. J. F. LYMAN

Endocrine glands and defence. A. SEITZ. Univ. Leipzig. *Centr. Bakt. Parasitenk.*, I Abt., 109, 115-20(1928).—The removal of the adrenal in rats produced a marked decrease in the phagocytosis of anthrax bacilli, independent of whether the organisms were studied *in vitro* or *in vivo*. Capsule formation does not occur. Simultaneous castration adds nothing to the effects. There is a decided decrease in bactericidal formation against most organisms. There is a neutrophilic leucopenia, a lymphocytosis, and a thrombocytopenia. The serum of adrenalectomized rats gives lower interometer readings than that of normal rats. JOHN T. MYERS

Purification of botulinic toxin. S. HOSoya, G. J. STÉFANOPOULO AND S. MIYATA. *Compt. rend. soc. biol.* 99, 1465-7(1928).—The botulinic toxin may be purified by pptn. with ZnCl_2 and sepn. from its Zn compd. by $(\text{NH}_4)_2\text{S}$. The toxin thus purified gives some of the reactions for higher proteins, and is not pptd. by picric or picrolonic acids. Further study of this purified toxin is in progress. L. W. RIGGS

Natural and acquired immunity against tetanus intoxication in the fowl. G. RAMON. *Compt. rend. soc. biol.* 99, 1473-5(1928).—The fowl shows a marked but not unlimited resistance to tetanus intoxication, and is capable of producing abundant quantities of sp. antitoxin when injected with tetanic antigen (toxin or antitoxin), thereby acquiring an artificial immunity in addn. to its natural immunity. These 2 immunities concur in protecting the fowl against tetanus intoxication. Passage of tetanus toxin and antitoxin from the fowl to the egg and to the chick. *Ibid* 1476-8.—Following the injection of tetanus toxin in the fowl a sp. antitoxin is formed which passes readily from the blood to the vitellus of the egg and not to the albumin. The tetanus antitoxin thus concealed in the yellow of the fertilized egg is recovered in the blood of the chick hatched from that egg. L. W. RIGGS

Value of the azotemic ratio in the normal state. MARCEL LABBÉ, F. NEPVEUX AND A. HIERNAUX. *Compt. rend. soc. biol.* 99, 1492-3(1928).—In detg. the N ratio the samples of blood should be taken after a 12 hr. fast. Total N and urea N should be detd. in the desalbuminated serum in preference to desalbuminated total blood. Desalbumination is best made with 20% $\text{CCl}_3\text{CO}_2\text{H}$ and at the isoelec. point of the albumen. The quantity of the sample should be sufficient to give 20 cc. of filtrate from the $\text{CCl}_3\text{CO}_2\text{H}$ ppt. for the detn. of total N by the macrochemical method of Kjeldahl. Methyl orange indicator should be used in the final titration. Urea was detd. by the method of Fosse. In 7 normal subjects the urea N/total N ranged from 40 to 48%. Azotemic ratio in nephritics and in subjects with liver disease. *Ibid* 1493-5.—In all nephritics the ratio urea N/total N of the blood serum ranged from 55.8 to 95%, and in 10 subjects with cirrhosis of the liver the range was from 15 to 37%. L. W. RIGGS

Experimental uremia and the chlorine content of the cortex. F. LEÖVEY AND E. KÉKÉLI-PRONIVS. Univ. Budapest. *Arch. exptl. Path. Pharm.* 138, 372-8(1928).—During Cl hunger the cortex loses but 14.45% of its Cl content while the white matter loses 55%. When an abundance of Cl is administered after ligation of the ureters the gray matter takes up almost three times as much Cl as does the white substance (111.9% and 56.02%). In exptl. uremia with ligation of the ureters the pathologic state, although qualitatively unchanged, is reduced in duration by half if an abundance of Cl is given. G. H. S.

Endemic goiter in rabbits. III. Effect of administration of iodine. BRUCE WEBSTER AND ALAN M. CHESNEY. Johns Hopkins Med. School. *Bull. Johns Hopkins Hosp.* 43, 291-308(1928).—An excess of I administered to rabbits caused a temporary lowering of the metabolic rate, which gradually returned to normal when the I was discontinued. Doses of 0.06 cc. Lugol's soln. given daily produced in the normal thyroid gland a diffuse out-pouring of colloid with a flattening of the alveolar epithelium and a preponderance of the colloid cells. Doses of 0.03-0.06 cc. Lugol's soln. or 25 mg KI daily when administered to goitrous rabbits caused a marked increase in the metabolic rate, rapid emaciation and usually death. I tended to effect involution of the hyperplastic thyroid gland with a lowering of the alveolar epithelium. R. C. W.

The Nobel reaction and the p_n in normal and pathological cerebrospinal fluids. G. HALPER. Univ. of Padua. *Münch. med. Wochschr.* 75, 1628(1928).—On the basis

of the results obtained by other investigators, H. studied the colorimetric ninhydrin reaction to det. if it is possible to detect an increase in the protein content of the spinal fluid by this method. He examd. 60 children with serious diseases of the nervous system and 30 normal children. The strength of the reaction was parallel with the protein content of the spinal fluid. When the protein content was within the normal limits (0.02%), the reaction was always negative. Using the Michaelis method he found that the p_H of the spinal fluid varied from 7.9 to 8.2. In epidemic cerebrospinal meningitis and suppurative meningitis the p_H approaches the neutral point. In tuberculous meningitis this displacement toward the neutral point is very slight, but always detectable. Similar displacement was observed in many of the so-called meningisms of the different diseases.

Possible action of drugs as antigens and the relation of such possible action to homeopathic prescribing. CONRAD WESSELHOEFT. *J. Am. Inst. Homeopathy* 22, 24-34(1929).—A discussion of the possible role of drugs in the production of antibodies.

JOSEPH S. HEPBURN

Physiology and pharmacology of the isolated iris. I. EMIL LEVKO. *Med. Doswiadczenia i Spoleczna* 7, 311-54, 355-8(English).—The mechanism of the contraction and dilatation of the pupil and relaxing action of adrenaline, ergotamine, ephedrine, tyramine, cocaine, pilocarpine, arecoline, physostigmine, atropine, histamine and BaCl₂ solns. on the excised sphincter muscle of the iris is investigated on the basis of the numerous pharmacol. expts. and it is detd. that the dilating mechanism of the pupil is an inhibitory action of the sympathetic nerve endings on the sphincter muscle. Bibliography.

JAROSLAV KUČERA

The photodynamic action of hematoporphyrin. ETHELBERTA N. RASK AND W. H. HOWELL. Johns Hopkins Univ. *Am. J. Physiol.* 84, 363-77(1928).—Hematoporphyrin injected into dogs sensitized the animals to light, resulting on exposure in cutaneous irritation, motor excitation, erythema and edema of the skin and hyperpnea followed finally by cutaneous cyanosis, loss of sensibility, stupor and death. An isolated illuminated turtle heart perfused with Ringer soln. contg. hematoporphyrin stopped in a contracted state. Illumination of the hematoporphyrin soln. alone had no injurious effect on the heart kept in the dark. The fatal effects in dogs were due to the fall in blood pressure and the vascular collapse was not due to toxic substances but to paralysis of the cutaneous circulation. No significant change in blood sugar or in the blood acidity could be detected.

J. F. LYMAN

Properties of separated active principles of the pituitary (posterior lobe). J. H. GADDUM. Natl. Inst. Med. Res. *J. Physiol.* 65, 434-40(1928).—Com. oxytocin, in addn. to its effect on the uterus, had a depressor effect on blood pressure which could not have been due to histamine. Vasopressin, in addn. to its effect on blood pressure and on the kidney, had a sp. stimulating action on the bowel of the rabbit and a dilator action on the melanophores of the frog.

J. F. LYMAN

The action of ammonium salts. MARY WHELAN, MINARD F. JACOBS AND NORMAN M. KEITH. Proc. Am. Physiol. Soc., *Am. J. Physiol.* 81, 513(1927).—When NH₄ salts were administered to animals some of the NH₄ was quickly synthesized to urea, leaving the liberated anion to increase the acidity of the tissues or to be disposed of by oxidation or combination. Inorg. acids and benzoic acid and their NH₄ salts caused an acidosis; while acetic acid or AcONH₄ had no such effect.

J. F. LYMAN

Tolerance of the animal organism for sodium chloride waters. H. VELU. *Compt. rend. soc. biol.* 99, 1481-2(1928).—Beef animals weighing about 300 kg. were able to tolerate about 1 g. of NaCl per kg. of live wt. Man tolerates about 0.5 g. of NaCl per kg. A further study of this question is promised.

L. W. RIGGS

Action of encephalic anemia on the nerve centers and cardiac, gastric and enteric vagi, with the isolated head. B. A. HOUSSAY AND E. HUG. *Compt. rend. soc. biol.* 99, 1503-6(1928).—Action of encephalic asphyxia on the respiratory, cardio-regulator gastric and enteric centers. *Ibid* 1506-7.—Direct and reflex action of nicotine and of lobeline on the respiratory centers and the cardio-regulator, gastric and enteric vagi. *Ibid* 1508-9.—Heyman's technic of the isolated head was used. In general there was at first an inhibition followed by a reinforcement. Nicotin injected into the decapitated trunk caused an inhibition for 1 to 2 min. of the gastrointestinal movements by direct action and by the discharge of adrenaline. Lobeline caused the same effects as nicotine but its action was less intense for the same doses. Action of ypomorphine and crotalus

venom on respiratory centers and vagi in the technic of the isolated head. *Ibid* 1509-11.—With 3 to 5 mg. doses of the venom there was at first apnea then dyspnea followed by depression or cessation of the respiration. In all cases there was a bradycardia and often a brief arrest of the heart in the decapitated trunk. There was always an inhibition of gastro-enteric movements for 30 to 90 sec. followed by a reinforcement of these movements. The results show that the venom of *Crotalus terrificus* has an intense action on the central nervous system. L. W. RIGGS

Oligodynamic activity of distilled water caused by metallic silver. R. WERNICKE AND F. MODERN. *Compt. rend. soc. biol.* 99, 1519-20(1928); cf. *C. A.* 21, 2716.—Distd. water, rendered oligodynamic by contact with metallic Ag, contains at least 0.0005 mg per cc. of ionized Ag. This activated water loses its power after a prolonged electrolysis in which the Ag is deposited on the cathode. The oligodynamic activity of water after contact with Ag is due to the ionization of the metal. L. W. RIGGS

Hemodynamic action of adrenaline and of choline in suprarenalectomized dogs. E. TROILO. *Compt. rend. soc. biol.* 99, 1521-2(1928).—In suprarenalectomized dogs the threshold of action of adrenaline is lowered, and the action of the drug is more intense and more prolonged. A dog weighing 31 kg. reacted to 1 cc. of a 1 to 8 million soln. of adrenaline. The effect of suprarenalectomy on the action of choline was to retard its action and diminish its intensity. L. W. RIGGS

Discharge of choline into the blood after the injection of adrenaline. G. VIALE AND T. COMBES. *Compt. rend. soc. biol.* 99, 1524(1928).—Expts. with guinea pigs proved that the injection of 1 cc. of a 1 to 10,000 soln. of adrenaline produced an increase of about 7 mg. per l. of choline in the blood in 4 out of 5 cases. L. W. RIGGS

Influence of ergotamine on alimentary hyperglucemia in normal and diabetic subjects. EDUARDO COELHO AND J. CANDIDO DE OLIVEIRA. *Compt. rend. soc. biol.* 99, 1527-30(1928).—Ergotamine lowers the alimentary hyperglucemia in both normal and diabetic subjects, and raises the tolerance for carbohydrates. It also lowers adrenaline hyperglucemia. L. W. RIGGS

Action of insulin on the external secretion of the pancreas in the case of pancreatic fistula. FERNANDO PONSECA AND CARLOS TRINCAO. *Compt. rend. soc. biol.* 99, 1532-3(1928).—Expts. with human subjects showed that insulin increased quantitatively the external secretion of the pancreas when given with a mixed diet, but does not affect the external pancreatic secretion under fasting conditions. Action of certain drugs upon the external secretion of the human pancreas. *Ibid* 1533-5.—Tests with a patient having a pancreatic fistula proved that odor or sight of food, pituitrin, atropine, pilocarpine and ergotamine increased the flow from the fistula. Pituitrin, atropine and ergotamine decreased the quantity of enzymes in the juice, while pilocarpine increased the enzymes. Adrenaline decreased both the flow and the enzymes, while ephedrine and ephedrine diminished the secretion without changing the enzymes. L. W. R.

Action of ergotamine on glucemia. CARLOS TRINCAO. *Compt. rend. soc. biol.* 99, 1538-40(1928).—From a study of 4 diabetic cases, it is concluded that in general ergotamine does not promote the action of insulin, though exceptionally it appears to do so. L. W. RIGGS

Role of colloids in the anagototoxic power of mineral waters. P. L. VIOLLE. *Compt. rend. soc. biol.* 99, 1723-4(1928); cf. Billard, *C. A.* 21, 2007.—Expts. indicated that the colloids played only an accessory role in the anagototoxic action of mineral waters. Crystalloids played the principal role. L. W. RIGGS

Plasmoquine (plasmochine). C. M. HASSELMANN AND MARGARET HASSELMANN-KAHLER. *Philippine J. Sci.* 37, 75-119(1928); cf. Hürlein, *C. A.* 21, 800; Roehl, *C. A.* 21, 963; Barman and Smits, *C. A.* 21, 3085.—Plasmoquine, said to be *n*-diethyl- α -ammonio-pentyl-8-amino-6-methoxyquinoline, was administered in 90 cases of naturally acquired malarial infection. In 40 of these cases, which were tertian infections, the patients were freed from parasites in 2 to 6 days after treatment. In 31 other patients with simple aestival-autumnal infections, and receiving "plasmoquine compd." (a mixt. of 0.01 g. plasmoquine and 0.125 g. quinine sulfate) the parasites were absent in 2 to 10 days after the beginning of treatment. In all cases splenic enlargement rapidly decreased. In double infections treated with plasmoquine certain schizonts appeared but never the sexual forms. In these cases the treatment was continued with plasmoquine compd. Relapses were few as compared to those after quinine medication. There are 60 references to the literature. L. W. RIGGS

Insulin as an aid in pulmonary tuberculosis. GIUSEPPE PACI. *Rass. clin. terap. sci. affm* 27, 341-6(1928).—P. practiced application of insulin in 8 afebrile patients suffering from pulmonary tuberculosis. In 6 of these he noted a conspicuous increase in wt. and improvement of the general condition. In the 7th and 8th case insulin had

a beneficial influence, though the increase in wt. was not permanent. This was due to the fact that these 2 patients also suffered from other grave complications. In all the other cases the increase in wt. was permanent and a further increase was often noted even after stopping the insulin treatment. As a rule 30 units per day were given for about 1 month after slowly building up the tolerance for the hormone with small doses. The insulin was injected in 2 doses about 1 hr. before meals. There were no symptoms indicating hypoglycemia except, occasionally, a strong desire for food and a slight indisposition. Local reactions, urticaria or gastrointestinal disturbances of importance were not observed; the temp. remained normal. G. SCHWOCH

The treatment of epilepsy and the boron preparations. ALBERTO LUNGAROTTI. *Rass. clin. terap. sci. affini* 27, 347-53(1928).—A historical review of epilepsy and the drugs used for its treatment, particularly Br and B preps.; also clinical reports on *Liquor Sacer Serono*, which has a K boro-tartrate as its base. G. SCHWOCH

Has "Bayer 205" an effect upon anaphylactic shock? ERNST WIECHMANN AND FRITZ KOCH. Univ. Köln. *Arch. expil. Path. Pharm.* 132, 118-21(1928).—No effect was observed. G. H. S.

Relation of calcium to the occurrence of narcosis and irritability states in decorticate and completely decerebrate animals. HANS FISCHER. Univ. Zurich. *Arch. expil. Path. Pharm.* 138, 169-89(1928).—The changes in blood Ca occurring in the normal animal during sleep and in narcosis take place in the same way in dogs deprived of cortex. During sleep or narcosis the Ca is diminished; with cerebral stimulation it is increased. If the entire brain is removed no change in the Ca of the blood occurs. The reduction in Ca during sleep and narcosis is reflected in a corresponding increase in K, again exhibiting the antagonism between these 2 elements. G. H. S.

Effect of scopolamine in combination with cyanide, carbon monoxide and reduced air pressure. U. G. BIJLSMA AND J. E. BROUWER. *Arch. expil. Path. Pharm.* 138, 190-207(1928).—Preliminary treatment with scopolamine prevents the development of KCN or CO convulsions, probably because, just as by reduced O tension, the lack of O in the blood in CO intoxication and in the tissues in KCN intoxication enhance the narcotizing effect of the scopolamine. Thus, the cerebral motor centers are depressed, and with larger doses the cord centers also. G. H. S.

Mechanism of the action of ephedrine and differences in the intensity of action of its isomers. OTTO SCHAUMANN. *Arch. expil. Path. Pharm.* 138, 208-18(1928). The effect of ephedrine upon blood pressure is due entirely to its effect upon the peripheral vessels, which become sensitized to suprarenine by ephedrine. Cocaine and anesthetics of the novocaine group exhibit similar phenomena. The *l*-form of ephedrine is definitely more active than is the *d*-form, while the racemic form is but half as effective as the *l*-form. G. H. S.

Reversal of the action of the vagus and the splanchnic on intestinal motility by potassium and calcium. W. BRANDHENDLER. *Arch. expil. Path. Pharm.* 138, 219-27(1928).—The effect of stimulation of both nerves of the intestine is increased or diminished by the intravenous injection of K or Ca. There is a reversal of effect in that stimulation of the vagus causes an inhibition, of the splanchnic an increase in intestinal motility. G. H. S.

Action of poisons on striated intestinal muscle of the tench. ERNEST FREY. Univ. Rostock. *Arch. expil. Path. Pharm.* 138, 228-39(1928).—The intestinal musculature is composed of both striated and smooth muscle, both of which take part in contraction, each responsible for a distinct contraction phase sep'd. by an interval. Ale causes a reduction in the contractions assoc'd. with the first phase, that due to the striated muscle, and a very great increase in that related to the second phase. With chloral hydrate the effect is reversed. Histamine, adrenaline, acetylcholine, pilocarpine, physostigmine and morphine favor the action of the smooth portion of the muscle. The action of papaverine and that of quinine are det'd. by the concn. used. Caffeine causes contraction. Camphor exerts a far greater effect on the smooth than on the striated muscle. Curare influences the striated portion, atropine the smooth muscle. The contraction waves assoc'd. with the smooth muscle are favored by pilocarpine and physostigmine, inhibited by adrenaline. G. H. S.

Increased activity in the effects of some alkaloids. ERNO ANNAU AND IMRE SÁRKÁNY. *Arch. expil. Path. Pharm.* 138, 240-4(1928).—See C. A. 23, 647. G. H. S.

Diuretic effect of organic mercury compounds. B. v. ISSEKUTZ AND F. v. VÉGH. *Arch. expil. Path. Pharm.* 138, 245-55(1928).—Among the various comp'ds. tested toxicity ranged all the way from those as toxic as HgCl₂ to those having about 1/10 as great an intoxicating power. Diuretic action is assoc'd. with a definite chem. structure. G. H. S.

Action of narcotics on nerves. S. FLAMM. Univ. Leipzig. *Arch. exper. Path. Pharm.* 138, 257-75(1928).—Tabulated data covering the paralytic and intoxicating effects induced by a series of alcs. by urethan, brominal, neuronal, hedonal and chloral hydrate upon frog nerve. G. H. S.

Analysis of the differential action of heart poisons. VI. Effect of acetaldehyde on the frog heart. BRUNO KISCH. Univ. Köln a. Rh. *Arch. exper. Path. Pharm.* 138, 329-38(1928).—Acetaldehyde retards stimulus formation and with higher concns. or with repeated exposure to lower concns. arrest takes place. Active doses of acetaldehyde always exert a negative inotropic effect. G. H. S.

A contribution to the chemistry, pharmacology and therapeutics of *Agave salmiana*. G. G. COLIN. Chem. Lab. Dept. Pharmacol., Mexico. *J. Am. Pharm. Assocn.* 17, 1182-9(1928).—The juice obtained by expression fermented rapidly unless sterilized. The crude liquid contains a hemolytic saponin. A highly irritant substance was found in the stems. Two cryst. substances were obtained from the juice, one by evapn. in an acid medium and the other by neutralizing and then adding an excess of EtOH. The acid ppt. contains 15% of Ca but the identity of the 2 ppts. was not established. A did. präpn. of the principle was given to rabbits hypodermically. No effects were observed. Humans were given hypodermic injections of the soln. together with stovaine to prevent pain. No toxic effects were noted. Clinically 30 cases of syphilis in various stages were treated. Some cases which had resisted the usual treatment responded well under *Agave* while others showed no improvement. Cases with secondary ulcers responded best. The effect on the Wassermann test was uncertain and in some instances no relation could be established between clinical improvement and modification in the Wassermann reaction. As a whole the results are inconclusive. L. E. W.

Derivatives of mono- and diamino-hydroxyphenylarsonic acids (FISHER, RAIZISS)

10.

I—ZOÖLOGY

R. A. GORTNER

Iodine compounds in fish products. G. LUNDE AND K. CLOSS. *Tids. Kem. Bergeven* 8, 33-4(1928).—Sea fishes contain a relatively large amt. of I (3.2-4.2 mg. per kg.) and most of this remains in the dried and salted product. A portion of the total I can be extd. by shaking an acidified aq. ext. of the fish with chloroform (lipoid I) and a little is present in the form of protein substances (protein I), but the greater portion is in the form of unknown org. I compds., insol. in water. Deep-sea fishes contain more I than those living near the surface: dried haddock contains 6 times as much I as coalfish, and 20 times as much as herring. In the deep-sea prawn the I appears to be mainly concd. in the skin and internal organs, the muscles being relatively poor in this constituent. B. C. A.

The metabolism of insects. MARY HONORA SAYLE. *Quart. Rev. Biol.* 3, 542-53 (1928). A review. J. B. BROWN

Action of potassium on the dorsal vessel of the larva of the fly functioning in an artificial medium. ROBERT LEVY. *Compt. rend. soc. biol.* 99, 1485-6(1928).—K has a toxic action on the dorsal vessel, and if added in excess arrests the ventricle in systole, the same as in previous expts. with *Daphnia*. L. W. RIGGS

Effect of some iodine compounds upon frog larvae. J. SCHWAIBOLD. *Arch. ges. Physiol.* (Pflüger's) 220, 1-10(1928).—Although inorganically combined I does not cause a thyreomic effect upon metamorphosis it does hasten the development of frog larvae to a slight extent. No more marked effect results if the larvae are fed upon the milk of cows to which inorg. I has been given. Only slight influence of I is exhibited when in combination with protein, or when NaI is given in conjunction with tyrosine. G. H. S.

Studies on oils obtained from insects. I. Oils obtained from fireflies, locusts and grasshoppers. MITSUMARU TSUJIMOTO. Inst. Tokyo Ind. Research. *Bull. Ind. Research* (Tokyo) 23 [3], 65-78(1928).—(1) *Oils from butterflies*.—160 fireflies (wt. 179 g.) consisting of a mixt. of *Luciola ritticollis* and *Luciola parva* were powd. and extd. with EtO in a Soxhlet app., 0.8073 g. (4.8%) of fats being obtained. The oil is orange-yellow, viscous, has a bad odor. I_2 no. is 116. When sapond. it yielded 87% fatty acid and unsaponifiable substance. The former m. 36°, neutralization value 179.2, I_2 value (Wies' method) 110.7; forms 17.9% of an Et₂O-insol. Br. deriv., $C_{18}H_{33}O_2Br$ of $C_{18}H_{31}O_2$ ($C_nH_{2n-5}O_2$ series). The unsaponifiable substance contained a white powder m. 154-5°, and a sterol. In the second expt. the oils obtained from the parts of head and breast, and of the abdomen were separately treated. The former has a higher

I₂ no. The latter contains a highly unsatd. fatty acid m. 37.5–8°, neutralization value 199.5, I₂ no. 100.7; and 14% of unsaponifiable substance. This investigation was made because some relation between the light production and highly unsatd. fatty acid might be expected. (2) *Oils from locusts*.—3% of oil was extd. with Et₂O, d₄₀¹⁸ 0.9688, acid no. 44.3, sapon. no. 171.5, I₂ no. (Wijs' method) 122.6, unsaponifiable substance 15.75%. Linoleic, oleic, palmitic and stearic acids were identified. 44.1% of the unsaponifiable substance is a sterol, the remainder being an orange-yellow semi-solid which is colored dirty blue by a CHCl₃ soln. of SbCl₅. (3) *Oils from grasshoppers*.—*Acheta mitrata* was dried in a steam oven, and 2.4% of oil was extd. The characteristic consts. are (with impurities) d₄₀^{19.6} 0.9312, sapon. no. 181.5, I₂ no. 116, unsaponifiable matter 11.32%. The fatty acids consist of linoleic and other acids of the oleic series. The unsaponifiable matter contains 45.45% of sterols. K. SOMEYA

12—FOODS

F. C. BLANCK AND H. A. LEPPER

Old and new foods and food products. W. PEYER AND H. IMHOF. Halle. *Apoth. Ztg.* 44, 120–2, 136–8(1929).—A descriptive summary of the chief constituents of certain foods and their products as rye, oats, wheat, potato, meat exts., yeast preps., etc. W. O. E.

Know your foods. II. Graham bread. H. A. SCHUETTE. Univ. of Wisconsin. *J. Chem. Education* 6, 59–64(1929); cf. *C. A.* 23, 913. E. J. C.

New investigations concerning low pasteurization of milk and a reaction to control the degree of heating. S. ORLA-JENSEN. *Kemisk Maanedssblad* 9, 41(1928).—Milk heated 5 min. to 68° does not cream, whereas milk heated 30 min. to 63° does cream almost as easily as non-heated milk. The lowest temp. at which the creaming no longer takes place is used as upper limit for the domain of "low-pasteurization." Milk which has been heated to 63° creams more slowly if dild. by water, whereas non-heated milk creams more swiftly. The temp. for which the creaming is neither hastened nor retarded on diln. is the lower limit. Low-pasteurized milk, then, should be able to cream and should cream more slowly if dild. by water. KRISTIAN HØJENDAHL

New investigations concerning low pasteurization of milk and a reaction to control the degree of heating. S. ORLA-JENSEN. *Mælkeritidende* 41, 603(1928); cf. preceding abstr.—The lower limit is about 62°. The author discusses at length why creaming is destroyed by heating. Tables are given for the effects of temp. and certain addns. on creaming. KRISTIAN HØJENDAHL

The utilization of whey. M. A. F. BARNETT. *New Zealand J. Sci. Tech.* 10, 163–6(1928).—A certain amt. of whey produced at present in New Zealand is used for feeding pigs, but in its present highly dil. state, it is rather detrimental as such, increasing in acidity if kept for any length of time, causing a strong laxative action, while very large quantities must be consumed before the animal gets the benefit of an appreciable amt. of solids. Evapg. down to about 60% solids is a considerable improvement, and cost figures are given in detail. A typical analysis of the resulting paste shows: H₂O 49.0, protein 6, ash (mineral) 4.7, acidity (as lactic acid) 1.2, fat 0.3 and milk sugar (by difference) 38.8%. Trials for use as pig feed and its food value are in progress, and the results will be published in a later issue. J. C. JURKENS

The use of fats in baking. M. B. GRAFF. Procter and Gamble Lab. *Oil and Fat Industries* 5, 352 5(1928).—The action of fats in baking presents many unsolved problems. Bread made with 2.5 to 3% fat is preferable to that with more or less. In pie crust, fat probably seps. the layers of gluten. In rich cakes it has a leavening effect from the incorporation of air in creaming. In plain cakes it is used to produce tenderness and a more lasting freshness. In cookies, biscuits and crackers, the consistency and chem. compn. of the fat affect the tenderness of the product. AMY LEVESCONTE

The proteins of fish. JOHN L. ROSEDALE. Malaya Section, Inst. of Chem., Gt. Brit. and Ireland, Singapore. *Reprint of Lecture* July 19, 1928, 5 pp.—While the amino acids of the proteins of plants and meat have been extensively studied, little attention has been given to fish proteins. By use of Plimmer and Rosedale's modification (*C. A.* 16, 1980) of the Van Slyke method for amino acid detn., several fish proteins were found to have the following % compn.: Red snapper, amide N, 6; humin N, 1; diamino total N, 30; monoamino total N, 64. Thread-fin, amide, 7; humin 1, diamino, 28; monoamino, 63. Tunny, amide, 4; humin, 0.75, diamino, 23; and mono-

amino, 69. Carp, amide, 7; humin, 1; diamino, 27; monoamino, 64. In female fish roes (species not stated), the histones obtained by extrn. with EtOH and pptn. as a sulfate contained amide N, 15; humin N, 6; diamino total N, 48; monoamino total N, 32; arginine, 37; histidine, 7; and lysine, 4%. A portion coagulated by heat closely resembled muscle protein. The male roes contained the following per cent of amino acid fractions: amide, 15; humin, 9; diamino total N, 49; monoamino total N, 31; arginine, 41; histidine, 6; and lysine, 2. The time of hydrolysis was varied from 1 to 100 hrs., small differences being noted in 10 hrs. in the diamino and monoamino N detns. in carp and tunny. In tunny, the arginine % of total N varied from 18 after 1 hr. to only 9 after 30 hrs. In the carp, the arginine reached a const. value after 10 hrs.

C. R. F.

Dates in glass. V. CAHALIN. Monrovia Valley Pkg. Corp., Calif. *Glass Container* 8, No. 2, 7-9(1928).—Calif. dates before packing are treated in a vacuum fumigator with CS_2 gas for 2 hrs. to destroy insects and worms. Dates are spray-washed, air dried, packed into jars, sealed under vacuum and given a heat treatment of 5-10 min. at 100° . For package dates, the H_2O content is controlled at approx. 18%.

C. R. F.

Boric acid in oranges. J. T. DUNN AND H. CHARLES BLOXAM. *Analyst* 54, 28, 9(1929).—In 7 samples of oranges 0.14-0.56 grains of H_3BO_3 was found per lb. of pulp and 0.03-2.31 grains per lb. of peel. It is believed that these quantities of H_3BO_3 are normal and do not indicate the use of preservative.

W. T. H.

Natural occurrence of boron compounds in fruits and vegetable products. A. SCOTT DODD. *Analyst* 54, 15-22(1929).—The analysis of some 50 fruits and vegetables showed the presence of 0-0.025% B_2O_3 . This is much less than the minimum quantity which would be of any real value as a preservative. If, therefore, any article of food contains more than 0.1% of B_2O_3 it is reasonable to conclude that preservative has been added.

W. T. H.

Injury to onions and fruits caused by exposure to ammonia. G. B. RAMSEY AND I. F. BUTLER. Bureau of Plant Industry, Wash., D. C. *J. Agr. Research* 37, 339-38(1928).—Brownish and greenish black spots on onions, apples, pears, peaches and bananas that have been kept in storage could not be associated with any causative organism. This type of injury was produced experimentally by exposure to NH_3 . The extent of injury was detd. by the percentage of NH_3 in the air, the relative humidity and the duration of the exposure. Variations in temp. had little effect. The yellow, brown and red pigments become dark brown or greenish black when exposed to NH_3 fumes. The injury in very dil. gas is merely a blemish but in strong concns. it may involve softening and discoloration of the entire fruit.

A. L. MEHRING

The determination of traces of iodine. II. Iodine in vegetables. J. F. McCLENDON AND FOR E. REMINGTON. Minnesota Univ. and Med. College of S. Carolina. *J. Am. Chem. Soc.* 51, 394-9(1929); cf. *C. A.* 22, 1745.—From 5 to 10 kg. of vegetables are ground, dried to a putty, made into sticks 50 by 24 mm., and dried again. These are led into a combustion tube with O, and burned. Volatile chlorides and iodides are absorbed by NaOH in wash bottles and a Cottrell precipitator. The temp. is kept below 450° and the ash must be alk. to prevent fusion. In cereals, Ca lactate is added. Iodine from the ash, wash bottles, and precipitator is detd. colorimetrically in CCl_4 .

AMY LEVESCONTE

"Finger and toe" experiments in Mid-Wales involving the use of resistant varieties of swedes. D. WALTERS DAVIES, MOSES GRIFFITH AND GWILYM EVANS. Univ. Coll., Aberystwyth. *Welsh J. Agr.* 4, 295-303(1928).—Figures are given on the moisture, dry matter, protein, ash, P_2O_5 and CaO contents of 6 varieties of swedes grown in Mid Wales.

K. D. JACOB

Recent advances in science: Agriculture: Animal nutrition. HERBERT E. WEDMAN. Univ. Cambridge. *Science Progress* 23, 432-8(1929).—A review of recent work on the evaluation of feeding stuffs for milk and fat production in the animal, the nutritive value of sugar-beet by-products, and the food requirements of farm animals.

JOSEPH S. HEPBURN

Further studies on the chemical composition and nutritive value of yellow oats and white oats. F. HONCAMP, W. SCHRAMM AND H. STOTZ. *Z. Tierzücht. Züchtungsbiol.* 11, 434-44(1928).—The two varieties of oats are similar in composition and feeding value. Coarsely ground oats are better digested by sheep than whole oats.

L. A. MAYNARD

Protein decomposition in silage formation. BRUNO REETZ. *Z. Tierzücht. Züchtungsbiol.* 13, 93-119(1928).—In normal silage formation the protein decompn. occurs as a result of the action of the plant enzymes and not as a result of bacterial action.

Small amts. of acid and CO_2 result from intramol. changes such as respiration and from enzyme action. A content of 1.5% lactic acid and above injures the activity of the proteolytic enzymes. A smaller injurious effect is caused by 10% toluene. The CO_2 formed in the absence of bacterial action is 0.02 to 0.05 g. per g. dry substance, an amt. which is about one-tenth that observed in normal fermentation. L. A. M.

Solubility relationships of lactose-sucrose solutions (PETER) 2. The relation of food to the composition of milk (DAVIES, PROVAN) 11E. Effect of distilled water upon the tendency to colony formation upon Petri plates (MUDGE, LAWLER) 11C. Perfumery chemicals and flavorings (BOAKE, ROBERTS & Co.) 17. Treating garbage (U. S. pat. 1,700,608) 14. Apparatus for pasteurizing milk, etc., in bulk (U. S. pat. 1,701,777) 1. Apparatus for separating hard substances such as pips from fruit pulp (Fr. pat. 643,557) 1. Acidity-testing apparatus (U. S. pat. 1,700,655) 1. Yeast preparation (U. S. pat. 1,701,200) 16. Sausage casing made of regenerated cellulose (Brit. pat. 292,582) 23. Apparatus for irradiating milk, etc. (Austrian pat. 111,853) 1.

Preserving foodstuffs. JEAN E. W. REEH. Fr. 643,666, Nov. 8, 1927. Foodstuffs to be treated with a freezing liquid are first coated with a liquid, the freezing point of which is higher than that of the freezing liquid, so that the foodstuffs become protected by an envelope.

Treating foods to develop antirachitic properties. A. KNUDSON (to British Thomson-Houston Co., Ltd.). Brit. 292,926, June 24, 1927. Foods are treated with high-velocity electrons such as those from a high-voltage cathode-ray tube. Among the materials treated are mentioned: "breakfast foods," flour, cereals, yeast, starch, cholesterol (as to which an example is given), olive oil, cottonseed oil and other oils, "chicken and other animal foods."

Food product (salad dressing). WILLIAM D. RICHARDSON and ROY C. NEWTON (to Swift & Co.). U. S. 1,701,084, Feb. 5. A blend of oils and fats normally of solid consistency together with spices, salt, vinegar, etc., contains the normally solid blend of oils and fats in the form of minute irregular particles intimately distributed throughout the dressing; by stirring with a liquid such as oil, water, milk and cream the compn may be brought to a suitable fluid condition for use as a liquid salad dressing. U. S. 1,701,085 also relates to similar products.

Food product from yeast. MARTIN NILSSON (to The Fleischmann Co.). U. S. 1,701,081, Feb. 5. Compressed yeast is partially dried (suitably to a moisture content of about 55% at a temp. not substantially in excess of 30°) and admixed with sugar material, such as sucrose, until a sirupy consistency is obtained. The product may suitably have a moisture content of about 20% and a sugar content of about 60%.

Bread. JEAN MATTI (to Augmentine Holding S. A.). U. S. 1,701,580, Feb. 12. See Brit. 266,967 (C. A. 22, 830).

Apparatus for treating milk with ultra-violet rays. FRANZ HOFFMANN. Fr. 643,254, Oct. 31, 1927.

Maturing milk curds. BYK GULDENWERKE CHEMISCHE FABRIK A.-G. Ger. 470,290, May 13, 1925. The process is accelerated by treating the curds with a mixt of bacteria, salt, and compds. contg. the NH_4 group or the amino or amido groups or the disintegration products of albumin. A suitable mixt. contains 30% amino acid, 20% amide compd., 9% NH_4 salt, 40% NaCl , and 1% bacteria. A list of bacteria for various types of cheese is given.

Cheese. AUGUSTE M. QUÉX. Fr. 643,128, Oct. 20, 1927. Cheese is kept from contact with air by dipping it in a bath contg. beeswax 20-30, refined paraffin 30-40, beef suet 15-20, fish gelatin 15-20, and starch 3-5%.

Wrapping cheese. STANIOLFABRIK BURGDORF A.-G. Brit. 292,162, June 17, 1927. Metal foil used for wrapping is coated with an alc. soln. of bleached colorless shellac to which salicylic acid may be added.

Apparatus for freezing packaged meats or other foods, etc. C. BIRDSEYE (to General Foods Co.). Brit. 292,457, June 18, 1927.

Continuous system for preparing cream fondant and its admixtures for confectionery. R. HEAD, C. CLAY, BAKER PERKINS, LTD., and ANCIENS ÉTABLISSEMENTS A. Savy JEANJEAN ET CIE SOC. ANON. Brit. 292,237, March 15, 1927.

Confection comprising gluten. LEON W. STETSON. U. S. 1,700,387, Jan. 29. Gluten such as that used for chewing "gums" is maintained in a substantially plastic and tenacious condition by use of a binder such as hydrogenated peanut oil and glucose.

Treating fruit with paraffin and oil. HOMER C. RICKERTS (to Brodex Co.). U. S.

1,700,908, Feb. 5. An emulsion-like mixt. of creamy consistency comprising paraffin and a refined mineral oil is agitated and immediately applied to fruits such as grapefruit, oranges, lemons, or tangerines and rubbed over the surface to produce a film-like coating. An app. is described. Cf. *C. A.* 23, 652.

Antiseptic material for packing fruits. HENRY BLUMENBERG, JR. U. S. 1,702,103, Feb. 12. Cellular material such as kieselguhr, sawdust, rice hulls or granular C is assocd. with CaF_2 and with an NH_4 salt such as $(\text{NH}_4)_2\text{SO}_4$ capable of reacting with the CaF_2 to form NH_4F .

Pectin. WILLIAM A. BENDER (to Douglas Packing Co., Ltd.). Can. 286,300, Jan. 8, 1929. Saccharine juice is removed from fruit, the fruit pulp is treated with a weak org. acid soln. (as lactic) to obtain the pectin soln., this soln. is treated with solid casein, the clear liquor sepd. from the sediment, the clarified liquor treated with a diastatic enzyme, and then with activated C, and filtered and concd. *in vacuo* and the pectin pptd.

Live-stock feed. CHARLES R. MABEE (to the Mabee Patents Corp.). Can. 286,315, Jan. 8, 1929. Farm roughage is moistened with an aq. admixture contg. approx. 1–1.2% of a compn. contg. $\text{Ca}(\text{OH})_2$, $\text{Mg}(\text{OH})_2$, NaCl and S and is subjected to the action of a ferment.

Live-stock feed. CHARLES R. MABEE (to Mabee Patents Corp.). Can. 286,316, Jan. 8, 1929. Live-stock feed is prepd. by subjecting a mass of moist farm roughage to a conversion reaction in the presence of CaO , MgO , NaCl and S with ready access of air.

Forage. MME. ROSCHERT (née LUCIE ROCH). Fr. 643,236, Oct. 29, 1927. Buckwheat is crushed under high pressure according to the oil-extn. processes, heated to about 70° and pressed into cakes for forage which may be kept indefinitely.

Eccentrically mounted mixing drum for cattle fodder, etc. GEORG WINTERLING. Austrian 111,856. Aug. 15, 1928.

Legitimate technical publicity builds prestige and promotes sales. *Ibid* 26.—This series of articles makes up the first part of a special number of *Chem. Met. Eng.* devoted to the com. side of chem. industry. Supplementing these economic and statistical studies are reviews of advances in technology and of improvements in processes and equipment (pp. 27-37) followed by production and trade statistics relating to various chem. substances (pp. 38-58), special attention being given to N, coal, various acids, S, alkalies, Na phosphate, coal-tar chemicals, potash, Cl, wood-distn. products, NH_3 , fats and oils. F. J. C.

American Society for Testing Materials, Tentative Standards 1928. *Separate* 1928, 932 pp.—Tentative specifications are given for: soft steel track spikes; steel tie plates; iron and steel chain; elec. cast-steel stud-link anchor chain; structural steel for locomotives and cars; marine boiler steel plates; C-steel castings for valves, flanges and fittings for high-temp. service; steel pipes of various kinds for ordinary and high-temp. uses; cold-rolled stripped steel; the arbitration test bar and tension test specimen for cast iron; Zn-coated (galvanized) wire of various kinds; Zn-coated chain-link fence fabric galvanized before and after weaving; Zn (hot-galvanized) coatings on structural steel shapes, plates and bars and their products; fire-refined Cu other than lake; sand castings of the alloy: Cu 80, Sn 10, Pb 10%; brass ingot metal, graded and ungraded, for sand castings; Al-base sand-casting alloys in ingot form; Al-base alloy sand castings; Al ingots for remelting; Al sheet; Ag solders; bronze trolley wire; insulated wire and cable: 30% Hevea rubber; Cu tubing for refrigerators; seamless Cu tubes; rolled Zn; non-ferrous insect screen cloth; compressive strength of portland-cement mortars; sand for use in lime plaster; gypsum molding and pottery plaster; Keene's cement; calcined gypsum for use in the prepn. of dental plasters; concrete aggregates; building brick of various kinds; paving brick; required safe crushing strengths of sewer pipe to carry loads from ditch filling; hollow burned clay fireproofing, partition and furring tile; fire tests of building construction and materials; boiled linseed oil; raw tung oil; soy-bean oil, raw or refined; petroleum spirits (mineral spirits); Ti-Ba pigment; Al powder for paints (Al bronze powder); Au-bronze powder; the toxic ingredients in anti-fouling paints; com. sizes of broken stone, broken slag, sand and gravel for highway construction; broken stone for waterbound base, water-bound macadam surface course, bituminous macadam and bituminous concrete base

and surface; sand for sheet asphalt and bituminous concrete pavements; natural or artificial sand-clay mixts. for road surfacing; CaCl_2 for dust prevention; asphalt cement of various amts. of penetration for use in asphalt block, in sheet asphalt, in various kinds of pavements, and for use as filler for brick and block pavements; tar (high- and low-C) for surface treatment, cold and hot application; tar cement (high- and low-C) for use cold in repair work (cut-block product); tar cement (high- and low-C); coal-tar pitch for stone block filler; asphalt filler for brick pavements (blown type); mineral filler for sheet asphalt and bituminous concrete pavements; wooden boxes, nailed and lock-corner construction and those used for shipment of canned foods; canned foods boxes, wirebound construction; 4-one boxes and similar type boxes; acid-resisting asphalt mastic; rubber insulating tape; cotton rubber-lined fire hose for public and private fire department use; steam hose; tolerances and test methods for rayon, asbestos yarn, knit goods, certain light and medium cotton fabrics; specifications and tolerances for 23/5/3 carded American tire cord; Cuban (jute) raw-sugar bags; thermometers for Engler viscometers. *Tentative methods* are given of: sampling rolled and forged steel products for check analysis; testing Zn-coated (galvanized) iron and steel wire and wire products; tension and compression testing of metallic materials; test for resistivity and for change of resistance with temp. of metallic materials for elec. heating; chem. analysis of Al and light Al alloys, of metallic materials for elec. heating; tests for compressive strength of portland-cement mortars; chem. analysis of limestone, quicklime and hydrated lime; test for field detn. of approx. apparent sp. gr. of fine aggregate, of approx. % of voids in fine aggregate, and of surface moisture in fine aggregate; testing brick (compression, flexure and absorption); test for resistance of fire-clay brick to thermal spalling action; tests for hollow-burned clay fire-proofing, partition and furring tile; testing elec. porcelain; tests for coarse particles in dry pigments and coarse particles and skins in mixts. of pigments and vehicles, for alky. or acidity of pigments, for bleeding of pigments, for hygroscopic moisture (and other matter volatile under the test conditions) in pigments, for oil absorption of pigments, for mass color and tinting strength of pigments; testing shellac varnish; sampling and testing lacquer solvents and diluents; routine analysis of white linseed-oil paints, of dry Cu_2O and of dry Hg_2O ; test for detn. of toluene-insol. matter in rosin (chiefly sand, chips, dirt and bark); sampling petroleum and petroleum products; tests for color of lubricating oils and of petrolatum by means of Union colorimeter, for color of refined petroleum oil by means of Saybolt chromometer, for detection of free S and corrosive S compds. in gasoline, for detn. of autogenous ignition temps., for distn. of crude petroleum, for gravity of petroleum and petroleum products by means of hydrometer, for m. p. of petrolatum, for neutralization no. of petroleum products and lubricants, for penetration of greases and petrolatum, for pptn. no. of lubricating oils, for S in naphthas and illuminating oils; tests for abrasion of gravel, for quantity of clay in sand-clay, topsoil and semi-gravel for highway construction, for the detn. of moisture equiv. of subgrade soils in the field, for consistency of portland-cement concrete, for distn. of bituminous materials suitable for road treatment, for ductility of bituminous materials, for residue of specified penetration, testing bituminous emulsions; test for fineness of powd. coal; detn. of S in coal and coke by the bomb-washing and Na_2O_2 fusion methods; tests for cu. ft. wt. of crushed bituminous coal and of coke; test for sieve analysis of coke; tumbler test for coke; analysis of roofing felt for fiber compn.; test for water absorption of slate; flexure testing of slate (detn. of modulus of rupture and of elasticity); test for detg. the insulating qualities of slate; testing insulating varnishes, sheet and tape insulating materials for dielec. strength, elec. insulating materials for power factor and dielec. const. at frequencies of 100 to 1500 kilocycles, cable splicing and pothead compds., untreated insulating paper, laminated sheet insulating materials, insulating materials for resistance to impact, and varnished cloth tapes; test for surface and vol. resistivity of solid insulating materials; chem. analysis of rubber products; tests for Cuban (jute) raw-sugar bags; testing cotton fibers; testing grease wool and allied fibers for scoured content, identification of textile fibers and their detn. in mixed goods. *Tentative recommended practice* is given for: radiographic testing of metal castings; bituminous paving plant inspection; thermal analysis of steel. *Tentative definitions* are given of: terms relating to heat-treatment operations (especially as related to ferrous alloys); terms relating to the gypsum industry; the term aggregate; the term screen (sieve); terms relating to refractories; terms relating to petroleum; terms relating to coal and coke; terms relating to textile materials; terms relating to methods of testing. *Tentative rules* are given for: inspection of concrete and reinforced concrete work. *Tentative revisions of A. S. T. M. Standards* are proposed for: specifications for steel track spikes; structural steel for bridges and for buildings, structural Ni and Si steel, billet-steel

concrete reinforcement bars, iron and steel chain, staybolt, engine-bolt and extra-refined wrought-Fe bars, gray-Fe and high-test gray-Fe castings, cast-Fe soil pipe and fittings; bronze bearing metal in ingot form, cartridge brass, cartridge brass disks, free-cutting brass rod for use in screw machines, naval brass rods for structural purposes, seamless admiralty condenser tubes and ferrule stock; portland cement, hydrated lime for structural purposes, paving brick, cement-concrete sewer pipe, hollow burned-clay load-bearing wall tile and hollow-burned clay floor tile; broken slag for water-bound base and wearing course, shovel-run or crusher-run broken slag for waterbound base, rubber pump valves; standard methods of chem. analysis of plain C steel; standard methods of chem. analysis of Mn bronze; standard methods of test for coarse particles in paint pigments, routine analysis of Ti pigments, testing shellac, lab. sampling and analysis of coal and coke, testing molded insulating materials, testing rubber products; standard definitions of terms relating to the gypsum industry, the term sand, terms relating to refractories, to paint specifications, to textile materials.

E. J. C.

American Society for Testing Materials, 1928 Supplement to Book of A. S. T. M. Standards. *Separate* 1928, 105 pp.—*Standard specifications* are given for: C-steel and alloy-steel forgings; C-steel forgings for locomotives; forged or rolled steel pipe flanges for high-temp. service; alloy tool steel; Al-bronze castings; sand castings of the alloy: Cu 88, Sn 8, Zn 4%; steam or valve bronze sand castings; yellow brass sand castings for general purposes; bronze castings in the rough for locomotive wearing parts; car and tender journal bearings, lined; brazing solder; clay fire brick for malleable furnaces with removable bungs and for annealing ovens, for stationary boiler service, for marine boiler service; raw linseed oil, Prussian blue, ultramarine blue, chrome oxide green, com. para red, friction tape for general use for elec. purposes. *Standard methods* are given of: test for magnetic properties of Fe and steel; test for softening point of fireclay brick; test for detn. of wax in shellac ("machine-made" and dry-bleached refined shellac); testing oleo resinous varnishes; routine analysis of dry red lead; tests for C residue of petroleum products (Conradson C residue), for cloud and pour points of petroleum products, for sapon. no., for steam emulsion of lubricating oils for water in petroleum products and other bituminous materials, for water and sediment in petroleum products by means of centrifuge; testing gas oils (gr., distn., S, C residue, pour point, viscosity, water); decantation test for sand and other fine aggregates; test for distn. of creosote oil; test for steam distn. of bituminous protective coatings. *Standard definitions* are given of: terms relating to the gypsum industry; terms relating to lime; the term sand; clay refractories; terms relating to refractories.

E. J. C.

Progress in steam research. Report on progress in steam research at the Massachusetts Institute of Technology. FREDERICK G. KEYES AND LEIGHTON B. SMITH. *Mech. Eng.* 51, 123-5(1929). Report on progress in steam research at the Bureau of Standards, with determinations of the heat capacity of water between 0° and 270°. N. S. OSBORNE, H. F. STIMSON AND E. F. FLOCK. *Ibid* 125-7. Experiments on the properties of steam at high pressures. JAROSLAV HAVLÍČEK. *Ibid* 127-8. The new critical-pressure tables compared with recent experiments. J. H. KEENAN. *Ibid* 129. A general steam equation. R. C. H. HECK. *Rutgers Coll. Mech. Eng.* 51, 116-22(1929). E. H.

Calculation of heating surface and steam consumption for heating liquids in open wood vats. HACK. *Chem.-Ztg.* 51, 545-6(1927).—H. discusses heat losses in chemical plants, and gives an example showing the heating surface, steam consumption and saving of money for different conditions of open-tank heating. Twenty percent is added to heat needed for the process to allow for radiation and evapn. M. C. R.

The foundations of the theory of the strength of materials. MAX ENSSLIN. *Z. Ver. deut. Ing.* 72, 1625-35(1928).—Objection is made to the use of the *elastic deformation* in the specifications of metals, because different specimens from the same metal may give widely different values, and as instruments are improved lower and lower values are obtained. The *upper stretch limit* is labile and depends upon accidental peculiarities of the material but the *lower stretch limit* reached after some time is a measurable quantity. The stress-strain curves show the temporary, i. e., elastic, deformation and the lower stretch curve gives a valuable measure of the plastic condition of the metal. Neither of these tests depends on the accidental character of the specimen. The finer the internal structure of the metal the greater the elastic deformation, and the coarser the structure the greater the permanent deformation of plastic flow. In specimens with a fine internal structure the stretch limit often occurs

sharply and at the same load both under tension and compression. The change of orientation during plastic flow explains the difference between the upper and lower stretch limits. The lower stretch limit is a natural const. indicative of the magnitude and internal constitution of the grains. By recrystn. the stretch limit may be made almost completely to disappear. The relation of the tension and twist stretch limit is considered at length. The use of fatigue tests is advocated since failure hardly ever takes place under a dead load.

EUGENE C. BINGHAM

The drying of solids. I. T. K. SHERWOOD. Mass. Inst. Technology. *Ind. Eng. Chem.* 21, 12-6(1929).—The outstanding problems in the drying of solid materials are the questions as to exactly how the water travels through the solid up to the surface, how and where evapn. actually takes place, and how these factors influence the moisture distribution through the solid, the temp. of the material and the rate of evapn. under different conditions of the drying air as to temp., humidity and velocity. The mechanism of the drying process may be divided into those cases where the resistance to internal diffusion is small or great as compared to the resistance to the removal of the vapor. Four general cases result: (1) Evapn. at the solid surface; the resistance to internal diffusion of the liquid is small as compared with the resistance to removal of vapor from the surface. (2) Evapn. at the solid surface; the resistance to internal diffusion of the liquid is great as compared with the resistance to removal of vapor from the surface. (3) Evapn. in the interior of the solid; the resistance to the internal diffusion of the liquid is small as compared with the total resistance to the removal of vapor. (4) Evapn. in the interior of the solid; the resistance to the internal diffusion of the liquid is great as compared with the total resistance to the removal of vapor. Several of these cases may occur in drying of the same material. When the solid is wet enough to dry initially at a const. rate, the drying process may be divided into the const.-rate and falling-rate periods; this paper deals with the falling-rate period, particularly with case 2. The case of drying by internal diffusion of liquid to the surface, with negligible resistance to the removal of vapor, can be covered by equations similar to these of Fourier applying to heat conduction in solids; the drying of solid slabs is a case in point, and a method is described whereby the equations may be used in the analysis of drying data without tedious calcn. or intimate knowledge of the mathematics involved. The theoretical drying equation fits well the data for cases of the drying of wood and clay, and approximates the results in the drying of soap. The diffusion const. of H_2O in soap changes with moisture content of the soap, explaining the deviation of the actual from the theoretical curve. Data obtained on moisture gradients in soap during drying illustrate the same point. W. C. E.

Boiler flue gases are converted into dry ice. G. GROW. *Power* 69, 279(1929).—A popular account of the manuf. of solid CO_2 for refrigeration.

D. B. DILL

Coefficients of flow in concrete pipe. FRID C. SCOBEE. U. S. Dept. Agr., Berkeley, Calif. *J. Am. Water Works Assoc.* 21, 1-30(1929).

E. J. C.

Breathing apparatus and its utility. C. H. BURWOOD. *Munic. Eng. Sanit. Record* 81, 586(1928).—A discussion is given of self-contained O-breathing app. for fire-fighting, etc.

C. H. BADGER

Explosive limits of gases to be observed in factories (WEISSENBERGER, PIATTI) 24.
How volatile solvents behave (SMITH) 24. Research within an industry creates the demand - and supplies it (PARTRIDGE) 9.

Purification of gas. FRANZ FISCHER. Fr. 642,892, Oct. 22, 1927. See Brit. 282,601 (*Ch. A.* 22, 3715).

Purification of gases. THE KOPPERS CO. Ger. 469,316, Nov. 3, 1922. The app. comprises a tower with divisions for the absorption of the gas by a liquid and the regeneration of the liquid by aeration.

Separating gases and vapors. I. G. FARBENIND. A.-G. Brit. 292,204, Dec. 10, 1926. In effecting sepn. or drying of gases, 2 or more adsorbents of different structure are used successively, one at least of which is of hydrophile character. Preferably the mixt. is first brought into contact with a "wide-porous" adsorbent and then with a "fine-porous" adsorbent. The process may be applied to a variety of sepn., among which are mentioned purification of HCl contaminated with hydrocarbons (as obtained in chlorination processes), removal of water vapor or CO_2 from gases which are to be liquefied as in the Linde process, drying of O or other gases which are to be compressed in cylinders, and adsorption of H_2S from illuminating gas or water gas contg. air and NH_3 . Numerous details and modifications are given.

Extracting foreign substances from gases. JAMES GORDON & Co., LTD. Fr.

642,849, Oct. 8, 1927. Foreign substances are extd. from gases centrifugally and are carried away by a thin liquid film moving constantly along a collecting surface in the direction of flow of the gases.

Separating microorganisms or other particles from air or other gases or vapors. PLATEN-MUNTERS REFRIGERATING SYSTEM AKTIEBOLAG. Brit. 292,479, June 18, 1927. The air or other gas is caused to pass through or over a filter carrying resin, wax, rubber, shellac or the like which has been melted and allowed to solidify in a strong elec. field.

Separating air from liquids. UETTWILLER & CIE (S.À.R.L.). Fr. 643,119, Oct. 17, 1927. Air is sepd., particularly from transformer oil, by passing the oil from an exterior vessel in which the speed is diminished to an interior vessel in which the speed is again increased, a filter being placed between the 2 vessels.

Washing gases. I. G. FARBENIND. A.-G. Brit. 293,003, June 29, 1927. A small proportion (suitably about 0.1–0.2%) of a wetting agent such as is employed in the textile industry (suitably a sulfonic acid or salt of suitable character) is added to a gas-washing liquor in order to retain dust. An org. solvent such as tetrachloroethylene may also be added in small proportion to prevent the formation of froth.

Gas reactions. I. G. FARBENIND. A.-G. Fr. 643,127, Oct. 19, 1927. In gas reactions under the influence of mild elec. discharges, the condensation of the products of reaction on the walls of the chamber is reduced or prevented, whereby the process is greatly improved. An example is given of the production of H_2O_2 from H and O, in which the cooling water is kept at 80°. The yield per hour is increased from 2.5 to 4 g. with 10% less energy.

Sterilizing liquids. GEORG A. KRAUSE. Fr. 643,610, Oct. 13, 1927. Water or other liquids are sterilized by being brought into contact with, or into bodies of regular or different shapes, composed of, or covered with metals such as Cu or Ag, or alloys capable of destroying microorganisms. The bodies are arranged to divide up the liquid and to give a large contact area. The treatment may be preceded or followed by filtration, which may be in a filter contg. the metals, and in the treatment itself the bodies may be disposed to give a filtering effect.

Fractional distillation. THERMAL INDUSTRIAL & CHEMICAL, T. I. C., RESEARCH CO., LTD., and WM. J. CHADDER. Fr. 643,451, Nov. 7, 1927. See Brit. 269,090 (Cl. 22, 1463).

Separating products of different density by washing. ARMAND JACQUELIN. Fr. 643,486, Apr. 1, 1927.

Separation of solids from liquids. RESIDUUM SEPARATIONS CORP. Fr. 643,693, Nov. 9, 1927. Solids such as asphalt and carbonized materials are sepd. from liquids, such as crude gasoline, by projecting the liquid on to grinding balls in a rotating cylinder whereby the solids are pulverized and the liquids vaporized.

Separating solids from liquids by a thickening and clarifying process. ALFRED L. BLOMFIELD, LOYAL S. HARNER and HARRISON S. COE (to Cycle Co.). U. S. 1,702,192, Feb. 12. Mech. features. U. S. 1,702,193 also relates to app. for the same purpose.

Washing coal or other solid materials. M. JUNG. Brit. 292,487, June 17, 1927. Liquor is sepd. from the products obtained in washing coal or other materials by "dynamic action" or by the action of gas under pressure or of a vacuum or by centrifugal action or by vibration. An app. for treating coal and sepg. dry products is illustrated.

Fractionation system for separating coal-tar oil constituents or other liquids of different boiling points. BATES TORREY, JR., and GEORGE R. SANFORD (to Smet Solvay Co.). U. S. 1,701,988, Feb. 12.

Recovery of dissolved or suspended substances. WM. BARRS and EDWARD BARRS. Fr. 643,102, Oct. 5, 1927. Suspended or dissolved substances such as *caustic alkalis* in the "black liquor" from paper manuf. are recovered by submitting the liquor directly in a scrubber to the action of a gaseous evapg. agent, such as flue gases coming from incineration operations of the process. A suitable app. is described.

Recovery of volatile products. CARBIDE AND CARBON CHEMICALS CORP. Fr. 643,322, Nov. 3, 1927. See Brit. 291,277 (Cl. A. 23, 1188).

Recovery of volatile solvents. FERDINAND JEAN. Fr. 643,501, Apr. 5, 1927. Volatile solvents used for extn. are recovered by distn. under vacuum, and the vapors obtained are submitted to a thermocompression by addn. of steam at a pressure above atm., and condensing the vapors thus compressed at a temp. higher than that at which they were distd. under vacuum.

Treating gasoline or like volatile oils to prevent evaporation losses. RUDOLPH CONRADER. U. S. 1,701,870, Feb. 12. Oil in a closed receptacle is subjected to the action of a gas which is delivered to and drawn off from the receptacle to maintain

the oil under superatm. pressure, liquid is condensed from the gas removed and the liquid is returned to the receptacle. An app. is described which is suitable for storage of gasoline.

Removing solvent from plastic, gummy or amorphous materials such as styrene. W. S. JOHNSTON and A. W. KEEN (to Naugatuck Chemical Co.). Brit. 292,137, June 15, 1927. See U. S. 1,673,685 (C. A. 22, 2801).

Washing benzene, alcohol, etc. SOCIÉTÉ D'EXPLOITATION D'USINES MÉTALLURGIQUES. Fr. 643,500, Apr. 5, 1927. Benzene, alc., gasoline or oils are treated with denser liquids for washing or chem. treatment in air-tight containers, a current of the lighter liquid ascending against a current of descending heavier liquid, the container being filled with Raschig rings or the like.

Wetting and dispersing agents. BADISCHE ANILIN- & SODA-FABRIK. Fr. 33,246, Mar. 15, 1927. Addn. to 601,823. Sulfonated mineral oils, distn. products of naphtha, tar oils or their Na salts are used for dyeing, milling, bleaching, etc., baths or for transforming org. compds. into a finely divided state.

Determination of the temperature of high-speed bodies such as the rollers of rubber-making machines. SIEMENS-SCHUCKERTWERKE A.-G. and ACCUMULATEUR-FABRIK A.-G. Ger. 470,201, May 10, 1923. A substance is employed which turns suddenly from the opaque to the transparent state at a known temp., thus permitting a colored background to become visible.

Granulating raw cement materials or other powdered substances. O. LELLEP. Brit. 292,987, April 2, 1927. Drops of water are added to the material while it is in motion, as on a rotary drum. An app. is described.

Dehydrating oils, fats, etc. CHARLES V. ZOUL (to Celite Co.). U. S. 1,701,092, Feb. 5. The material to be dehydrated, in liquid condition, is brought into contact with an adsorbent such as diatomaceous earth which is commingled with a substance such as calcined gypsum capable of taking up water from the liquid to be dehydrated to form a hydrate contg. H_2O of crystn.

Drying. WALTER A. DETER. Ger. 470,214, Feb. 1, 1925. Water-contg. raw material is dried between rapidly rotating members provided with small brushes.

Colloidal dispersions. P. G. M. A. PIGACHE. Brit. 292,965, June 27, 1927. See Fr. 639,069 (C. A. 23, 655).

Making colloidal dispersions, etc., by grinding with porcelain balls or the like. P. KLEIN (to Anode Rubber Co., Ltd.) Brit. 293,071, March 1, 1927. An app. is described.

Emulsifying agents and emulsions. I. G. FARBENIND. A.-G. Fr. 33,278, Mar. 25, 1927. Addn. to 608,302. Emulsions of oils, fats, hydrocarbons, etc., for lubricating in spinning are prep'd. by the addn. of alkylated cellulose and sulfonic acids of aromatic compds. or hydrogenated aromatic compds. contg. alkyl, aryl, aralkyl or cycloalkyl groups or their Na salts. If the emulsifying agents are mixed with glue, gelatin, etc., they may be used for the *prepn. of pigments* or for the *treatment of wool, cotton, leather*, etc.

Electric resistance material. JUAN FIDALGO, FRANKLIN ORIVE and FRANCISCO SANSO. U. S. 1,701,916, Feb. 12. A resistance suitable for use with radio receivers comprises a mixt. of "smoke black," "vegetal coal" and sugar sirup surrounded by a linen covering.

Refrigerating system. SETH L. BRIGHT (to G. F. Lathrop and John J. Dodge). U. S. 1,700,429, Jan. 29. A refrigerant such as CO_2 is discharged into a brine soln. to freeze the latter and the discharge is controlled by the change in volume which occurs on freezing of the brine. An app. is described. U. S. 1,700,430 specifies an app. in which different cooling media such as water and chilled brine are successively admitted into a container for cooling in 2 stages.

Refrigerating system with a vaporized propellant for circulating the refrigerant. COMSTOCK & WESCOTT, INC., L. F. WHITNEY and E. A. WEAVER. Brit. 292,812, Sept. 22, 1927.

Refrigerating system suitable for use with ammonia. SILLER & RODENKIRCHEN GES. and W. SILLER. Brit. 292,402, Oct. 15, 1927.

Refrigerating system of the compression type. SIDNEY E. WILSON. U. S. 1,702,445, Feb. 12.

Refrigerating apparatus of the compression type. JUSTUS C. GOOSMANN. U. S. 1,701,753, Feb. 12.

Refrigerating apparatus of the compression type (suitable for use with sulfur dioxide). SOCIETÀ ANON. ITALIANA NORD FRIGOR. Brit. 292,482, June 18, 1927. Structural features.

Refrigerating system of the absorption type. E. B. MILLER (to Silica Gel Corp.). Brit. 292,938, June 27, 1927. In an app. suitable for use with brine or SO_2 and silica gel, adsorber units are employed, which successively undergo adsorption, preliminary heating, heating for activation and cooling preparatory to further adsorption, and the heat is transferred from one unit to the next by a fluid such as air, which is forced or drawn through the app.

Refrigerating system of the absorption type. S. K. D. M. VAN LIER. Brit. 292,326, May 18, 1927.

Refrigerating apparatus of the absorption type. D. F. KEITH. Brit. 292,944, June 27, 1927. A portable valveless app. is described which operates on the reversing system.

Refrigerating apparatus of the absorption type. EDMUND ALTENKIRCH (to Siemens Schuckertwerke A.-G.). U. S. 1,700,276, Jan. 29.

Refrigerating apparatus of the absorption type. ELECTROLUX, LTD., and R. J. CRACKNELL. Brit. 292,199, Feb. 18, 1927.

Refrigerating system of the continuous-cycle absorption type. SIEMENS-SCHUCKERTWERKE A.-G. Brit. 292,556, June 22, 1927. A thermostatic regulation device is described.

Refrigerating system of the continuous-cycle absorption type. PLATEN-MUNTERS REFRIGERATING SYSTEM AKTIEBOLAG (to Electrolux, Ltd.). Brit. 292,480, June 16, 1927. Structural features.

Refrigerating apparatus of the reversing absorption type. C. POHLMANN. Brit. 292,568, June 23, 1927. Structural features.

Condenser for refrigerating apparatus. FOREST O. RIEK. U. S. 1,702,020, Feb. 12.

Evaporators for electric refrigerating machines. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 643,417, Nov. 7, 1927.

Float-valve device for controlling the supply of refrigerant in refrigerating apparatus. CHRISTIAN STEENSTRUP (to General Electric Co.). U. S. 1,701,343, Feb. 5.

Refrigerator. SULZER FRÈRES, SOCIÉTÉ ANON. Fr. 643,667, Nov. 8, 1927.

Insulating material. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 643,415, Nov. 7, 1927. The elements of an insulating material are agglutinated by a "degelled" oil, *i. e.*, a drying or semi-drying oil heated first to the state of a "gel," then brought to the liquid state.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

An unpurified pure water. F. T. UNDERHILL. *Pub. Health J.* (Canadian) 19, 463-5(1928).—Brief details are given of the water supply of the Greater Vancouver Water District, which is derived from two mountain streams, Capilano River and Seymour Creek, and distributed by gravity without any form of treatment. Logging operations in that portion of the watershed which is not owned by the District or situated in the forest reserve are strictly supervised. Every individual must show a negative Widal test before being admitted to the watershed, and fishing and hunting are prohibited. The av. compn. of the Capilano and Seymour waters, resp., during 1927, was as follows, in p. p. m.: total solids 37.20 and 45.35, chlorides 2.69 and 2.73, free NH_3 0.017 and 0.025, albuminoid NH_3 0.027 and 0.032, N as N_2O_5 0.58 and 0.62, N as N_2O_3 nil; reaction neutral. The av. bacterial counts were 21 and 40 per cc., resp. R. E. T.

Water-purification progress during the year 1928. NORMAN J. HOWARD. Filtration Plant Laboratories, Toronto, Ont. *Contract Record and Eng. Rev.* 42, 1355-61(1928).—An extensive review and discussion. R. E. THOMPSON

The new water-works system of the Greenwich Water Company. DANA M. WOOD. *J. New England Water Works Assoc.* 42, 378-95(1928).

The new purification plant of the Greenwich Water Company. E. SHERMAN CHASE. *J. New England Water Works Assoc.* 42, 396-409(1928).—The water from 2 large drainage reservoirs goes through filters either to aerators or to chem. mixing tanks. Ordinary filter alum and, later, soda ash are added. The settling basins allow a theoretical detention period of 4 hrs. Chlorination follows. The use of soda ash in excess has reduced the corrosive qualities of the supply. D. K. FRENCH

The Montreal Filtration Works. FREDERICK E. FIELD AND JOHN H. HARRINGTON. *J. New England Water Works Assoc.* 42, 359-71(1928).—Works designed for double

filtration without using coagulants, the plant design permits operation of either pre- or final filters as a unit plant. The water is chlorinated afterward. D. K. F.

Recent developments in water purification. WELLINGTON DONALDSON. *J. New England Water Works Assoc.* 42, 372-7(1928).—The discussion is confined to certain improvements and refinements in the more important phases. Clarifying, mixing and filtering practice on the phys. side, and aeration, softening and chlorination on the chem. side are touched on. D. K. FRENCH

Filter and pump layout for Jackson water works. J. H. FERRELL. *Eng. News-Record* 101, 552(1928).—A brief illustrated description of the new plant at Jackson, Miss., treating Pearl River water, which consists of a 7-million gal. raw-water reservoir, mixing flumes, coagulation basins, ten 1-million gal. per day rapid sand filters and a 1-million gal. clear-water reservoir. The chem. machines are of the dry-feed type. The pumping plant consists of electrically driven centrifugal pumps with steam-driven units for stand-by purposes. R. E. THOMPSON

Latest methods for the complete purification and total demineralization of hard waters. A. The zero hydrotitrimetric scale compared with partial purification methods. L. J. SUPERBIE. *Science et Ind.* 12, No. 175, 88-93(1928).—The use of the hydrotitrimetric scale enables the lab. or field worker to grade accurately a water as regards its hardness. Zero on the scale corresponds to entire absence of Ca or Mg salts. The use of pptn. and base-exchange methods is discussed with reactions and lies. Pptn. methods always leave residual hardness in water, which is best removed by base exchange. Soft water is necessary for laundry, textile and various industries. One division on the hydrotitrimetric scale means the consumption of approx. 110 g. of soap per cu. m. of water. Complete softening of industrial waters may be carried out efficiently at a relatively low cost. B. Softening apparatus for domestic use. PIERRE QUIQUANDON. *Ibid* 93-6. —Home water-softening methods and equipment are described with illustrations. C. The demineralization of water without distillation. R. MARIE. *Ibid* 96-9. —Good results were obtained by the combined use of soda lime and base exchange. A water contg. 110 mg. per l. of CaO and 18 mg. per l. of MgO with a hydrotitrimetric titer of 23° was reduced by the treatment to a titer of 0 and with entire absence of CaO and MgO. The ash content was increased from 82 g. per l. to 155 by the process. An electroosmotic app. for demineralization is described. Such an app. on a com. scale is relatively inexpensive and removes a substantial part of the dissolved salts. Where complete demineralization is unnecessary, as in drinking water, the method may be of use. A com. installation is described with approx. cost data. C. R. FELLERS

Chlorination in the field of sanitation. I. Developments in water purification. L. H. ENSLOW. *Compressed Gas Manufs. Assoc.* 1929; (preprint); C. A. 23, 1192.

J. A. KENNEDY

The effect of sunlight on the determination of chlorine by the *o*-tolidine method. F. R. MCCRUMB AND W. R. KENNY. *J. New England Water Works Assoc.* 42, 410-3 (1928).—While direct sunlight does not interfere with color formation, it causes it to fade, thus producing low results. Samples should not be exposed to sunlight in clear glass bottles, as reduction in Cl concn. follows. D. K. FRENCH

The electrical conductivity and refractive index of water from peat marshes. I. A. SMORODINTZEV AND A. N. ADOVA. *J. Russ. Phys.-Chem. Soc.* 60, 497-505(1928).—The cond. varied with the mineral content of the sample while the n was largely detd. by the org. matter. Samples obtained from carex marshes conducted 4-5 times better than those from sphagnum marshes, the latter being characterized by a higher n . B. SOVENKOFF

Further instances of use of artificial turbidity for algae control. LEWIS V. CARPENTER. *Eng. News-Record* 101, 852(1928); cf. C. A. 22, 4682.—Two instances are cited of the use of added turbidity for algae removal. During the summer of 1924 trouble was experienced at Huntington, W. Va., with the filters becoming clogged by *Synedra*. Copper sulfate and prechlorination killed the organisms but they remained in suspension. Addn. of sufficient clay to increase the turbidity from 8-10 to 50-75 p. p. m. aided settling out of the dead organisms and materially increased the length of the filter runs. During the summer of 1925 dry clay was added to the raw water at Evanston, Ill., through a dry-feed machine, as an aid to algae removal. R. E. THOMPSON

Prevention of pollution in the Upper Tame Basin (England). F. L. WARDMAN. *Munic. Eng. Sanit. Record* 82, 10-1(1928).—Discussion. C. H. BADGER

Growing pains. (Municipal work at Hinckley, England.) J. S. FEATHERSTON. *Munic. Eng. Sanit. Record* 81, 575(1928).—A discussion of the highways is given.

Gas production in the p_H 6.4 sludge was as rapid during the first 15-20 days as from the other samples, but gasification from then on was slight. This indicates that the completion of the process depends on organisms which function only at a higher p_H value. Practically no gasification occurred in the sample maintained at p_H 8.4, and there was little evidence of biol. activity. At the end of 163 days the control had a p_H value of 5.0 and contained 61.3% volatile material. The samples maintained near neutrality had no objectionable odor at the end of 35 days and water sepd. readily. The sludges maintained at p_H 6.4, 8.0 and 8.4 had objectionable odors and did not sep. from the water as rapidly. The CH_4 generated in the p_H 6.8-7.6 samples was approx. 450 cc. per g. of fresh volatile solids in 30 days. An additional 20 days increases the vol. to approx. 500 cc.

R. E. THOMPSON

Fertilizing value of Baltimore sewage sludge. C. E. KEEFER AND G. K. ARMELING. *Eng. News-Record* 101, 837-40(1928).—Results are given of field expts. carried out over a period of 5 yrs. The sludge employed consisted of that removed from the primary and final settling tanks of the Baltimore sewage works and digested in sep. tanks. Expts. were made with wet and air-dried sludge, 40 and 20 tons, resp., being applied per acre. The latter, dried on sand beds and consequently contg. 56% of sand, had a moisture content of 65-70% and analyzed as follows (dry basis): N as NH_3 2.2%; total H_3PO_4 as P_2O_5 0.5%; K as K_2O 0.2%; fats 9.8%. Six crops were planted—potatoes, spinach, string beans, tomatoes, corn and cabbage—and comparisons were made with other fertilizers. Application of sludge to the land increased the yield of all the crops, potatoes, cabbage and corn thriving the most and spinach and tomatoes responding the least. The results indicated that the sludge continued to give plant food to the soil the second year after application.

R. E. THOMPSON

Settling tanks lighten burden on Tucson sewage farm. F. M. VEATCH. *Eng. News-Record* 101, 768-70(1928).—Settling tanks, sludge-digestion tanks and sludge-drying beds have been constructed at Tucson, Ariz., to facilitate operation of the 750-acre sewage farm and to reduce odor nuisance. A study of the farm indicated that the odors were due to sludge deposits in poorly maintained irrigation ditches, unburied screenings and improperly prepd. fields, which allowed ponding of the sewage. The 2 settling tanks are equipped with Dorr revolving scrapers and will provide a total retention period of 20 mins., which is believed to be sufficient for removal of the grosser solids. The digestion tank capacity provided is equiv. to 2 cu. ft. per capita, and the drying beds, which consist of 6 in. of sand on 9-15 in. of gravel, underdrained, have capacity equiv. to $\frac{1}{3}$ sq. ft. per capita. Because of the low flow of the Santa Cruz River into which the effluent is discharged, the settling tanks were designed as the preliminary part of an activated-sludge plant which may later be found necessary. The present population is 32,500.

R. E. THOMPSON

Present-day sanitary practice. A. W. GOOD. *Munic. Eng. Sanit. Record* 82, 78(1928).—Certain recommendations for better administration are made

C. H. BADGER

Application of reinforced concrete to public health work. H. J. DEANE. *Munic. Eng. Sanit. Record* 82, 78(1928).—General discussion.

C. H. BADGER

Municipal work at Hartlepool (England). J. H. MIERS. *Munic. Eng. Sanit. Record* 81, 632(1928).—Recreational and other public improvements such as concrete promenades, walls, etc., were built to protect and improve the town as a seaside resort and to reduce unemployment. Brief statements are made regarding subsidy houses, highways and sewers. The sewage is discharged untreated through 4 outfall sewers to low water mark, although, since some of the low-lying districts are tide-locked, flushing is regularly needed.

C. H. BADGER

Salvage plant for refuse disposal (Crewe, England). H. Y. STAZICKER. *Munic. Eng. Sanit. Record* 82, 78(1928).—The refuse is hand-sorted. Paper and tins are baled. A magnetic separator removes metals. Dust, cinders, etc., are screened. The waste from the picking table, screen and garbage extractor is burned.

C. H. B

Notes on public cleansing work, etc., of Liverpool (England). W. MUIRHEAD. *Munic. Eng. Sanit. Record* 81, 664(1928).—About 1500 men are employed in cleaning Liverpool's 27,678 acres. The 1200 tons of daily refuse is removed by 156 carts and 50 motors. The disposal is as follows: tipping 40.23%; destructors 34.55%; dumped at sea 16.39% and sent to farms by canal and rail 8.83%.

C. H. BADGER

Refuse storage, collection and disposal in the borough of Brighouse (England). C. R. MOSS. *Munic. Eng. Sanit. Record* 82, 52(1928).—The rate, amt. of refuse and cost of the plant are given.

C. H. BADGER

Mixed-refuse incinerator for Borough of Queens. JOSEPH C. WOODMAN. *Eng. News-Record* 101, 845-6(1928).—An illustrated description of the incinerator recently

constructed in the Borough of Queens, New York City. The installation consists of three 90-ton furnaces of the Decarie heavy-duty steel water-jacketed type, embodying the distinctive principle of unrestricted upward combustion of the refuse, the wetter material being dried out in a suspended water-cooled basket grate before dropping to the lower grate where final burning takes place.

R. E. THOMPSON

Gas-works effluent (SMITH) 21. Coefficients of flow in concrete pipe (SCOBEY) 13. Vapor pressures of fumigants. I. Me, Et, iso-Pr and sec. Bu chloroacetates (NELSON) 2. Filters (Fr. pat. 33,291) 1. Filtering material (U. S. pat. 1,702,104) 18.

Purifying water. AKTIEBOLAGET FILTRUM. Brit. 293,033, July 1, 1927. An app. is described suitable for removing Ca, Fe and Mn compds. from water and periodically regenerating the treating material.

Purifying water. HÖGANÄS-BILLESOLMS AKTIEBOLAG and NORDISKE NATROLITH AKTIESELSKABET. Fr. 643,228, Oct. 29, 1927. See Brit. 279,788 (C. A. 22, 3010).

Sterilizing and dechlorinating water. O. ADLER and R. ADLER. Brit. 292,099, June 13, 1927. In dechlorinating water by passing it through or over coarse pieces of carbonaceous material, as described in Brit. 286,338 (C. A. 23, 227), the water is first caused to flow over substances insol. in water, resistant to free Cl and capable of pptg. and retaining salts of Fe, Mn and other heavy metals. MnO_2 , "manganese acid," Fe_2O_3 and alk. earth carbonates may be used, alone or pptd. on other materials such as sand, pumice or tuff. To avoid undesired increase of H-ion concn., substances such as $CaCO_3$ or bauxite may be mixed with the carbonaceous material or used for sep. final treatment of the water.

Treating boiler water. JULIUS OSTERTAG. U. S. 1,700,714, Jan. 29. During normal operation of a boiler, sludge-contg. water is continuously blown off and led to a region of lower pressure while maintaining its heat content to generate steam, the generated steam is condensed, make-up water and remaining blow-off water are passed in sep. streams in heat-exchange with each other, and the condensate is added to the heated make-up water. U. S. 1,700,715 and U. S. 1,700,716 relate to similar processes and all three pats. describe app.

Apparatus for softening water by use of zeolites. WALTER J. HUGHES (to Permutit Co.). U. S. 1,701,719, Feb. 12.

Sheet-metal tanks for containing corrosive liquids such as occur in zeolite water-softening systems. EDWIN A. ROBERTSON (to Permutit Co.). U. S. 1,701,729, Feb. 12.

Activated-sludge treatment of sewage. KARL IMHOFF. U. S. 1,700,722, Jan. 29. Sewage is passed through a preliminary settling tank, thence to an aeration tank, then through a sedimentation and sepn. tank, and activated sludge is returned from the last-mentioned to the first-mentioned tank. U. S. 1,700,723 specifies a method of treating sewage in settling basins contg. contact or adhesion filters; a circulating movement is imparted to the sewage so that it is caused to flow through the adhesion filter in one direction and to flow back in the opposite direction through the free space of the settling basin outside of the filter. An app. is described.

Apparatus for removing scum from sewage in treating systems, etc. HENRY E. ELROD. U. S. 1,700,791, Feb. 5.

Treating garbage. EDWARD H. BRUNE. U. S. 1,700,608, Jan. 29. A mixt. of $FeSO_4$ 1, water 18 and CaO 100 parts is used for deodorizing garbage and prepg. it for use as a food for animals.

Incinerator for garbage, rubbish, etc. HARLAN COE. U. S. 1,700,560, Jan. 29.

15 - SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

The soil solution: Its function in the maintenance of fertility. ALEX. M. SMITH. *Fertilizer, Feeding Stuffs & Farm Supplies J.* 14, 11-2(1929).—This paper discusses briefly the relation between the soil soln. and fertility. K. D. JACOB

The influence of the soil reaction on the ionizable constituents of the tomato as determined by electrodialysis. E. S. HABER. Iowa State College. *J. Agr. Research* 37, 101-14(1928).—More acid materials were found by electrodialysis in plants grown in acid soil and more basic materials in those grown on alk. soil. The roots, stems, leaves and fruit from plants grown on a soil of pH 4.0-4.5 contained 15.19, 11.76, 3.46 and 4.87% less titratable base and 60.14, 21.08, 19.29 and 2.54% more acid, resp.,

than those from plants grown on a neutral soil. When the soil reaction was pH 8.5-9.0, the titratable base ranged from 78.06 to 4.48% more and the acid from 19.56 to 1.73% less, resp., than when the plants were raised on neutral soil. The leaves contained more and the roots less ionizable materials than other parts of the plant. Thirteen references are given.

Superphosphate and soil acidity. C. KRUGEL. *Fertiliser, Feeding Stuffs & Farm Supplies J.* 14, 17-8(1929).—This paper reviews briefly the results of recent expts. which show that superphosphate does not cause soil acidity and is not physiologically acid in its action on plants.

A. L. MEHRING

K. D. JACOB

The weed flora of fields and its significance as a biological reagent for the soil reaction. KARL STEYER AND GEORG EBERLE. *Agr. Expt. Sta., Lübeck. Arb. Biol. Reichsanst. Land-Forstw.* 16, 325-422(1928).—Detns. of reaction were made on H_2O and on KCl-soln. exts. by colorimetric and quinhydrone electrode methods. The reaction values preferred by over 25 individual species of weeds were detd. by tabulating % occurrence at each 0.1 pH unit. It then proved possible to est. the H -ion concn. of a given soil area by observation of the frequency of occurrence of the different weeds. The knawel (*Scleranthus annuus*) proved especially well adapted to such reaction-diagnosis, occurring in abundance only in strongly acid soils ($pH < 5.7$), having a high lime requirement. To the practical agriculturalist this method seems likely to be of more value than the physical-chem. methods which are so open to error in untrained hands.

E. T. WHERRY

A possible relationship between soil salinity and stand in cotton. J. ARTHUR HARRIS. *U. of Minn. J. Agr. Research* 37, 213-31(1928).—Soil salinity was measured in terms of the elec. resistance of the satd. soil in a standard soil bridge cup. Four varieties of cotton were planted in field plots at the rate of 6 seeds per hill. The soil samples were taken from the hills in 1 expt. A significant neg. correlation between soil resistance and seedling stand indicated that under the range of exptl. conditions better germination was obtained on more saline soils. The following year soil samples were taken from the middle of the rows and in this case no correlation was found.

A. L. MEHRING

The influence of chilling, above the freezing point, on certain crop plants. JACQ. P. F. SELLSCHOP AND S. C. SALMON. *Kansas Agr. Expt. Sta. J. Agr. Research* 37, 315-38(1928).—Exposure at 0.05-5.0 for 24 hrs. was fatal to rice, velvet beans and cotton. A no. of other crops showed injury of various kinds, but potatoes, tomatoes, buckwheat, soy beans and flax were uninjured by chilling for 96 hrs. Cowpeas, peanuts, maize and velvet beans were more severely injured by chilling when growing in wet than in dry soil. The presence of $NaNO_3$ in the soil soln. was fatal when some plants were chilled, whereas only moderate injury was obtained without it. On the other hand, the presence of KNO_3 protected them from injury. K ions assisted plants to withstand injury; Ca ions were without effect or slightly injurious and Na ions were decidedly deleterious when the plants were chilled.

A. L. MEHRING

The usefulness of capillary potential to soil moisture and plant investigators. LORENZO A. RICHARDS. *Utah Agr. Expt. Sta. J. Agr. Research* 37, 719-41(1928).—Soil moisture is studied from the standpoint of energy potentials. An app. for measuring capillary potential is described and exptl. data are given which show the relation between this function and the moisture content of 4 soils. The flow of moisture through soil, V , can be expressed in terms of capillary cond., K , and potential gradient, $grad \Phi$, thus: $V = -K grad \Phi$ (1). The potential theory is applied to flow of moisture downward after rainfall, upward from a water table, and horizontally. The availability of soil H_2O to plants depends upon the force with which H_2O is held by the soil and the rate of flow of other H_2O to replace that used by the plant. Capillary potential is a direct measure of the force with which the soil holds moisture and the rate of flow may be quantitatively expressed by use of equation (1). A new form of app. is described, with which soil moisture for potted plants may be controlled.

A. L. M.

The water relations of Yakima Valley soil. CARL S. SCOFIELD AND COULSEN C. WRIGHT. *U. S. Bureau of Plant Industry. J. Agr. Research* 37, 65-85(1928).—The sandy loam used in the expts. had a moisture equiv. of 16%. One in. of H_2O in 1 ft. of this soil = 6% of the dry wt. of the soil. When thoroughly irrigated, it holds 16 in. of H_2O in the first 6 ft., and when a crop has absorbed all the H_2O possible, it still contains about 5 in. in the first 6 ft. When irrigation is needed, probably 10 in. of H_2O still remains in this zone. Application of 4-6 acre-in. of H_2O at each irrigation does not result in leaching. If very dry, it may hold 10 in. of irrigation without leaching. When the soil contains less H_2O than its carrying capacity, loss by vaporization takes place well down in the soil as well as at the surface. Movement of H_2O through the

oil takes place by vaporization and condensation as well as by capillarity. With this soil, the proportion of H_2O available to alfalfa is about 70% of the field-carrying capacity. A. L. MEHRING

Soil bacteria and fertility. P. H. H. GRAY. Rothamsted Expt. Station. *Science Progress* 23, 444-56(1929).—A review. JOSEPH S. HEPBURN

Acetic acid as a soil disinfectant. WM. L. DORAN. Mass. Agr. Expt. Sta. *J. Agr. Research* 36, 269-80(1928).—Applications of $AcOH$ temporarily increased the acidity of the soil, but both in the lab. and in the field the original pH value was restored after a few days or weeks according to the quantity used. Applications of 1% $AcOH$ to the soil at the rate of $1\frac{1}{2}$ gal. per sq. ft. was sufficient to protect seedlings from injury by root rot and damping off. When the acid is prepd. from vinegar, the cost of disinfection was about one-half that when formaldehyde was used. $AcOH$ is toxic to plants and must therefore be used a week or two in advance of planting. Twenty-seven references are given. A. L. MEHRING

Quantities of fertilizers used in the year 1927, and their distribution over the area lanted (Java). W. J. HEYLIERS. *Arch. Suikerind.* 36, III; *Mededeel. Proefsta. Java Suikerind.* 917-47(1928); cf. *C. A.* 21, 3414.—Statistical tables show the amts. of each fertilizer material for each plantation, total as well as per unit of area, for all the 178 factories. The relative importance of different fertilizers was about the same as that in the previous year. P. R. PEKELHARING

Present-day tendencies in the fertilizing of grassland. G. A. COWIE. *Fertiliser, Feeding Stuffs and Farm Supplies J.* 14, 39-42(1929).—This paper discusses the results of expts. in Great Britain on the use of fertilizers on pastures and grasslands. In general, ground North African phosphate rock has given practically as good results as basic slag, the availability of phosphate rock increasing with the fineness to which it is ground. K. D. JACOB

Physiological culture. N. A. BARBIERI. *Atti accad. Lincei* 7, 1043-50(1928).—A review of fertilizers and their action and effects in improving plant growth. A. W. CONTIERI

The yields of digestible nutrients and of starch value from two and three mowings and under different fertilizer treatments. SIEGFRIED HIRSCH. *Z. Tierzücht. Züchtungsbiol.* 11, 409-31(1928).—Mowing meadow grass twice during the season resulted in a greater total yield of green material, dry matter, digestible org. matter and starch value than mowing three times. The hay obtained by the more frequent mowing was richer in digestible crude protein, and poorer in crude fiber. The trials were carried out on both fertilized and unfertilized soils. L. A. MAYNARD

Further tests of poison baits in South Wales. H. W. THOMPSON. Univ. Coll., Cardiff. *Welsh J. Agr.* 4, 342-7(1928).— $CuSO_4$ was not an effective bait poison for leatherjackets and slugs. Derris powder gave moderately good results, while Na_2SiO_3 was almost as effective as Paris green. K. D. JACOB

Some experiments for the control of mangold fly. C. L. WALTON. Univ. Coll., Bangor. *Welsh J. Agr.* 4, 347-50(1928).—Green tar oil, nicotine sulfate dusts and Bordeaux sprays did not control the mangold fly (*Pegomyia betae*) on sugar beets and mangolds. Good results were obtained with either paraffin emulsion or nicotine sulfate sprays applied as soon as the plants were through the soil. K. D. JACOB

Seed treatment as a means of preventing turnip flea beetle attack. J. R. W. JENKINS. Univ. Coll., Aberystwyth. *Welsh J. Agr.* 4, 334-42(1928).—Good control of the turnip flea beetle was obtained by thoroughly wetting the turnip seed with turpentine or with liquid paraffin, provided the seed was drilled within 1 day after being treated. The effectiveness of the treatment decreased with delay in drilling. Neither treatment had any effect on the germination of the seed. K. D. JACOB

Experiments on the control of finger-and-toe (disease) in cabbages by the use of mercuric chloride and other substances. N. C. PRESTON. Harper Adams Agr. Coll., Newport, Salop. *Welsh J. Agr.* 4, 280-95(1928).— $HgCl_2$ was compared with a no. of other disinfectants for the control of the finger-and-toe disease of cabbage and cauliflower in a series of expts. extending over a period of 3 years. The best results were obtained with 0.1% solns. of $HgCl_2$, a 30% control of the disease being obtained in 2 seasons and 70% in the third season. A marked stimulation of growth was obtained with plants treated with Me green, 0.005% soln., malachite green, 0.005-0.01% solns., and $HgCl_2$, but with the 2 dyes this effect was not noticeable after 3-4 weeks. Me violet and brilliant green also were ineffective. Uspulun, 0.5% soln., gave good but somewhat inferior results to those obtained with $HgCl_2$, 0.1% soln. 0.2% solns. of $HgCl_2$ not only failed to check the disease but also seriously affected the growth of the young plants. The investigations are being continued. K. D. JACOB

Fertilizing value of Baltimore sewage sludge (KEEFER, ARMELING) 14. The behavior of the Sb electrode in buffered and unbuffered solutions (LAVA, HEMEDDES) 2. Dehydration of silica (HOCKENYOS) 7. Disinfectants and insecticides (RIDEAL, RIDEAL, SCRIVER) 18. Excess HNO_3 in phosphate determinations (HOCKENYOS) 7. Notes on dual emulsions, with examples of interest in the spraying of trees (WOODMAN) 2. Nutritional contents of sediments in settling basins (NOVAK) 28. Pyrohymatomelanolic acid (KREULEN) 10. Relation of cotton root rot and *Fusarium* wilt to the acidity and alkalinity of the soil (TAUBENHAUS, *et al.*) 11D.

Fertilizer. C. W. MARTIN. Brit. 292,809, Sept. 9, 1927. Flue dust or K_2SO_4 is mixed with lime, powdered slag (which may in part be replaced by steamed bone flour), NH_4 sulfate and "agricultural salt."

Fertilizers. H. R. READ. Brit. 293,168, May 21, 1927. Waste org. nitrogenous material is heated to above 100° under pressure in the presence of NH_3 and H_2O . The viscous mass or liquor thus produced is then dried. Leather, hair, felt, wool, shoddy, silk, hoofs, horns, feathers, fish, dried blood and gelatinous material may be used.

Fertilizer. I. G. FARBEININD. A.-G. Brit. 292,098, June 13, 1927. Urea is heated until evolution of NH_3 ceases and the product may be mixed with other fertilizer ingredients, or its constituents such as ammeline or cyanuric acid may be sep'd. and used in fertilizers.

Fertilizer. I. G. FARBEININD. A.-G. Brit. 292,068, June 11, 1927. Mixed fertilizers are prep'd. by spraying or atomizing 2 or more inorg. fertilizing materials such as HNO_3 , H_2SO_4 and H_3PO_4 by use of NH_3 gas or gases contg. NH_3 . NH_4 salts may be used instead of the acids and salts of K, or other fertilizing salts may be added.

Fertilizer. NICODEM CARO and ALBERT R. FRANK. Fr. 642,659, Oct. 21, 1927. An alk. fertilizer is prep'd. by causing NH_3 to act at $500\text{--}850^\circ$ on natural or artificial carbonates until a product is obtained contg. 10–30% of N. The product is further treated to decomp. any carbonate remaining. Cf. C. A. 23, 234.

Fertilizers. SOC. ANON. DES CHARBONS ACTIFS ÉDOUARD URBAIN. Fr. 643,521, Apr. 8, 1927. K phosphates and HCl are prep'd. by heating phosphoric acid with KCl. The product is KPO_3 , which by hydration can be converted into $\text{K}_2\text{H}_2\text{P}_2\text{O}_7$ and KH_2PO_4 .

Fertilizers. SOC. ANON. DES CHARBONS ACTIFS ÉDOUARD URBAIN. Fr. 643,542, Apr. 9, 1927. N is introduced into the fertilizers described in Fr. 643,521 (preceding abstr.) either by fixation with NH_3 , urea, cyanamide, etc., or by introducing N bases, such as NH_3 , urea, etc., into the mol., *e. g.*, $\text{PO}(\text{OK})(\text{ONH}_2)(\text{NH}_2)$.

Fertilizer. UNION AGRICOLE DE JODOIGNE. Fr. 643,178, Oct. 28, 1927. A completely sol. fertilizer is made by reaction of H_2SO_4 and a mixt. of a natural phosphate, rich in phosphoric acid and CaCO_3 , with KCl, and introduction of $(\text{NH}_4)_2\text{SO}_4$. The product of reaction is allowed more or less to solidify and is then neutralized by a phosphate poor in CaCO_3 , dried and ground.

Cultivating edible fungi. JOSEF SZÜCS. Austrian 109,419, Dec. 15, 1927. Solid or semi-solid carrier materials are mixed with nutrient solns. contg. carbohydrates and suitable salts, and the mixt. is infected with bacteria to produce a fermentation similar to that of horse manure. After fermentation, the mixt. is inoculated with mycelium or spores. In an example, *Aspergillus* is cultivated in a medium initially contg. molasses, superphosphate and $(\text{NH}_4)_2\text{SO}_4$.

Fungicide. HUGO L. KLEINHANS. Can. 286,408, Jan. 15, 1929. CuCO_3 (40%) is mixed with 60% S to form a fungicide capable of suspension in water, which at the same time has fertilizing value. The mixt. may be used either dry or as a wet spray.

Colloidal fungicides and insecticides. J. RILEY & SONS, LTD., W. H. BENTLEY and W. M. COATES. Brit. 293,084, March 23, 1927. Reagents which will produce the desired dispersed product are mixed in the presence of gelatin or other suitable jelly-forming substance, and the sol. salt formed may be removed by washing or by permitting efflorescence. Examples are given of the prepn. of products contg. colloidal S, Pb arsenate and other substances.

Insecticide. SEISHIRO NISHIMURA. Can. 286,953, Feb. 5, 1929. Tobacco ($1/4$ lb.) is boiled for 20 min. in 1 gal. water; 2 lbs. of fish offal is boiled in 1 gal. of water for 20 to 30 mins. and then passed through a sieve to remove the solids. The two solns. are mixed together and heated to boiling and then allowed to cool. To this mixt. there is added liquid soap obtained by boiling $3/4$ lb. soap with 1 gal. of water, to which liquid soap is added 6 fluid oz. of moth spray, as petroleum and pyrethrum powder or flytox. The insecticide is sprayed on the plants.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Phosphorylation and alcoholic fermentation of sugars. CARL NEUBERG AND MARIA KOBEL. Kaiser Wilhelm-Institut für Biochemie. *Ann.* 465, 272-82(1928).—The rate of evolution of CO₂ from sugars fermented with dried yeast or maceration juice in the presence of K phosphate or traces of Mg hexosediphosphate and of PhMe is compared with that from Na hexosemonophosphate similarly treated. The curves for dextrose, levulose and sucrose are very similar, but the induction period is much longer with the 1st. The fermentation of the hexosemonophosphate, however, begins only slightly more rapidly and is soon retarded in such a way that after a few hrs. it has proceeded to a much smaller extent than has that of the uncombined sugars. These results are obtained with yeasts and sugars of varying sources and show that a hexosemonophosphate cannot be, at least in its normal stable form, an intermediate compd. in the fermentation of sugars.

C. J. WEST

Studies on fermentation products. I. Fractional distillation of saké. TUNETO HIGASHI. *Bull. Inst. Phys.-Chem. Research* (Tokyo) 7, 500-26(1928); *Abstracts* 1, 45-7.—Eighteen l. of saké was fractionally distd. Fraction I (b. 50-70°) contained only AcH. Fraction II (b_m 70-1°) contained EtOH and PrOH. Fractions III and IV (at low pressure, b. <60°) contained EtOH, PrOH, AmOH, terpenes from the barrel, and surgi resin, surgi being the wood out of which the barrel was made. Fraction V (b. 50-60° at low pressure) contained H₂O, furfural, AcOH, traces of formic, propionic, levulinic and pyruvic acids, ethyl acetate, lactate and pyruvate. II. Color reactions. *Ibid* 527-39, *Abstracts* 1, 47-50.—The reagent used is obtained by dissolving 1 g. vanillin in 200 cc. concd. H₂SO₄. A drop of the substance to be tested is mixed with 2 cc of reagent; a color develops. By adding gradually drops of H₂O, the color changes progressively as reported in the table:

No of H ₂ O drops					
	0	1	2	64	128 (On standing overnight)
AcH	yellow	yellow	dark green	bluish green	light blue, transparent
EtOH	yellow	yellow	green	blue	light blue, transparent
PrOH	yellow	orange-red	intense purplish red	intense red- dish purple	dark purple, as resinous ppt.
AmOH	red	scarlet-red	dark red	purplish red	dark red, as oily drop
EtOAc	yellow	yellow	greenish yellow	light green	light blue ppt.
Pyruvic acid	yellow	green	deep green	indigo blue	blue ppt.
Levulinic acid	yellow	greenish yellow	greenish blue	indigo blue	blue ppt.
MeCOEt	orange-yellow	dark green	dark bluish brown	deep indigo blue	blue ppt.
Saké distil- late, b. 78- 85°	orange-yel- low	orange-red	purplish red	intense purple	blue ppt.

ALBERT L. HENNE

Comparative brewing trials with certain new and commercial varieties of hops. W. T. SMITH AND A. J. C. COSBIE. *J. Inst. Brewing* 34, 565-70(1928).—Comparative brewing trials were made with 8 varieties of hops, whose origin, valuation and gravimetric and biological grading are given.

PETER J. F. WEBER

Small-scale brewing in the laboratory. F. E. DAY. *J. Inst. Brewing* 34, 570-3 (1928).—A description of, and results obtained through use made of lab. equipment by D. in the making of small-scale brewings which would give results comparable with technical operations.

PETER J. F. WEBER

Brewing liquor. MARC H. VAN LAER. *Petit j. brasseur* 1928, 903, 927; *Brewers J.* 64, 452-4(1928).—Because of the restrictive action of the reaction of the mash on diastase, p_H regulation is important. Primary and secondary phosphates control the reaction of the wort, and expts. show it is possible to calc. the p_H from the formula $p_H = p_K$ plus $\log (A/B)$, in which p_K is a const. characteristic of the acid (7.1 for pri-

mary phosphate) and A and B represent the amounts of primary and secondary phosphates. Addn. of Na_2CO_3 or CaCl_2 in definite amounts to worts gives p_H values in accord with the formula. Na_2CO_3 increases p_H through formation of secondary phosphate from primary. Ca and Mg salts decrease p_H through formation of primary phosphate from secondary, with pptn. of tertiary phosphate, within limits depending upon the quantity of phosphates present; they have a greater influence on strong than on weak worts, also a greater action with a wort made with alk. water. Regulation of the p_H through treatment of brewing water can be had by (a) decarbonation by boiling water, which is costly, or lime-water treatment, which requires careful control but gives excellent results, (b) Burtonization, which is limited by the effect of Ca and Mg salts and compn. of water, and (c) acid treatment, which is most flexible but requires very careful control. Water treatment also requires a modification in brewing methods because of the change it produces in diastatic activity.

PETER J. F. WEBER

The investigation on the preservative principles of hops. FRANK L. PYMAN *J. Inst. Brewing* 34, 447-50(1928); cf. *C. A.* 22, 3484.—A review. P. J. F. W.

Report on the preservative principles of hops. IX. The influence of special methods of drying at low temperatures upon the antiseptic properties of hops. J. J. HASTINGS AND T. K. WALKER. *J. Inst. Brewing* 34, 556-65(1928); cf. *C. A.* 22, 1432.—Hops dried by four different methods, namely: (1) commercial drying, (2) in a current of air at 40° , (3) in a steam-heated vacuum oven at 40° , and (4) in a water-heated vacuum oven at 40° , when graded biologically by the Chapman method (cf. *J. Inst. Brewing* 25, 18), gave figures of 100, 162, 140 and 150, resp., whereas grading gravimetrically (*C. A.* 22, 1432) resulted in figures of 100, 100, 78.3 and 94.4, resp. After 6 months' storage, however, the two methods gave practically identical results, which compared with the gravimetric grading of the freshly dried hops. Green hops were then compared with specially dried and commercially dried hops and gravimetrically gave the same figures, but biologically the figures were 237, 133 and 100, resp. In the green and the specially dried hops no other antiseptics were found than the α and β resins. Biol. tests with septs. and combinations of the resins in the hops showed a greater antiseptic power in the β resin of the green and the specially dried hops; this is attributed to the presence of a large proportion of cryst. lupulone in the β portion of the soft resins. This is partly destroyed by commercial drying and also by storage of the specially dried hops. The antiseptic power of the lupulone, which was still in evidence after boiling the hops with wort or water for one hr., was almost entirely destroyed by a two-hr. boiling period.

PETER J. F. WEBER

The tannin of hops. F. EMSLANDER. *Petit j. brasseur* 1928, 1292; *Brewers J.* 65, 49-50.—The combination of the tannin of the hops with the protein of the wort, which takes place principally in the boiling of the wort in the kettle, is comparable to a tanning process. Just as a hide treated with a strong tannin solution differs from a hide treated with increasing concentrations of tannins, so differences in stability of the proteins in beer may be attributable to "strong or weak" tannins in the hops. Whether the tannin is "strong or weak" is tested with FeCl_3 and gelatin. A test tube with 10 cc. of solidified 25% gelatin to which 2 cc. of 1% FeCl_3 per 100 cc. of soln. has been added is covered with a layer of distd. water. Three hop cones are then placed in the water and on this is put a layer of toluene to prevent infection. If after standing 100 hrs. the whole mass of gelatin becomes dark colored, the hop tannins are considered as weak. If a very dark-colored layer is produced just below the water, then the tannins are considered as strong. Tested by this method the hops of 1927 contained softer resins than those of 1926; and new hops show a stronger tannin than the old hops. Soft tannins in hops are to be preferred to strong tannin, because the strong tannins merely "tan" the outer surface of the protein particle, whereas the soft tannins penetrate the protein complex and therefore these are more thoroughly eliminated. Light and heat (pasteurization) favor protein haze in beers, the cause of each being due to an acceleration of the tanning process. Removal of tannin in the brewing process is very important, particularly in beers intended for export.

PETER J. F. WEBER

The biological stability of beer. R. H. HOPKINS AND J. E. FRASER. *J. Inst. Brewing* 34, 387-402(1928).—The factors investigated as relating to the biological stability are (1) p_H of beer during storage, (2) content of nutrients, particularly assimilable nitrogen, (3) races of organisms present, their quantity and vitality, and the effect of the races of organisms upon each other, (4) effect of antiseptic substances, i. e., hop resins and added preservative, and alcohol content. Other conditions being equal, the beer with p_H approx. 4.0 was most stable. Adding varying amounts of a pepsin digestion of wheat gluten to wort had practically no effect on the resulting beers' stability, indicating that assimilable nitrogen is of little significance. Addition of hop

infusion to worts increased the stability of the beers and the antiseptic value of hops is therefore of considerable importance. The detn. of p_H of the beer at racking and "correlation of the electrometric titration with stability, for each class of beer, should enable the brewer to predict the stability of freshly brewed beer," but the amount and nature of the infection in the beer is of greatest importance. P. J. F. W.

The determination of sulfur dioxide in beers. N. C. BEETLESTONE. *Brewers J* 64, 143-44(1928); cf. *C. A.* 22, 3484.—Direct estn. of SO_2 in beer, may in certain circumstances prove of considerable value, especially where it is only necessary to det. if the beer contains SO_2 below the legal limit. For accuracy and reliability, however, a distn. method must be employed. Two distn. methods are favored: that adopted by the Council of the Institute, of Brewing (cf. *J. Inst. Brewing* 1926, 172), in which the SO_2 is distd. into Br water and the H_2SO_4 formed detd. by pptn. as $BaSO_4$, and the Monier-Williams method in Report 43, of the Ministry of Health. In this method the SO_2 is distd. from acidified beer into H_2O_2 and H_2SO_4 formed is titrated with 0.1 *N* NaOH, with bromophenol blue as indicator. Provided a blank titration on the H_2O_2 is made and 0.05 *N* or 0.04 *N* NaOH used, this method gives good results. However, the results are distinctly different from those of the Institute method, which appears to be influenced by the hopping rate of the beer. Volatile S compds. cause a higher SO_2 figure to be obtained by the Institute method. If a S trap (consisting of a flask with 1% $CuSO_4$ to be placed between the boiling flask and condenser) is used, the result of the Institute method compares well with that of Monier-Williams. This, however, increases danger of leakage through increase in number of joints and also complicates the procedure. B., therefore, considers the Monier-Williams method to be more accurate and more rapid.

PETER J. F. WEBER

Composition of wines of the Malaga type. E. ŠVAGR, J. LUKAS AND A. JILEK. *Chem. Listy* 22, 29-34(1928).—Malaga wines manufd. in Czechoslovakia differ little in chem. compn. and alimentary value from the original products. The calorific value of the above wines is very nearly the same as that of malt wines of the Malaga type both ordinary and medicinal. In compn., however, the malt Malaga types differ from the true Malaga wines in their high content of lactic acid and dextrin, and absence of tartaric acid. While unmatured malt Malaga wines contain sucrose, this is not a sp. constituent. The mineral content of the latter wines is only half as great as for true Malagas, and is remarkable for its low K and high H_2PO_4 content.

B. C. A.

Character in pot-still whiskey. S. H. HASTIE AND W. D. DICK. *J. Inst. Brewing* 34, 17, 94(1928); cf. *Ibid* 32, 209. "Character" is the term used to designate the palate flavor of whiskey, and whiskeys are distinguished from one another by their character, and not by differences in their chemical compn. Acids, esters, aldehydes, furfural, alcohols, and probably other substances affect the character. The present study was made on furfural, as to whether this is influenced by the compn. of the wash (fermented mash) or actual operation of the distn. processes, or both, and what factors control the production of furfural in the stills. Fractional distn. showed that furfural added to the wash is transferred to the distillate mainly at 76.7°, and additional furfural was obtained at the end of the distn. due to slight charring. A wash with added acid but with no furfural added also gave furfural at the end of the distn. Because of the difficulty of obtaining a wash of identical compn. for all the expts., an artificial wash was prepd. contg. arabinose and xylose, the pentoses present in wash. Tests made with this wash with added acids, showed that furfural is only produced when the acid concn. is high; therefore the furfural is not formed in the pot still by the action of acids on pentoses. The conclusion was then reached that furfural is produced by superheating or charring of the wash in the still through direct fire heating. Tests made with pale malt ext., to which alcohol was added, gave no furfural except if distilled with strong acid. Amber, crystal and roasted malt gave furfural in the distillate. Xylose, treated with acid, boiled under reflux and distd., gave furfural if heated by direct flame. These tests confirmed the above conclusion. The formation of furfural having been shown, it was attempted to det. what happens to the furfural present in the wash still distillates, low wines, foreshots and feints, with alcohol contents of approx. 20%, 70%, and 33% by vol., resp. The furfural contents in parts per 100,000 are 1.9, 2.0, 2.0 and 3.0, resp. The sepn. of these fractions is detd. by previous experience, not by any scientific system. Max. furfural passes over at alc. strengths of 32 to 67% by vol., and a temp. of 73-78°; a highly rectifying still confines the furfural to a smaller number of fractions. The presence of pentoses in peat being known, this is also a possible source of furfural and is noted but not studied. Yeast distd. with and without acid did not yield furfural. Seventeen whiskeys varied from

2.2 to 6.3 parts furfural per 100,000 parts absolute alcohol. Furfural content was not in accord with commercial appreciation of the whiskeys. However, furfural additions to a low-furfural whiskey did enhance the flavor up to a point over which it was objectionable. Furfural in maturing of the whiskey is considered of little importance, since as has been shown (Crampton and Tolman, *C. A.* 2, 685) the furfural content increased very slightly on ageing.

The water content of yeast cells. F. E. DAY. *Brewers J.* 64, 99-100(1928).—A criticism of the findings of N. C. Beetlestone (*C. A.* 22, 1649) and R. H. Hopkins (*C. A.* 22, 1650).

Hydrostatic pressure and the yeast cell. N. C. BEETLESTONE. *Brewers J.* 64, 139(1928).—An answer to F. E. Day (above).

PETER J. F. WEBER

PETER J. F. WEBER

PETER J. F. WEBER

A milk-fermenting yeast (AYYAR) 11C. Decolorizing carbon (U. S. pat. 1,700,342 18.

Fermentation processes. S. BAKONYI (to Deutsche Hydrier Werke A.-G.). Brit. 293,015, June 30, 1927. In the production of EtOH, PrOH, iso-PrOH, BuOH, acetone and the like from amylaceous materials, production of lactic or butyric acids, etc., natural mixed cultures of bacteria and yeast are used and these may be submitted to selection as by allowing them to grow in contact with a small quantity of the desired product to obtain organisms of greater resistance. Filter bodies of slag or broken stone may be used as carriers for the cultures.

Vinegar. SOCIÉTÉ H. GOUTHIERE ET CIE. Fr. 642,697, Mar. 23, 1927. In fermentation for the production of vinegar, fibers of fir wood or other varieties from which resin is first removed are used instead of the usual beech shavings.

Preventing corrosion by spirit. BENZOL-VERZAND G. M. B. H. Ger. 469,921, May 26, 1926. Addn. to 447,526. The corrosive action of spirit is prevented by adding an alkali benzoate before rectifying by distn.

Distilling or evaporating mashies, beer worts, etc. H. KOCK and R. QUIR. Brit. 292,518, June 20, 1927. The material is intensively heated with steam in a tube and the steam and liquid mixt. are raised above the liquid level in a closed current and the mixt. is returned under full pressure through downwardly directed jets on to the surface of the liquid. An app. is described.

Yeast. H. BÜCHER. Brit. 292,202, Feb. 19, 1927. Yeast is produced in an aerated wort, which is maintained slightly acid. The nutrient compds. used either produce no acid (in which case a small proportion of acid is added) or produce just sufficient acid to maintain the optimum acidity so that neutralization is unnecessary and the nutrients used do not form insol. acid compds. Carbamide may be used as a source of N and use of compds. of I, Br, Fe, etc., is referred to. Liquid sepd. from the yeast produced may be used again with an admixture of fresh nutrient materials. Cf. *C. A.* 23, 1211.

Yeast preparation. RICHARD WILLSTÄTTER and HARRY SABOTKA. U. S. 1,701,200, Feb. 5. After initiating autolysis and liquefaction of yeast (suitably by heating with corn sirup) the liquefied mass, which is heated to about 40-50°, is admixed with substantially an equal quantity of a monosaccharide such as cryst. glucose, and the mixt. is heated to 85-100° to obtain a product suitable for use in bakery products or confectionary.

Activating yeast. ERNST PRIBRAM and HUGO WERTHEIM. Austrian 111,532, July 15, 1928. The propagation of yeast is stimulated and the enzymic activity of the product is improved by adding to the usual nutrient media a small quantity, e. g., 5%, of carrot juice and a trace of a sol. salt of a metal, e. g., Mn, Fe, Cu, Zn, Al, or Cr.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Crystal form of atoxyl [sodium *p*-aminophenylarsonate]. G. CESARO. *Mem. soc. roy. sci. Liège* 12, 1-11(1924).—The results obtained by Mélon (*C. A.* 17, 2629) and by Gilta (*C. A.* 17, 2167) are discussed in regard to the relationship between the two different orientations of the crystal adopted.

Evaluation of nitris aethylicus cum spiritu. L. VAN ITALLIE, A. J. STEENHAUER and A. HARMSMA. Univ. Leiden. *Pharm. Weekblad* 66, 15-22(1929).—A new method of detg. the EtONO content of sweet spirits of niter consists in oxidizing the EtONO

to EtONO_2 by means of KClO_3 and iodometric titration of the excess KClO_3 . To 10 cc. of the sample add 10 cc. of 2 *N* KClO_3 and 5 cc. of dil. H_2SO_4 . Allow the mixt. to stand 5 min. in a volumetric flask with occasional shaking. Dil. to 100 cc. and to a 10-cc. aliquot add 2 cc. NH_4OH and 3 cc. H_2O . Boil in an unstoppered flask to a vol. of about 10 cc., cool, add 1 g. KBr and 15 cc. concd. HCl , insert the stopper and after 5 min. add 1 g. KI in 10 cc. H_2O . Titrate the liberated I with 0.1 *N* $\text{Na}_2\text{S}_2\text{O}_3$. Each cc. of *N* KClO_3 consumed is equiv. to 37.5 mg. EtONO . A. W. DOX

Microchemical study of official alkaloids. L. ROSENTHALER. Univ. Bern. *Apoth. Ztg.* 44, 40-3(1929).—Some 30 alkaloids were examd. in detail respecting the character of ppts. obtained with certain alk. reagents. Eighteen microchemical illustrations are shown. W. O. E.

Examination of dry extracts. A. KOENIG. Tech. Hochschule Braunschweig. *Apoth. Ztg.* 44, 74-6(1929).—A comparative study of dry exts. prepd. *via* Krause (D. R. P. No. 297,388) with standard official preps. and others specially made in the lab showed no marked differences in quality of 4 preps. examd. W. O. E.

Anatomy and chemistry of drugs. Protein tubes therein. TH. BOKORNY. *Pharm. Ztg.* 74, 57-60(1929).—A histological and chem. study of *Potentilla tormentilla* and *Rosa centifolia*, in sections treated with very dil. solns. of certain bases (caffeine, antipyrine, etc.) in order to render visible by agglomeration the active reserve proteins as "proteosomes." W. O. E.

Dermal salve. C. A. ROJAHN, MAX HERTER AND GERTRUD HAMANN. Univ. Halle-Wittenberg. *Apoth. Ztg.* 44, 105-6(1929).—This prepn. contains as essential ingredients hydrophile fatty material 16, alum 11-12, active Cl (as hypochlorite) 0.05%, together with a little NaCl . W. O. E.

Eutirsol. H. SCHREIBLER. Tech. Hochschule Berlin. *Apoth. Ztg.* 44, 106-7(1929).—A new thiophene-sulfur prepn. from the distn. products of Seefeld shale. It is a mobile, bright yellow liquid of faint odor, sol. in nearly all org. solvents, has a $d_{20} 0.96$ and contains 12-13% S almost entirely in the form of thiophene compds., which constitute about one-half the oil. While it is inclined to darken in the light and air, it is in combination with suitable salve bases, expected to prove more satisfactory than ichthol, since it contains all the valuable therapeutic ingredients of the latter and none of its objectionable features. W. O. E.

Bromometric and rhodanometric estimation of essential oils. I. H. P. KAUFMANN AND H. BARICH. Univ. Jena. *Arch. Pharm.* 267, 1-27(1929).—From a large no. of expts. it is shown that the addn. of Br dissolved in NaBr-MeOH proceeds to a very definite point in the case of geraniol, linalool, terpineol, anethole, thymol, citral, vanillin, cinnamaldehyde, carvone, geranyl acetate and linalyl acetate, corresponding to a stoichiometric relationship of the reacting substances, from which fact it is possible to develop true I values. Similar conditions obtained in the rhodanometric estn. of citronellol, geraniol, linalool, terpineol, anethole, thymol, citral, citronallal and geranyl and linalyl acetate. W. O. E.

Organotherapeutic preparations in pharmacopeias, and their methods of examination. KARL NEUMAYER. Univ. Wien. *Arch. Pharm.* 267, 27-30(1929).—An address. W. O. E.

Detection of cantharidin. R. FISCHER. Univ. Innsbruck. *Arch. Pharm.* 267, 31-5(1929).—A highly detailed procedure, involving distn. and sublimation, for the isolation of cantharidin from the urine, stomach contents and other organs, preliminary to its microscopic recognition, in a diln. as high as 1:300000. The method also permits the detection of minute amts. of cantharidin in plasters. W. O. E.

Estimation of potassium iodide in tincture of iodine via D. A. B. 6. J. WEICHERZ. *Arch. Pharm.* 267, 36-42(1929).—The excess values obtained by the official Ger. method for the tincture are due partly to formation of MnO_2 , partly also to oxidation of I to HIO_2 . The formation of MnO_2 can be prevented by addn. of MnSO_4 , which likewise tends to inhibit the formation of HIO_2 . The HIO_2 formation can be counteracted by addn. of CCl_4 . Reduction of very small amts. of HIO_2 by $\text{H}_2\text{C}_2\text{O}_4$ is facilitated by the presence of MnSO_4 . Addn. of CCl_4 also prevents loss of I through escaping CO_2 . Estn. of free I and of the iodide can be effected in either one or 2 sep. samples. The results yielded by the Weichherz-Klinger method are accurate within the usual limits of error peculiar to titration. W. O. E.

Superfluous new pharmaceutical preparations. "Nautisan." CHEMOSAN-UNION AND FRITZ FIEZOLDT A.-G. *Chem.-Ztg.* 52, 777(1928).—An attempt to refute the recent criticisms (cf. C. A. 22, 4202) relative to the above subject matter. Superfluous new pharmaceutical preparations. HANS PICK. *Ibid.*—A reply to the above. W. O. E.

Determination of ionone. R. D. HENDRIKSZ AND A. RECLAIRE. *Perfumery*

Essent. Oil Record 19, 493(1928).—Reflux 5 cc. of the sample 2 hrs. with a mixt. of 15 g. $\text{NH}_4\text{OH} \cdot \text{HCl}$, 18 g. potash and 37.5 g. H_2O . After boiling, pour the hot mixt. into a separatory funnel, draw off the aq. layer and wash the oximated oil 3 times with hot brine, filter as hot as possible (which can be done in a little drying oven at about 100°). In about 0.5 to 1 g. of the oximated product det. the N *via* Kjeldahl (Gunning modification as used in the method for detg. citronellal in Java citronella oil. Calc. the ionone content by means of $x = 53.82 a / (14 - 0.042 a)$, in which a = no. of cc. 0.5 N H_2SO_4 required for 1 g. oximated oil. W. O. E.

Commercial evaluation of cloves. W. A. N. MARKWELL AND L. J. WALKER *Perfumery Essent. Oil Record* 19, 496-7(1928).—Following a discussion of 5 different procedures, a 6th is suggested as being rapid and yielding results closely approximating those obtained by the U. S. P. method, and moreover sufficiently accurate for the evaluation of cloves to be used for oil distn. Weigh out accurately in a tared Petri dish 0.5 to 1 g. of the powdered sample (No. 20 powder), spread in a thin layer on the floor of the dish and heat at 110° to const. wt. The loss in wt. gives the total amt. of volatile matter inclusive of moisture, which latter is detd. meanwhile *via* Dean and Stark. Calc. % of volatile substances other than H_2O by difference. The entire detn. requires only 8 hrs. or less. W. O. E.

Rheuma-Sensit. C. A. ROJAHN. Univ. Halle-Wittenberg. *Apoth. Ztg.* 44, 28-9(1927); cf. *C. A.* 22, 1652. An analgesic stated by the analyst to be essentially a mixt. of soap 40, vaseline oil 15, lanolin or adeps lanae 5, free fatty acids 10, Water 15, salicylic acid as K salicylate 10, essential oils, camphor and menthol 5%. W. O. E.

Simple evaluation of spiritus aetheris. F. WRATSCHKO. *Pharm. Presse* 34, 5 (1929).—In a recent paper (cf. *C. A.* 23, 1212) a correction should be made in the value to be calcd. for $y = 72(20 - k)/d$; 72 should read 7.2. W. O. E.

Jasmine, jasmone and jasminaldehyde. A. ROSENTHAL. *Riechstoffindustrie* 3, 228-30(1929).—A discussion of the enfleurage and extn. processes for isolating the odorous principles from the flowers in connection with the various attempts to reproduce these principles in the lab. W. O. E.

New esters. WILLIBALD RENDERN. *Riechstoffindustrie* 3, 231(1929). Among the newer esters considered are formates, butyrates and phthalates. Of special interest perhaps are: benzyl butyrate for jasmine and rose, citronellyl butyrate in lavender and rose compns., cinnamyl butyrate in eau de Cologne and anisyl isobutyrate as fixative. W. O. E.

Fluid extracts of domestic drug plants. I. KROEBER. *Pharm. Zentralhalle* 69, 115-7, 357-8, 386-9, 438-9, 565 7, 663 5, 727 9, 807-9(1928); 70, 4 6(1929); cf. *C. A.* 22, 1213.—Ext. *Meliloti officinalis* d_{15} 1.122, dry residue 38.05%, ash 3.60%; ext. *Staphis cerasorum* d_{15} 1.0399, dry residue 16.30%, ash 2.30%; ext. *Anagallis arvensis* d_{15} 1.075, dry residue 27.20%, ash 3.40%; ext. *Euphrasiae officinalis* d_{15} 1.79, dry residue 21.00%, ash 2.35%; *Spiraeae ulmariae* d_{15} 1.0696, dry residue 15.90, ash 2.15%; ext. *foliorum vaccinii myrtilli* d_{15} 1.0293, dry residue 13.65, ash 1.00%; ext. *Eupatorium cannabini* d_{15} 1.018, dry residue 12.25%, ash 1.55%; ext. *Erythraee centaurei* d_{15} 1.065, dry residue 22.75, ash 1.05%; ext. *Verbenae officinalis* d_{15} 1.0427, dry residue 16.25%, ash 2.90%. W. O. E.

Estimation of tannin in drugs. O. LINDE AND H. TEUFER. *Tech. Hochschule Braunschweig. Pharm. Zentralhalle* 70, 21-6, 53 60(1929).—Of the very large no. of methods for the detn. of tannin already described in the literature, 4 (involving hide powder, SnCl_2 , $\text{Cu}(\text{OAc})_2$ and volumetric methods) were selected for the present comparative study. There was, however, no agreement in the results obtained. While the hide-powder method was servicable in every case tested, it is too involved for the av. apothecary's lab. As compared with the hide-powder method, the SnCl_2 and $\text{Cu}(\text{OAc})_2$ soln. methods gave too low values, but are well suited to the demands of the apothecary. The SnCl_2 method cannot be used with gambir. In operations with the Loewenthal method the actual content of tannin is not detd. but rather the reduction capacity as compared with that of tannin. With drugs contg. alkaloid compd. of tannin, it is necessary to decompose the latter with alkali preliminary to elimination of these bases and before detn. of the tannin content. A comparative summary is given of the tannin content of some 10 crude drugs as detd. by the 4 methods. W. O. E.

Tinctura ferri pomata. I. G. OBERHARD. *Pharm. Ztg.* 74, 13-4(1929).—An exptl. study of the prepn. and behavior of this Fe compd. of malic acid. Contrary to earlier statements in the literature this prepn., official in several European pharmacopeias, contains Fe^{III} only when freshly made, the older preps. contg. the Fe mostly or entirely in bivalent form. W. O. E.

Improved method for the examination of pharmaceutical preparations by means of greatly extended capillary pictures, and the analytical quartz lamp. C. A. ROJAHN. *Pharm. Ztg.* 74, 14(1929).—A commentary on the paper of like title by Rapp (cf. C. A. 23, 931). W. O. E.

Microcrystallization of alkaloids. HANNS BECKMANN. *Pharm. Ztg.* 74, 28-9 (1929); cf. C. A. 22, 4718.—A microscopical study has been made of the behavior of aq., acid or salt solns. of certain alkaloids on slow evapn., and of the appearance of their residues with or without the addn. of certain reagents. Among the alkaloids examd., the solvent used, the reagent if any subsequently added, and the crystn. picture, the following are given in the order indicated: aconitine in dil. HNO_3 , addn. of AgNO_3 , highly refractive rods; atropine in dil. HCl , NaOH , needles; brucine in HCl , KOH , thin needles and prisms frequently in fan-shaped forms; codeine Na_2CO_3 , —, rhomboidal prisms; caffeine in NaCl 1:100, —, axial angular squares; cocaine in dil. acids, $\text{K}_3\text{Fe}(\text{CN})_6$, rosettes; narcotine in dil. HCl , NaOAc , delicate prisms; papaverine in alc., —, radiating leaflets; papaverine in AcOH , NaOAc , tiny leaves; thebaine in dil. acids, NaOH or NH_4OH , quadratic crystals; strychnine in $\text{K}_2\text{Cr}_2\text{O}_7$, —, yellow stars often in tufts; strychnine in $\text{K}_3\text{Fe}(\text{CN})_6$, —, mat golden radiating crystals; veratrine in dil. HCl , K_2CrO_4 , coalescing stellar aggregates; morphine in NaOH , $(\text{NH}_4)_2\text{CO}_3$, crystal skeletons. In this connection the identification of minute traces of alkaloids by means of their sublimates is discussed. W. O. E.

Estimation of essential oil in folia menthae piperitae. HORKHEIMER. *Pharm. Ztg.* 74, 45(1929).—A commentary on the Ger. Pharm. method for the evaluation of peppermint, including results obtained on a few com. samples. W. O. E.

Pharmacognostic notes. L. ROSENTHALER. Univ. Bern. *Pharm. Ztg.* 74, 75-7(1929).—The paper includes observations on the identification of nitrates in drugs, two *Cinchona* barks (*castrona* and *naradjada*) from S. America, Flores Cinae, Japanese ginger and so called Indian tragacanth (*Sterculia*). W. O. E.

Taste corrigent for urea. H. ESCHENBRENNER. Hamburg. *Pharm. Ztg.* 74, 91-4(1929).—A discussion of various formulas for masking the taste of urea when used as a diuretic. W. O. E.

Evaluation of lecithprotein. C. MASSATSCH. *Pharm. Ztg.* 74, 94-5(1929).—Extn. of fully desiccated egg yolk (preferably in vacuum at 60°) with petr. ether (0.40-60%) yields a dry friable yellowish white residue (lecithprotein) contg. about 25% lecithin, which latter may be in turn completely isolated by boiling alc. The term lecithprotein (Lecithinalbumin) should apply only to a product emanating from egg yolk. W. O. E.

Estimation of morphine in opium, in opium extract and in its tinctures. THEODOR BERTHM. Univ. Berlin. *Apoth. Ztg.* 44, 88-91(1929).—After discussion of the official Ger. methods, the following procedure is suggested for opium: Triturate 3.5 g. of moderately powdered opium with 3.5 cc. of H_2O , transfer to a flask with H_2O so that the total wt. is 31.5 g. After 1 hr. (with frequent shaking the while), pass the liquid through a dry (8-cm.) folded filter, and to 21 g. of the filtrate (= 2.44 g. opium) add 1 cc. of a mixt. of 1 g. NH_4OH and 83 g. of H_2O , mix and pass immediately through a dry folded 8-cm. filter into a tared flask. Remove 18 g. (= 2 g. opium) of the filtrate to a small separatory funnel, the lower constriction of which just above the cock is closed by a small pledget of cotton, wash out the flask twice with 1-cc. portions of H_2O , add 10 cc. of EtOAc and 2.5 cc. of the mixt. of 17 g. NH_4OH and 83 g. H_2O , close the separatory funnel and shake 10 mins., allow to stand 15 mins. with occasional agitation of the liquid, then adjust the separatory funnel to a suction flask, draw off the liquid and wash the residual morphine twice with 2.5-cc. portions of H_2O , closing the separatory funnel during each washing, dissolve the morphine crystals in 10 cc. of 0.1 N HCl , dil. with 25 cc. H_2O and titrate with 0.1 N KOH in the presence of 2 drops of methyl red soln. Continue finally *via* the D. A.-B. VI, page 510. W. O. E.

Iron and ammonium citrate of commerce, its composition and behavior in certain solutions. G. J. W. FERREY. *Quart. J. Pharm.* 1, 351-62(1929).—The ppt. yielded by some samples of Fe and NH_4 citrate in soln. with MgSO_4 depends on the presence of Ca in these samples, probably as a result of the use of tap instead of distd. H_2O in the process of manuf. Some samples of the salt contg. Ca give no ppt. when dispensed with MgSO_4 , because of the high proportion of citric acid to NH_3 in such products. The samples yielding ppts. in simple aq. soln. contain free Fe^{III} ions which accordingly react with $\text{K}_3\text{Fe}(\text{CN})_6$. In some cases the ppts. are due to Fe^{III} in org. combination; in others the Fe appears to be in inorg. combination. Furthermore, samples contg. a low % of NH_3 , a comparatively large quantity of acid NH_4 ferrylcitrate may be present and be pptd. as a green solid in the presence of large concns. of true Fe and NH_4 citrate.

Some conditions during manuf. in which free Fe^{III} ions and acid ferrylcitrate may be formed are indicated in the present study. It is shown that many perfectly satisfactory preps. of Fe and NH_4 citrate may contain less than 5.5% of NH_3 , and that the 6.9% recommended by Todd as a min. is therefore too high. It is recommended that the B. P. assay for Fe should be altered to include washing and re-ignition of the ash, and that in this case the limits for residue on ignition should be 30 to 32%, instead of 31 to 32%, as in the present B. P. Also in *Chemist. and Druggist* 109, 121-5; *Pharm. J.* 121, 87-8(1928). W. O. E.

Melting point of cocaine hydrochloride. WILFRED SMITH. *Quart. J. Pharm.* 1, 387-8(1929).—While the m. p. of cocaine-HCl varies with the rate of heating, the m. p. as given in the various pharmacopeias is evidently too low for the salt as prepd. at the present time. It is suggested that the m. p. be taken by introducing the salt into a bath previously heated to 195° , when the m. p. shall not be below 197° . Also in *Chemist and Druggist* 109, 125-6; *Pharm. J.* 121, 88(1928). W. O. E.

Apiol. J. R. WALMSLEY. *Quart. J. Pharm.* 1, 388-94(1929).—The liquid green apiol met with in trade does not agree with the description given in the monograph in the B. P. C. It has been shown that an ethereal ext. of parsley seed is a fatty oil contg. a small proportion of non-fatty matter, and therefore cannot possess the d or the soly. ascribed to it by the B. P. C. Other solvents except alc. yield exts. which have similar properties to the Et_2O ext. The fatty oil contains glycerides of an unsatd acid peculiar to the Umbelliferae. The non-fatty matter is chiefly phenol ethers which have been shown to be myristicin, and not apiol, in the English and French grown fruits. The non-fatty matter of the American grown seed requires further study. The growing of a variety of parsley (*Carum petroselinum* B and H; *Petroselinum sativum* Hoffman; *Apium petroselinum* L) which will yield apiol, as is stated to be the case with German grown fruit, is a matter which should be taken up by proper authorities, especially as myristicin is stated to be toxic. The use of alc. as a menstruum appears to have advantages, and will be further studied. The terms apiol and liquid apiol are inaccurate when applied to the ethereal ext.; Oleo-resin Petroselinum (or Oleo-resin Apii) is more suitable and should be used in the B. P. C. in place of apiol. The only substance to which the name apiol can be correctly applied is the cryst. stearoptene, formerly official in the French Codex. The essential oil of parsley then appears to be the only substance worthy of the name liquid apiol, and only if obtained from an apiol-bearing variety of parsley. Also in *Chemist and Druggist* 109, 127-9; *Pharm. J.* 121, 89-90(1928). W. O. E.

Infusion of senega. J. F. LIVERSEGE. *Quart. J. Pharm.* 1, 394-9(1929).—Infusion of senega as actually dispensed, as also concd. infusions, showed great variations in compn. Senega roots and infusions prepd. from them show much less variation. It is desirable that the new B. P. should give a formula for 1-8 concd. infusion of senega to be dild. as required, and the product to take the name of "Infusum Senegae" and the name of the present prepn. altered to "Infusum Senegae Recens." Other infusions in common use should be treated similarly. Also in *Pharm. J.* 121, 90-1; *Chemist and Druggist* 109, 129-30(1928). W. O. E.

Malt extract and oil emulsions. I. Composition of commercial malt extract and cod-liver oil emulsions. J. M. JONES AND T. McLACHLAN. *Quart. J. Pharm.* 1, 400-1(1929).—Twelve emulsions of malt ext. and cod-liver oil obtained from various sources have been examd. and the results obtained tabulated. While the majority of the samples contain an adequate proportion of cod-liver oil, it is shown that in the case of 1 sample it is necessary to take 5 fl. oz. of emulsion to obtain a dose of a fl. dr. of cod-liver oil. The methods followed in the investigation are indicated. **II. Vitamin A content of commercial malt extract and cod-liver oil emulsions.** J. M. JONES. *Ibid* 401-2.—In order to avoid the use of a system of units different from the U. S. P. biol. units, which have come into general use, a factor has been employed to convert the no. of blue tintometer (Lovibond) units into values approx. corresponding to U. S. P. biol. units per g. By comparing a no. of samples on which biol. and colorimetric tests have been carried out it has been found that the av. value of this factor is 85. On this system a Norwegian cod-liver oil of good medicinal quality contains on the av. about 500 units of vitamin A per g. The cod-liver oil extd. from a 23-yr.-old emulsion gave a color test of about 250 units, showing that these emulsions retain their vitamin A activity for considerable periods. **III. Note on testing malt extract and cod-liver oil emulsions for vitamin A.** J. M. JONES AND NORMAN EVERS. *Ibid* 402-5.—In the course of the work indicated in the previous abstract, it was considered advisable to det. what loss, if any, of vitamin A occurred in the ordinary methods of extn. of cod-liver oil as used in analysis and incidental manipulations (exposure to light, desiccants, etc.). The

results obtained in these expts. are in some cases conflicting, and further work is evidently required, but there is clear evidence that the use of CaCl_2 for drying solns. of oils which are to be tested for vitamin A should be avoided. There is also sufficient evidence to show that such solns. should be kept as far as possible in the dark. It is clear, too, that further study is needed on the mode of action of CaCl_2 . Light certainly appears to accelerate the loss. Further work is contemplated with other drying agents. Also in *Chemist and Druggist* 109, 130-2; *Pharm. J.* 121, 91-2(1928). W. O. E.

Total alkaloids of *Datura fastuosa* Linnaeus and *Datura alba* Nees from the Philippines. JOAQUIN M. MARAÑON. Univ. of the Philippines and Bureau of Science, Manila. *Philippine J. Sci.* 37, 251-61(1928).—Leaves of *D. fastuosa* contain slightly more alkaloids than those of *D. alba*. In both, young leaves have more alkaloid than either the full-grown or senescent leaves. The same is true of the flowers and seeds, except in the seeds of the very young *D. fastuosa*. The pericarp of the very young fruit has more alkaloid than that of other stages of the fruit, a condition the reverse of that found in the seed. The pericarp of *D. fastuosa* yields more alkaloid than that of *D. alba*. The fruit *D. fastuosa* has more total alkaloid than fruit of *D. alba*. In both, very young and mature fruit contain more alkaloid than the nearly mature fruits. There is only a slight diff. in total alkaloid in stems of *D. fastuosa* and *D. alba*, but the root of *D. fastuosa* contains more alkaloid than that of *D. alba*. S. L. B. ETHERTON

New remedial agents. The ureide hypnotics. ANON. *Am. J. Pharm.* 100, 692-7(1928).—A review and discussion including a study of the claims for a no. of new cyclic ureides from the point of view of their chem. constitution. The following list of the principal cyclic ureides at present in use are discussed. Diethylbarbituric acid ("veronal"; "barbitone"), diallylbarbituric acid ("dial"), dipropylbarbituric acid ("proponal"), phenylethylbarbituric acid ("luminal"), butylethylbarbituric acid ("sonervel"; "neonal"), isobutylallylbarbituric acid ("sandoptal"), allylisopropylbarbituric acid ("allonal") (combination with amidopyrine), ethylisopropylbarbituric acid ("ipral") (calcium salt), cyclohexenylethylbarbituric acid ("phanodorm"), isoamylethylbarbituric acid ("amytal"), isobutylbromopropenylbarbituric acid ("noctal"). W. G. G.

Novonal, a new hypnotic. BOCKMÜHL AND SCHAUMANN. *Deut. med. Wochschr.* 54, 270-1(1928).—A description of the properties of novonal, a com. prepn. of diethylallylacetamide, $\text{Et}_2(\text{C}_6\text{H}_5)\text{CCONH}_2$. ARTHUR GROLLMAN

Instability of precipitin anti-sera in the tropics. HERBERT S. SHREWSBURY. *Analyst* 54, 20(1929).—A study of the literature indicates that anti-sera are unstable compds. produced at the blood temp., which are always tending to revert to their original mol. constitutions. Possibly anti-sera made from the blood of a bird would be more stable than that from a mammal. W. T. H.

New way to detect quinine valerate. STEPHEN SOULE. *Chemist-Analyst* 18, 11(1929).—Bruising the crystals in a glass mortar produces a marked fluorescence which persists until all the crystals have been reduced to fine powder. The fluorescence is very marked in the dark and is noticeable on a dark day. W. T. H.

Combinations of medicaments as an example of organic molecular compounds. P. PICHTER AND R. SEYDEL. Univ. of Bonn. *Z. physik. Chem.* 137, 107-25(1928).—P and R. investigate the freezing-pt. curves of 16 mixtures of compds. used in pharmacy with a view to finding relations between their pharmacological properties and their melting characteristics: antipyrine + orthoform-new, mol. compd. (1:1), m. 92°; pyramidone + orthoform-new; acetyl-aminoantipyrine + orthoform-new; antipyrine + *o*-aminophenol; antipyrine + Me *p*-hydroxybenzoate; pyramidone + *o*-aminophenol; pyramidone + Me *p*-hydroxybenzoate; antipyrine + Me *m*-aminobenzoate; antipyrine + Me *p*-aminobenzoate; pyramidone + Me *m*-aminobenzoate; pyramidone + Me *p*-aminobenzoate; sarcosine anhydride + orthoform-new; mol. compd. (1:1), m. 146°, sarcosine anhydride + Me *p*-hydroxybenzoate, mol. compd. (1:2), m. 99°; sarcosine anhydride + *o*-aminophenol, mol. compd. (1:1), m. 101°; sarcosine anhydride + Me *n*-aminobenzoate, mol. compd. (1:2), m. 62.4°; antipyrine + luminal.

ALBERT L. HENNE

Evaluation of preparations of the posterior lobe of the hypophysis by means of the in situ cat uterus. KONRAD SCHÜBEL AND WALTER GRILLEN. Inst. Erlangen. *Arch. expil. Path. Pharm.* 132, 145-71(1928).—The error in the method described amounted to about 15%. G. H. S.

Digitalis evaluation with the frog heart sinus. G. MANSFELD AND Z. HORN. Univ. Pecs. *Arch. expil. Path. Pharm.* 132, 257-76(1928).—The method is described and the character of the results obtained tabulated. G. H. S.

The British pharmaceutical and medicinal chemical industry. Wide range of production. H. A. D. JOWETT. *Times Trade and Eng. Supplement* (London) 23,

38(1928).—In addn. to well-known compds., briefly reviewed, neostam, an Sb compd. for treatment of kala-azar, avenyl, an org. deriv. of Hg for treatment of syphilitic lepers, and stabilarsan, an improved form of arsphenamine, are now being produced.

E. M. SYMMES

Perfumery chemicals and flavorings. The British industry. A. BOAKE, ROBERTS, AND CO. *Times Trade Eng. Supplement* (London) 23, 44(1928). E. M. SYMMES

Constituents of Chinese drug, "Ma Huang." VI. W. N. NAGAI AND S. KANAO. *J. Pharm. Soc. Japan* 48, 845-51(1928).—N.'s previous work on the constituents of "Ma Huang" showed that *Ephedra helvetica* (I) grown in China contained only *l*-ephedrine (II) and not *d*-isoeephedrine (or *d*- ψ -ephedrine) (III), which is the chief constituent of the plant grown in Europe. Recent investigation, however, showed that even the native Chinese plant contains a small amt. of III. This fact prompted N. and K. to study more thoroughly all the basic constituents in I. As a result 3 other bases were isolated from the plant grown in Pechili district. These are: *l*-methylephedrine (IV), m. 87-7.5, $[\alpha]_D^{20}$ -29.02°; HCl salt, m. 182°, $[\alpha]_D^{20}$ -29.87°; oxalate, m. 187°; picrate, m. 142°; chloroaurate, m. 128-9°. *d*-Methylisoeephedrine (V), m. 28°, b₂₁ 145-5.5°, $[\alpha]_D^{21}$ 48.13 (MeOH); HCl salt, $[\alpha]_D^{23}$ 58.11; chloroaurate, m. 126-7°. *Nor-d*-isoeephedrine (β -phenyl- β -hydroxyisopropylamine) (VI), m. 77.5-8°, $[\alpha]_D^{24}$ 32.69 (abs. alc.); H₂SO₄ salt, m. 290-1°, $[\alpha]_D^{27}$ 39.66; HCl salt, m. 180-1°, $[\alpha]_D^{24}$ 42.1°; oxalate, m. 235°; *l*-bitartrate, m. 202°. The method of isolation is described in detail. IV and V are stereoisomers and identical with compds. obtained by the methylation of II and *d*-isoeephedrine, respectively. Of 18 possible isomers of II, all of which have already been synthesized by N. and K. (*J. Tokyo Chem. Soc.* 32, 426; 36, 424; K.'s Dissertation, Tokyo Imp Univ. 1919) only 5 have thus far been found in nature.

NAO UEI

Imidazoledicarboxylic acid and its 2-methyl derivative as reagents for alkaloids. Y. TAMAMUSHI. Tokyo Imp. Univ. *J. Pharm. Soc. Japan* 48, 863-8(1928).—According to Pauly and Ludwig (*C. A.* 16, 4210), imidazoledicarboxylic acid (I) gives crystalline salts with certain bases which are relatively insol. in H₂O and have characteristic soly. and sharp m. p. so that these salts can be used for isolation and estn. of the bases from the mixt. T. has studied the salts of I and of 2-methylimidazoledicarboxylic acid (II) formed with 42 different bases and found that contrary to the statement of P. and L. salts of I with NH₃, MeNH₂, EtNH₂, Et₂NH and imidazole are sol. in H₂O and further that except for 3 compds., *i. e.*, Et₂NH-salt (m. 177-8°) and C₆H₅Me₂N salt (m. 215°) of I and C₆H₅Me₂N salt of II (m. 205°), all other salts had no sharp m. p. The NH₃ salt of I decompd. 280° and EtNH₂ salt decompd. 262° instead of 275° and 253-4°, resp., as given by P. and L. Conclusion: The compds. I and II can be used to a certain degree for detection of some bases, but they are worthless for their estn.

NAO UEI

"Zyozan" or Chinese drug "Ch'ang shan." K. KIMURA, M. NAKAO AND G. SHIMADA. Tokyo Imp. Univ. *J. Pharm. Soc. Japan* 48, 884-904(1928).—A review of literature and of geographical distribution as well as the anatomical study of the plant is given in detail.

NAO UEI

Compound tincture of benzoin. T. T. COCKING. *Chemist and Druggist* 109, 118-9; *Pharm. J.* 121, 86(1928); *Quart. J. Pharm.* 1, 337-46(1928).—Detn. of total solids alone in compd. tincture of benzoin (A) is not a true guide in judging its medicinal value. The quantities of alc.-sol. matters of its ingredients are given: Aloes, 81.1%; balsam of tolu, 92.0% (min.); benzoin, 65%; prepd. storax 95% (Brit. Pharm.). On this basis C. calcs. a standard of 18.165% for the total solids in A. Different authors have adopted standards varying from 15.85 to 18.0%. Com. samples (from British Drug Houses) showed 17.0-19.6%, others 17.3-21.8% when C.'s method was used: Evap. 5 cc. of A and dry *in vacuo* over H₂SO₄ at ordinary temp. to const. wt., *i. e.*, for about 48 hrs. The results by this method are 1.94% (av.) higher than those obtained by evapg. the tincture and drying at 100°. A complete scheme of analysis should consist of the detn. of (1) total solids, (2) acid no., (3) ester no., (4) sapon. no., (5) free balsamic acid, (6) total, (7) combined balsamic acids, (8) the ratio acid no. : ester no., (9) the ratio free : combined balsamic acids. (Cf. *C. A.* 12, 2229; 13, 162.) The results of a great no. of such detns., with max. and min. values, together with standards calcd. from the analytical data of the drugs are tabulated and discussed. Some striking differences are noted: The ratio (8) showed by calcn. 0.81-1.90, but the com. tinctures gave results far below the calcd. min. Likewise the acid nos. (based on total solids) were far below the calcd. nos., a fact not easily explained because the low value does not correspond to any decrease in balsamic acids. A value of total solids over 20% is regarded with suspicion.

S. WALDBOTT

Testing of barium sulfate for x-ray purposes. T. TUSTING COCKING. *Pharm. J.* 121, 86-7; *Chemist and Druggist* 109, 119-21 (1928); *Quart. J. Pharm.* 1, 363-72 (1928); cf. Bodsworth, *C. A.* 22, 2240.—A critical comparison is made of the tests given in the Brit. Pharm. Codex 1923, the U. S. P. X., and the German Pharm. with the tests recommended by B. and those of the British Drug Houses. The latter tests are put forward as tentative standards. To test for *sol. Ba salts* and for *acid-sol. matter*, boil 10 g. BaSO_4 with 100 cc. of 10% AcOH for 10 mins. and filter. Evap. 50 cc. of the clear filtrate to dryness and weigh the residue. Digest this with 20 cc. H_2O and filter. To the clear filtrate add 1 cc. dil. H_2SO_4 ; no turbidity or ppt. should be produced upon standing for 1 hr. The test for *sulfide* relies on the color produced by H_2S gas evolved on treating BaSO_4 with dil. HCl , upon dry $\text{Pb}(\text{AcO})_2$ paper contained in a tube 5 mm. wide. The dry paper is more sensitive than filter paper moistened with the soln. To test for *As*, treat 10 g. BaSO_4 with 50 cc. hot H_2O , 10 cc. of stannated HCl (As test soln.) and 10 g. of granulated Zn in the Gutzeit app. (Brit. Pharm. 1914). The Pb paper should not be blackened more than that of a blank test (showing absence of *sulfide*, *sulfite* and *thiosulfate*), and the stain on the HgCl_2 paper should not indicate more than 1 p. p. m. of As_2O_3 . The test will detect 0.1 p. p. m. For *heavy metals*, add 50 cc. of clear, satd. H_2S - H_2O to the remaining portion of the test for sol. Ba salts. No darkening should occur. For *phosphate*, boil 2 g. BaSO_4 with 10 cc. of 50% HNO_3 , cool and filter. To the filtrate add 5 cc. NH_4 molybdate soln., allow to stand for 1 hr. in a warm place. No yellow ppt. should appear. For *neutrality*, mix 2 g. BaSO_4 with 5 cc. CO_2 -free distd. H_2O and add 2 drops of Universal Indicator (British Drug Houses). The color produced should indicate a pH of not less than 6.0 nor more than 8.0. This test is about 1000 times more delicate than the test with litmus paper.

S. WALDBOTT

Liquor arsenicalis, Brit. Pharm. W. A. KNIGHT. *Pharm. J.* 121, 396-7 (1928); cf. *C. A.* 23, 241.—**Liquor acidi arsenosi**, Brit. Pharm. Codex (A) recommended to replace Fowler's soln. (B), requires prolonged reflux boiling in its prepn. The use of B should be continued, except that a 10% colorless stock soln. of As_2O_3 in K_2CO_3 be made which keeps well, and B be prepd. only as needed by adding the required quantity of compd. tincture of lavender. Or the original Brit. Pharm. formula may be used, except that K_2CO_3 be replaced by the more stable KHCO_3 in 1% concn.; a 2% concn. (as in U. S. P.) renders the prepn. unnecessarily alk. A 1% concn. may be rendered slightly acid whenever desired, by adding 4% of dil. HCl ; this would take the place of A and of liquor arsenici hydrochloricus, Brit. Pharm.

S. WALDBOTT

Methylated iodine preparations. FRANK SLOMAN. *Pharm. J.* 121, 419 (1928); cf. *C. A.* 23, 481.—Development of the odor is completely obviated by addn. of CHCl_3 to the tincture (1:32 by vol.).

S. WALDBOTT

Chemistry, pharmacology and therapeutics of *Agave salmiana* (COLIN) 11H. Disinfectants and insecticides (RIDEAL, RIDEAL, SCIVER) 18. Development of CaCO_3 cells with particular reference to medicinal plants (BRUNZEMA) 11D. *Oenanthe sumnifera* (GOODRICH, LYNN) 11D. Azo compounds (Fr. pat. 643,446) 10. Colloidal dispersions (Brit. pat. 292,965) 13.

Therapeutic substances. RYK GULDENWERKE CHEMISCHE FABRIK A.-G. Ger. 469,788, June 18, 1925. A strong Ca -contg. soln. of theophylline for injection purposes is prepd. by bringing theophylline, ethylenediamine and salicylic acid, either singly or as compds. of reaction of one on another, into aq. soln., and adding CaCl_2 either at the same time or later.

Molded medicinal preparations. I. G. FARBENIND. A.-G. Brit. 293,090, March 25, 1927. Protargol or other medicaments are used with a carrier vehicle comprising gum tragacanth or like material rendered readily sol. in water by addn. of a hydro-tropic substance such as the Na salt of *p*-toluenesulfonic acid or the Na salt of sulfanilic acid. *Succus liquiritia* and other "indifferent" water-sol. substances such as borax or milk sugar may also be added.

Medicinal capsules of gelatin carrying markings in contrasting colors. KEITH K. KELLER. U. S. 1,701,811, Feb. 12. Markings such as the name of a medicine are imprinted, e. g., with colored wax.

Medicine from the radish. CHEMISCHE FABRIK VORM. SANDOZ. Brit. 292,984, June 28, 1927. A medicinal prepn. is obtained from the fresh roots or juices of the radish by a process similar to that applied to garlic as described in Brit. 235,883. A dry, odorless prepn. of radish and charcoal is obtained which may be administered as a powder or may be compressed into tablets.

Basic cinchona alkaloid salts of bile acids. FRITZ MÜLLER, ERNST BURCKHARDT and ERNST ROTHLIN (to Chemische Fabrik vorm. Sandoz). U. S. 1,701,138, Feb. 5. Salts of alkaloids such as quinine, quinidine or dihydrocupreine ethyl ether with bile acids such as cholic or desoxycholic acids form amorphous powders easily sol. in alc., MeOH and acetone but difficultly sol. in ether and water. They are suitable for combating blood parasites.

Optic-nerve and retina extract. ELMER H. STUART (to Eli Lilly & Co.). U. S. 1,700,691, Jan. 29. Optic nerves or retinas (or both) of animals such as hogs or cattle are repeatedly extd. with alc. and the combined exts. are evapd. and treated with water to obtain an aq. ext. which may be used as a preventive of, or remedy for diseases of the human optic nerve or retina.

Complex organic antimony compounds. HANS HAHN (to Winthrop Chemical Co.). U. S. 1,701,234, Feb. 5. In processes similar to those described in U. S. 1,628,838 (C. A. 21, 2170), by the substitution as starting materials of the neutral salts of carboxylic acids and sulfonic acids of such polyphenols as contain 2 OH groups in *o*-position to each other, such as gallic acid, gallo-carboxylic acid, pyrocatecholdisulfonic acid or 2,3-dihydroxynaphthalenedisulfonic acids, new products are obtained which are solids easily sol. in water and the aq. solns. of which are not irritating and may be sterilized at 100° and may be used as *trypanocides*. Examples are given of the production of derivs. from gallic acid and from pyrocatecholdisulfonic acid. Cf. C. A. 23, 1216.

Organic mercury compounds. CHINOIN GYÓGYSZER ÉS VEGYÉSZETI TERMÉKEK GYÁRA R. T. (Kereszty und Wolf). Austrian 111,579, July 15, 1928. Therapeutically valuable compds. contg. Hg are prepd. by treating an aliphatic or an aromatic acid anhydride, or an aromatic acid anhydride contg. an aliphatic side chain, with a compd. prepd. by the action of a Hg salt on $\text{CH}_2:\text{CHCH}_2\text{NH}_2$ or $\text{CH}_2:\text{CHCH}_2\text{OH}$. The examples describe the prepn. of products from (1) succinic anhydride and a reaction product of $\text{CH}_2:\text{CHCH}_2\text{OH}$ and $\text{Hg}(\text{OAc})_2$; (2) camphoric anhydride and a reaction product of $\text{CH}_2:\text{CHCH}_2\text{NH}_2$ and $\text{Hg}(\text{OAc})_2$; and (3) *o*-carboxyphenoxyacetic acid anhydride and a reaction product of $\text{CH}_2:\text{CHCH}_2\text{NH}_2$ and $\text{Hg}(\text{OAc})_2$.

Organo-mercury compounds. I. G. FARBENIND. A.-G. Brit. 292,245, March 16, 1927. An aq. soln. of a salt of an aromatic aminosulfonic acid is treated with a sol. Hg salt at ordinary temp. Examples are given of the treatment of Na sulfanilate, 2-aminophenol-4,6-disulfonate and 2-anisidine-4-sulfonate. The products are water-sol. and may be used as *disinfectants*; their soly. is increased by use of NaCl and for use in "combating pests" dextrin or other suitable substances may be added to them. 2-Aminophenol-4,6-disulfonic acid is made by sulfonating 2-aminophenol first with concd. H_2SO_4 and then with "oleum."

Organo-tellurium compounds. G. T. MORGAN and H. BURGESS. Brit. 292,222, March 14, 1927. A pentamethylene α,ϵ -dihalide is treated with a metallic telluride such as that of Al, Mg or alkali or alk. earth metals, suitably in the presence of an anhydrous solvent. By heating or by elimination of halogen with reducing agents, the products may be converted into cyclotelluropentane and from the latter, by treatment with halogen or H_2O_2 , the dihalide or dioxide may be formed. The products possess *germicidal properties* and may be used as *therapeutic agents*. Several examples are given, among which are the production of cyclotelluripentane 1,1-dibromide, 1- ϵ -bromopentamethylenecyclotelluripentane 1-bromide, pentamethylene- α,ϵ -biscyclotelluripentane 1-bromide, cyclotelluropentane, cyclotelluripentane 1,1-dioxide, pentamethylene- α,ϵ -biscyclotelluripentane 1-perbromide and dichromates form 1- ϵ -chloropentamethylenecyclotelluripentane 1-chloride and pentamethylene- α,ϵ -biscyclotelluripentane 1-chloride or cyclotelluripentane 1,1-dichloride.

Carbamidoarylarsonic acids and their inner anhydrides. R. W. E. STICKINGS and May & BAKER, LTD. Brit. 293,152, May 3, 1927. Aminoarylarsonic acids and their substitution products are condensed with a cyanogen halide in an aq. medium. Examples are given of the prepn. of phenylurea-*p*-arsonic acid, the inner anhydride of 2-hydroxyphenylurea-5-arsonic acid and the inner anhydride of 2-carboxyphenylurea-5-arsonic acid. The products may be used as *therapeutic agents*.

Essential oils. AKTIEN-GESELLSCHAFT FÜR KOHLENSÄURE-INDUSTRIE and E. B. AUERBACH (to Vianova Ges. für chemische Industrie). Brit. 292,982, June 28, 1927. Essential oils and other odorous substances are extd. from plant material such as cloves, caraway seeds or iris root by use of liquid CO_2 , which is evapd. from the ext. obtained and liquefied for further use.

Hormones. S. FRANKEL (to Société anon. pour l'industrie chimique à Bâle). Brit. 292,962, June 27, 1927. Exts. of female internal-secretory organs are freed from phosphatides, cholesterol, cholesterol esters and fats, and then treated with an agent

such as a heavy-metal acetate or alk. earth acetate, which will form soaps insol. in the solvent used. The soaps and excess of the metal salt are removed, and the hormone thus obtained is crystd. at a very low temp. from a suitable org. solvent or is converted into its dibromide and finally debrominated. Various details and modifications are described. Cf. *C. A.* 23, 242.

Ethyl chloride tube. H. A. MÜLLER. Brit. 292,966, June 28, 1927. Structural features.

Perfumes. I. G. FARBENIND. A.-G. Fr. 643,352, Nov. 4, 1927. Ionones, methyl-ionones and other perfumes such as geraniol have their color cleared and their odor improved by hydrogenation with H in the presence of a Ni catalyst, with EtONa, an amalgam of Al, Zn dust, etc.

Perfumes from flowers, etc. I. G. FARBENIND. A.-G. Brit. 292,667, March 21, 1927. In extg. perfumes in active material as described in Brit. 255,346 (*C. A.* 21, 2760) the process of extg. the perfume from the active material with a solvent and the subsequent sepn. of the perfume from the solvent are effected at a temp. below 30°. Solvents may be used, such as EtCl, which do not dissolve in water, or which absorb water to a small extent only. Brit. 292,668 relates to preliminary drying of the air or other gas, in similar processes and regulating of the velocity of the gas stream.

Coloring material for cosmetics. JULIUS CULMANN and EDGAR AHRENS (to G. Siegle Corp. of America). U. S. 1,702,227, Feb. 12. Al lakes of red dyes are used, such as may be produced by pptn. from a water-sol. halogen deriv. of fluorescein with a sol. Al salt in the presence of Na benzoate.

Tobacco substitute. FRANK K. CHISHOLM. Ger. 469,789, Dec. 11, 1926. See U. S. 1,680,860 (*C. A.* 22, 3737).

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

The chemical and allied industries. II. The acids, alkalies, and salts. REX FERNES. *Chemistry & Industry* 48, 3-6(1929); cf. *C. A.* 22, 3469. E. H.

Storing, distributing and using hydrochloric acid in the plant. SIDNEY SCHEIN. *Am. Met. Eng.* 35, 673-6(1928). E. M. S.

Fausser process of nitric acid manufacture. JAROSLAV MILBAUER. *Chem. Obzor* 328, 30(1928).—Description of the Fausser process which consists of oxidation of NH_3 to HNO_2 and the use of a Pt catalyst and air under 5 atm. pressure, whereby the yield decreased from 91.6% to 91.2%, the time of contact from 1.8×10^{-4} to 2.2×10^{-4} and the amt. of HNO_3 increased from 2.76 to 12.8 kg. per g. of Pt. JAROSLAV KUČERA

Sulfuric acid. Recent developments. A. GROUNDS. *Times Trade and Eng. Supplement* (London) 23, 24(1928).—By a special circular Dwight-Lloyd sinterer working on Zn ores (illustrated) 80% of the gas will contain 6% SO_2 , useful for H_2SO_4 manuf., and 20% gas will contain 0.2% SO_2 , which is discarded. The best use of the Schmiedel box is in the following order: Glover tower, Schmiedel box, a tower, a second Schmiedel box, a second tower, a Gay-Lussac tower. By the Schmiedel-Klencke system 28% acid can be produced directly without concn. Statistics of the use of pyrite vs. Sare given. Synthetic NH_3 will stimulate the use of CaSO_4 in $(\text{NH}_4)_2\text{SO}_4$ manuf. The Lauenroth dec. furnace treatment of phosphate rock to give P and its acids, then NH_3 phosphate, will reduce H_2SO_4 consumption in fertilizers. Synthetic NH_3 and HNO_3 eliminate H_2SO_4 and NaNO_2 . E. M. SYMMES

Contact process for the manufacture of sulfuric acid from zinc blende roaster gases. S. ROBSON. *Trans. Can. Inst. Mining and Met.* 30, 950-81(1927).—The roaster gases obtained from Zn ores contg. more than 2% Pb carry a large quantity of PbSO_4 fumes as well as As and other impurities. These are removed in modern plants by passing the gases through a series of baffled dust-settling chambers, thence through Glover towers and cooling pipes to an electrostatic separator, from which they are passed through coke filters, and washing and drying towers to the contact plant. For efficient working of the electrostatic separators the temp. of the gases should not exceed 500° and the velocity must not be greater than 1 ft. per sec. Numerous modern types of washing, drying and purifying towers are illustrated diagrammatically, and brief notes of their method of working and efficiencies with various impurities are given. The conversion is effected in two vessels, each of which is provided with a heat-interchanger. The first converter operates at a higher temp. (e. g., 530°) than the second, and converts the greater part of the SO_2 into SO_3 at a rapid rate; the second converter, serving to effect complete conversion, is required only in districts in which SO_2 discharged into the

atm. will affect surrounding industries. MgSO_4 is the most suitable catalyst support for high temps. and asbestos for the lower temps. B. C. A.

Spent oxide as material for the manufacture of sulfuric acid by the chamber process. W. HENRY IBBOTSON. *Ind. Chemist* 4, 513-21(1928).—The relative advantages and disadvantages of spent oxide and S are discussed. The compn. of spent oxide, conditions affecting its value for H_2SO_4 manuf., difficulties surrounding its use, and methods of burning are given in detail. Modern types of burners (H. H. burner, Harris, Carmichael, Bracq-Laurent and Kershaw) are described with several drawings and their operation is dealt with. Testing of spent oxide is given in detail; and its weathering and storage are described briefly. Several patented methods of recovering S, cyanides and NH_3 from spent oxide are covered briefly. E. G. R. ARDAGH

Liquid sulfur dioxide, its manufacture, transportation and uses. CHARLES W. JOHNSTON. *Chem. Markets* 23, 476-9(1928); cf. C. A. 22, 2800. E. M. S.

Acidproof lining for containers. H. E. SCHUBERT. *Bauing* 9, 327(1928); *Building Sci. Abstracts* 1, 180.—A method of rendering containers proof against concd. acids is described. The internal surface is lined with proprietary slabs made of an artificial asphalt laid in cement. These slabs are not as brittle as ceramic tiles, and are odorless, but melt at about 115° . The joints are closed with a mortar made from the same material as the slabs. Reference is made to a compn. which may be applied to wood, cement and iron. H. G.

The synthesis of ammonia. Agriculture's debt to Germany. J. BUER. *Times Trade and Eng. Supplement* (London) 23, 47(1928). E. M. SYMMES

The manufacture of synthetic ammonia by Mont-Cenis process. RUDOLPH BATTIG. Mont-Cenis Process, Westphalia. *Mining J.* 164, 22-3, 39-40(1929).—H from coke-oven gas (45-55% H) is used for the production of synthetic NH_3 after purification by the Linde process. The process operates at 400° and under 100 atm. pressure. Even though the temp. and pressure are lower than customary, the yield is just as high because of the catalyst employed. The life of the catalyst is high (8 months at least). Highly uniform temp. is possible through heat interchangers within the furnace. Costs of repairs and gas losses are low. The world N consumption is reviewed. Fundamental requirements for N fixation are discussed. The value of coal at the mine is compared with its value after processing. ALDEN H. EMERY

Synthetic ammonia plant at Ostend. F. A. F. PALLEMAERTS. Union Chimique Belge, Brussels, Belgium. *Ind. Eng. Chem.* 21, 22-9(1929).—Illustrated, detailed description of an exptl. plant at Ostend, combining the Linde system of coke oven gas fractionation and the Casale synthetic NH_3 process. The rated capacity is 16 tons NH_3 per day, from installed equipment of three 8-ton units. The regular av. output is 50% above the 16-ton rating. The published NH_3 cost is 9 cents per kg. N in the form of $(\text{NH}_4)_2\text{SO}_4$, including the cost of H_2SO_4 , total operation costs, amortization, etc. The H cost is reported as \$0.1883 per 1000 cu. ft. New methods of coke-oven gas purification before liquefaction, such as C_6H_6 removal by refrigeration and pressure water washing, are given, as well as recent improvements in the Casale synthesis system, such as replacement of the circulating pump by an injector system and compressor feed direct from the liquefaction equipment at 9 atm. The $(\text{NH}_4)_2\text{SO}_4$ plant uses a 9 ft. diam. saturator, which produces 100 tons per day. R. L. DODGE

Barite and barium products in 1927. R. M. SANTMYERS. *Bur. Mines, Mineral Resources of the U. S.* 1927, Pt. II, 247-56 (preprint No. 22 published January, 15, 1929) E. J. C.

Titanium salts and pigments. Principal outlets. ANON. *Times Trade and Eng. Supplement* (London) 23, 33(1928).—A review of the main processes. Much interest is now being shown in the Monk-Irwin process involving hitherto unused Canadian ores. E. M. SYMMES

Silicate of soda. Production and applications. ANON. *Times Trade and Eng. Supplement* (London) 23, 25(1928).—A drawing of an approved dissolver is shown. E. M. SYMMES

Fundamental considerations and results of the efforts to open up new sources of potash. G. WAGNER. *Kali* 22, 175-8, 198-201, 223-5, 238-43, 253-6, 267-72, 287-90, 293-300(1928).—Algae and minerals, analyses of which are given, are studied as sources of potash. Difficulties of transport, labor, sanitation, etc., in the production of potash and bromine from the Dead Sea, as well as of potash from mineral deposits in various countries, are considered. PAUL J. CULHANE

The Backman system of making chloride of lime mechanically. GÖSTA ANGEL. *Chem.-Ztg.* 52, 962-4(1928).—A series of superimposed chambers, as in a mech. roaster, is built of reinforced concrete, carefully protected by the use of asphaltum cements.

Slowly revolving arms with plows gradually work the lime from the top to the bottom and mech. conveyors carry the finished chloride of lime to discharging bins. At the same time dry Cl is admitted to the 2nd or 3rd levels, and as it passes up through the remaining floors (there are usually 8 levels) it is absorbed. Cooling coils in the various chambers help in keeping the temp. down; it should not rise above 50° , and a max. of $35-40^{\circ}$ is recommended. Dry, cool air is blown into the upper part of the chloride of lime bins to keep down the temp. and to carry out free Cl from the finished product. Hydrated lime, with an excess of 0.5% H_2O , is made mechanically, stored at least 10 days to give it uniformity, and then fed into the chlorinating chambers in regulated amounts. Successful supervision of the process is dependent upon maintaining temps. nearly const. at desired places throughout the plant. If the CaO feed becomes too small in proportion to the Cl, the highest temp. appears on the 4th or 5th floors, and then chlorates form. Each chamber makes about 3.2-4 tons (metric) per 24 hrs., with a power consumption of 1.5 h.p. Construction costs are about like those for a lead-chamber plant. The chief advantages of the process are the uniformity of the product and the low labor cost. Damage to the neighborhood is practically absent in a well-managed plant.

W. C. EBAUGH

Lime in 1927. A. T. COONS. Bur. Mines, *Mineral Resources of the U. S. 1927*, Pt. II, 139-51 (preprint No. 15, published January 2, 1929).

The importance of hydrogen. Industrial production. A. M. HARKER. *Times Trade and Eng. Supplement* (London) 23, 26 (1928).—Electrolytic cells generating H under 200 atm. pressure are promising. Thermal decompn. of natural gas is not yet established. The Liljevoth process involving P and steam to give H requires large amounts of power and the H contains PH_3 . Liquefaction of coke-oven gas allows economical production of C_2H_4 , and after removal of H the gas remaining has a high calorific value.

E. M. SYMMES

Value of iodine. Extensive applications. E. L. GILL. *Times Trade and Eng. Supplement* (London) 23, 26 (1928).—I has a marked beneficial effect when fed to cattle, horses and fowls. I is also used successfully in Cu lixiviation from ores in Argentine. I aids in dyeing tussah silk and rayon. I is used in aphid sprays, seed and soil treatment, and $CaIO_2$ in small amounts is a food preservative, better than H_3BO_3 . I has been used to treat drinking water.

E. M. SYMMES

The fixed-nitrogen industry. J. F. CROWLEY. *Times Trade and Eng. Supplement* (London) 23, 27 (1928).—The Haber process is confined to large plants where it was installed when no other process was available. The Casale process is the most outstanding of the newer developments, now used in about 25 plants. The Fauser and Claude processes are next best established. The newer processes are more simple to operate and are possible on a small scale. In 1930-31 Chile nitrate will be about 14.25% of the fixed-N supplies. The cost of H is $\frac{3}{4}$ of the $(NH_4)_2SO_4$ cost. In the U. S. by-product NH_3 was 47.5% of the total consumption in 1926-7. This has so far delayed synthetic NH_3 development but demand is increasing so fast that by-product NH_3 can no longer fill the needs.

E. SCHERUBEL

Recent carbon dioxide fire-extinguishing plants. BRUNO MÜLLER. *Chem.-Ztg* 52, 966(1928).—The use of liquid CO_2 in extinguishers that permits it to be discharged in a liquid condition has proved to be of value in fire fighting aboard ships, in oil refineries and where the fire is raging in an enclosed space. For fires in the open CO_2 snow is preferred. CO_2 , like any other extinguishing agent, is not of universal application.

W. C. EBAUGH

Zn (Fr. pat. 643,483) 9.

Hydrocyanic acid. SYNTHETIC AMMONIA & NITRATES, LTD., and T. EWAN. *Brit.* 292,749, May 21, 1927. In a process involving passing vapors of formamide over a heated catalyst, the reaction gases are heated by internal heaters consisting of electrically heated gauzes (other than Fe or Ni or their alloys) such as brass or phosphor-bronze or a catalytic metal such as Cu which may be covered with a layer of refractory oxides.

Hydrocyanic acid. BADISCHE ANILIN- & SODA-FABRIK. *Fr.* 33,225, Mar. 25, 1927. Addn. to 606,843. HCN is produced by passing formamide, alone or mixed with NH_3 formate, in a dild. or rarefied state with rapidity over metallic catalysts such as Fe, Al, or V_2A -steel heated above 300° . NH_3 may be used as the dilg. gas.

Hydrofluoric acid. MAX BUCHNER (to Albert F. Meyerhofer). *U. S.* 1,701,225, Feb. 5. Impure fluorspar is treated with acid such as H_2SO_4 capable of forming a gas mixt. comprising HF and SiF_4 ; this mixt. is reacted on by a F compd. such as BaF_2 to form a complex fluoride and the latter is then treated (as by heating) to form a compd. for reaction on the gas mixt. and free HF. Various modifications of the process are described. Cf. *C. A.* 22, 1657.

Bottle for hydrofluoric acid, etc. ARTHUR W. WILKINSON and CLARENCE W. RINGEL (to Sterling Products Co.). *U. S.* 1,701,937; Feb. 12. Bottles with a body and neck of wax are reinforced by a cylinder of material such as paper.

Nitric acid. F. C. ZEISBERG (to E. I. du Pont de Nemours & Co.). Brit. 292,951, June 27, 1927. Vapors of dil. HNO_3 are passed into the foot of a dehydrating tower from a boiling vessel and a dehydrating agent such as strong H_2SO_4 is run into the top of the tower. Vapors of strong HNO_3 are condensed in a reflux from which part of the acid is returned to the tower and part led to storage. The app. is described.

Nitric acid from ammonia. H. PAULING. Brit. 292,830, Oct. 31, 1927. A uniform mixt. of NH_3 and air for the catalytic production of HNO_3 is obtained by absorbing the NH_3 in water and removing it by blowing air through the soln. An arrangement of app. is described.

Phosphoric acid and potash. WILLIAM H. WAGGAMAN and HENRY W. EASTERWOOD (to Victor Chemical Works). U. S. 1,701,286, Feb. 5. A briquetted mixt. of a finely ground natural phosphate, a K-bearing silicate, and coal, coke or other suitable carbonaceous material is heated to a smelting temp. of $1200\text{--}1600^\circ$ until substantially all the K, P and H_3PO_4 are driven off and the volatilized products are recovered.

Phosphorus pentoxide and phosphoric acid. GUSTAV PISTOR, HERMANN LANG and ROBERT SUCHY (to I. G. Farbenind. A.-G.). U. S. 1,700,708, Jan. 29. Yellow P is melted and passed through nozzles and the jets of P thus formed are burned. An app. is described.

Sulfuric acid. THE SELDEN COMPANY. Fr. 642,361, Sept. 30, 1927. In a contact app. for the production of H_2SO_4 , the SO_2 and air are led through heat exchangers at least partly immersed in the catalyst, the gases passing down a central tube, up a surrounding tube in direct contact with the catalyst and then down through the catalyst. Cf. C. A. 23, 486.

Ammonia synthesis. M. CASALE-SACCHI. Brit. 292,342, June 7, 1927. Mixts. of H and N for NH_3 synthesis are prepd. by fractionating liquid air to yield pure N and slightly impure O, using the O for prepg. H by incomplete combustion of hydrocarbons and mixing the N with the H thus obtained. In effecting the incomplete combustion of the hydrocarbons, the presence of steam serves to cause conversion of the CO formed into CO_2 and the water and CO_2 are sepd.

Ammonia synthesis. FREDRIK W. DE JAHN (to Atmospheric Nitrogen Corp.). U. S. 1,701,478, Feb. 5. Incoming gases are passed in heat-exchange relation to the hot gases of the reaction and then heated to substantially the temp. required for the reaction by passing the preheated gases through and in unrestricted thermal contact with the catalytic body and thence into direct contact with the catalytic body. An app. is described in which the gases just before coming into reactive contact with the catalytic body are passed through tubes extending through the catalytic mass. Cf. C. A. 23, 486.

Ammonia synthesis. SYNTHETIC AMMONIA & NITRATES, LTD., and J. HUGHES. Brit. 293,138, April 6, 1927. Inert gases such as CH_4 and A are prevented from accumulating in a circulating system by purging a part of the gas, scrubbing it under pressure with a solvent such as kerosene, and if desired then returning it to the system.

Heat-exchange arrangement for ammonia synthesis apparatus. SYNTHETIC AMMONIA & NITRATES, LTD. and F. H. BRAMWELL. Brit. 292,404, Oct. 27, 1927. In a modification of the arrangement described in Brit. 241,817 (C. A. 20, 3541) which comprises one or more spirals of a pair of coaxial tubes, the inner members of these tubes are replaced by tubes through which the gas flows in parallel.

Recovery of salts. FRITZ HORNUNG. Fr. 643,568, April 14, 1927. An app. for recovering salts such as KCl from solns. by cooling under vacuum comprises 2 or more inverted barometric vessels with their open ends in a tank and connected by a tube across which the soln. flows. The hot soln. enters at the side of the first vessel and the cooled soln. flows away at the side of the last, the salt settling into the tank separately.

Briquetting salt. MASCHINENFABRIK BUCKAU R. WOLF A.-G. Ger. 469,822, July 24, 1924. Salt is treated with superheated steam before pressing to briquets.

Ammonium salts. MONTECATINI SOC. GENERALE PER L'INDUSTRIA MINERARIA ED AGRICOLA. Brit. 292,129, June 14, 1927. An acid such as H_2SO_4 is sprayed into an atm. of NH_3 and the concn. of the acid is preferably such that the heat of the reaction vaporizes the water and leaves a dry salt. An app. is described.

Alkali sulfides. WOLF JOHANNES MÖLLER and FRIEDRICH KLEMA. Austrian 111,838, Aug. 15, 1928. The reaction temp. necessary for the reduction of alkali sulfates with carbonaceous reducing agents is reduced to below 850° by adding alkali sulfide to the mixt. The reaction may be effected in a rotary furnace with coke as the reducing agent, and the amt. of added sulfide may be such that the reaction proceeds at a temp. below the m. p. of the mixt. The added sulfide may be the crude product of a previous operation.

Cyanogen compounds. I. G. FARBENIND. A.-G. Fr. 643,039, Oct. 27, 1927. Cyanogen compds. are prep'd. from mixts. of CO and NH_3 , carbides of the Fe group being used as catalysts. Mo, Mn, W, Ce, Ti or Cu in the free state or combined may be added to the catalyst. An example is given in which a mixt. of CO and 10-12% NH_3 is passed over FeC and Mo at 450° , to form HCN.

Recovering cyanide from solutions. LOUIS D. MILLS and THOMAS B. CROWE (to Merrill Co.). U. S. 1,701,818, Feb. 12. Solns. such as those from ore treatment are acidified and air is passed in a closed circuit (in an app. which is described) first through the acidified soln. and then through an alkali soln. which is maintained in circulation.

Cyanamides. NICODEM CARO and ALBERT R. FRANK. Fr. 642,658, Oct. 21, 1927. Cyanamides of alk. earth metals and Mg are obtained by passing a current of HCN alone or mixed with neutral gases at temps. above 400° on to oxides or oxide-forming salts of these metals. Instead of HCN, gases forming it such as NH_3 and CO may be used, preferably between 650° and 850° . In examples, CaCO_3 is heated to 750 - 850° in a current of HCN. The product contains 99% CaCN_2 ; similarly 82.5% MgCN_2 is obtained from MgO. Cf. C. A. 23, 938.

Cyanamides. NICODEM CARO and ALBERT R. FRANK. Fr. 642,660, Oct. 21, 1927. NH_3 is caused to react on natural or artificial carbonates in the neighborhood of the dissocn. temp. of the said carbonates. A pressure of 3-10 atm. may be used.

Aluminum oxide. SVEN E. SIEURIN. U. S. 1,701,510, Feb. 12. Raw material such as bauxite is dissolved with HCl, followed by supersatn. of the AlCl_3 thus formed with HCl and calcination of the crystals of AlCl_3 obtained; the mother liquor remaining after pptn. of the crystals is conducted to the app. where the raw material is dissolved and thence back to the pptn. app. in such quantity and such manner that Al_2O_3 is brought to the pptg. app. at the same rate that it is removed to the calcining app., and that in the same time a quantity of the HCl vapors and steam corresponding to that obtainable from the calcination of the crystals is introduced into the pptn. app.

Concentrated ammonium nitrate solutions. CARLO TONIOLO. U. S. 1,700,911, Feb. 5. A hot dil. NH_4NO_3 soln. contg. added free HNO_3 is brought into contact with heated NH_3 gas contg. an inert gaseous diluent such as air in the presence of sufficient water to prevent formation of a dry product.

Ammonium sulfate. SOC. ANON. DES FOURS A COKE SEMET-SOLVAY ET PIETTE. Brit. 292,995, June 29, 1927. The process described in Brit. 262,320 (C. A. 21, 3716) is applied to the treatment of combustion gases from ovens or furnaces or other gases contg. CO_2 such as those from a Cowper stove. The gases are preliminarily passed through a dust remover and a cooler which lowers their temp. to about 25° .

Calcium arsenite. JEAN ALTWEGG and ANNE-MARIE DUTEL. U. S. 1,700,756, Feb. 5. A current of steam is passed over a dry mixt. of CaO and As_2O_3 .

Calcium nitrate. KARL BLUMRICH (to I. G. Farbenind. A.-G.). U. S. 1,700,116, Jan. 29. $\text{Ca}(\text{NO}_3)_2$ preps. in substantially dehydrated condition are mixed with solid powdery hydrate of $\text{Ca}(\text{NO}_3)_2$ at a temp. below the m. p. of the hydrate, in order to obtain a product which can be readily spread.

Crystallizing calcium nitrate. APPAREILS ET EVAPORATEURS KESTNER. Brit. 292,532, June 21, 1927. See Fr. 637,977 (C. A. 23, 245).

Lead carbonate. RENÉ DALOZE. Fr. 33,119, Mar. 10, 1927. Addn. to 632,020 PbCO_3 is obtained by a double decompn. between PbSO_4 and an excess of $(\text{AcO})_2\text{Ca}$ in soln. after incorporating in this soln. a quantity of neutral $(\text{AcO})_2\text{Pb}$ at least equal to the quantity of $(\text{AcO})_2\text{Pb}$ which will be formed by the reaction. The resulting soln. is treated with a base to transform the $(\text{AcO})_2\text{Pb}$ into dibasic acetate which is decompd. with CO_2 .

Potassium manganate. SOC. CHIMIQUE DES USINES DU RHÔNE. Brit. 292,991, June 29, 1927. MnO_2 is suspended in an excess of aq. melted potash contg. 60-85% KOH and heated to 160 - 200° and pure or dil. O is blown through the mass, which is also stirred. After the reaction, the excess potash may be removed with a limited quantity of water or dil. alk. soln. or by decantation of the fused mass.

Sodium chloride. GEORGE B. BURNHAM (to Burnham Chemical Co.). U. S. 1,701,295, Feb. 5. Searles Lake brine or other similar liquor contg. NaCl together with other salts is evapd. to effect supersatn. with NaCl and brought into contact with crystals of the supersatd. salt held in suspension in an upward flow of gradually decreasing velocity of the liquor so that the supersatd. salt in soln. is deposited upon the crystals; the size of the crystals is controlled by varying the initial upward velocity of the liquor in which the suspended crystals are held. An app. is described.

Neutral sodium phosphate. CHARLES F. BOOTH and ARTHUR B. GERBER (to

Federal Phosphorus Co.). U. S. 1,700,972, Feb. 5. In producing Na_3PO_4 contg. no free alkali, a Na_2HPO_4 substantially free of Na_2CO_3 is treated with NaOH until the resulting soln. has a relation of the phenolphthalein titration to the methyl orange titration of 0.432 to 0.451. U. S. 1,700,973 claims as a new compn., Na_3PO_4 , having no free alkali.

Sodium xanthate. WILHELM HIRSCHKIND. U. S. 1,701,264, Feb. 5. An alc. NaOH soln. and CS_2 are caused to react to produce and ppt. normally sol. Na xanthate and KOH is added to the mother liquor to ppt. a further quantity of the normally sol. xanthate.

Baryta. KARL EBERS. Fr. 643,154, Oct. 27, 1927. Baryta poor in chalk but preferably contg. SiO_2 and Fe and Mn compds. is roasted, slaked with water preferably without cooling, then with an acid, *e. g.*, HCl .

Hydrogen sulfide. RAYMOND F. BACON. U. S. 1,700,578, Jan. 29. Molten S and H are subjected to pressure to promote formation of H_2S by their reaction. An app. is described.

Hydrogen sulfide, etc. I. G. FARBENIND. A.-G. Brit. 292,186, Jan. 10, 1927. H_2S , "either free or in the form of mono-sulfide," is prepd. by heating under pressure, with H_2 , CO , formic acid or formates, S or inorg. compds. such as polysulfides or thiosulfides which yield free S on acidification. The reaction may be effected in the presence of water, NH_3 , solns. of alkali or alk. earth metal hydroxides, catalysts such as metals of the eighth group of the periodic system or their oxides, hydroxides, sulfides or carbonates or of substances such as silica gel, alumina or active C. Pressures up to 130 atm. and temps. below dull redness may be used.

Carbon disulfide. I. G. FARBENIND. A.-G. Brit. 291,382, May 31, 1927. An app. is specified for producing CS_2 by passing superheated S vapors over heated C, comprising a main reaction chamber and a superheating chamber formed side by side in a single casting of cast iron or steel. The superheating chamber is lined with material resistant to S and may contain filling material such as fragments of chamotte, porcelain Raschig rings or aluminous material such as bauxite.

Carbon disulfide and hydrogen or water gas. I. G. FARBENIND. A.-G. Brit. 293,172, May 26, 1927. CS_2 and H or gases contg. H are obtained by reaction, at temps. above 100° , between H_2S or sulfurous gases such as those obtained in the hydrogenation of S bearing coal or oils, and hydrocarbons such as CH_4 , natural gas, gases from cracking, distn. of coal or destructive hydrogenation of coal, tar or oils, etc. Catalysts may be used as Al_2O_3 , active C, silica gel, pumice or carborundum, and an elec. arc or an elec. heated C resistance may be used to effect the reaction. Air or CO_2 may be added if it is desired to produce water gas. Unchanged hydrocarbons may be further cracked or otherwise decomposed to obtain additional H.

Purification of hydrogen. SOC. L'AIR LIQUIDE (SOC. ANON. POUR L'ÉTUDE ET L'EXPLOITATION DES PROCÉDÉS GEORGES CLAUDE). Fr. 642,720, Mar. 25, 1927. See Brit. 287,577 (C. A. 23, 488).

Removing free chlorine or bromine from gases and liquids. BRITISH DYESTUFFS CORP., LTD., J. B. PAYMAN and H. A. PUGGOTT. Brit. 292,307, April 27, 1927. Solid hydrocarbons such as C_{10}H_8 , $\text{C}_{14}\text{H}_{10}$ or solid olefins which will form additive compds. with Cl and Br are used for removing these from gases or liquids such as HCl or HBr or their solns. or from cyanogen chloride or bromide.

Zeolites. ALPHONS O. JAEGER and JOHANN A. BERTSCH (Jaeger to The Selden Co.). U. S. 1,701,075, Feb. 5. Zeolites suitable for various catalytic purposes are prepd. contg. quadrivalent V in non-exchangeable form. Numerous details and examples are given.

Active carbon. A. B. RAY (to Carbide and Carbon Chemicals Corp.). Brit. 291,043, May 25, 1927. Non-coking coals of a bituminous or "sub-bituminous" character are impregnated with an aq. soln. of a carbonizing agent such as ZnCl_2 , H_3PO_4 , or K sulfide, dried by heating and then calcined at temps. above 600° , cooled, leached with water or dil. acid and dried, and may be further activated as by treatment under oxidizing conditions with superheated steam at 800 – 1000° . Coking coals and lignites also may be employed if they are suitably pretreated as by prolonged calcining under oxidizing conditions at 200 – 300° .

Active carbon. A. SCHREINER. Brit. 292,566, June 22, 1927. Wood, peat, lignite, material of spent org. liquors and the like are treated with solns. of alkali or alk. earth metal salts of thiocyanic acid or with $\text{K}_4\text{FeC}_6\text{N}_6$, the impregnated material is dried and distd. at 300 – 350° and is then heated in the absence of air to bright redness for half an hr. and after cooling is leached with water or HCl . The raw carbonaceous material may be first distd. and then impregnated and further heated in the absence of air.

Decolorizing carbon. EDOUARD URBAIN (to Urbain Corp.). U. S. 1,700,342, Jan. 29. Decolorizing C and a liquid such as H_2O , oils or hydrocarbons are thoroughly mixed together by grinding to form a paste which may be used in *wine making* or for other purposes.

Active or decolorizing carbon. J. VAN LOON. Brit. 292,213, March 10, 1927. Carbonaceous material such as wood charcoal, anthracite or bituminous coal and used or unused decolorizing or active carbons are ground in the presence of a wetting agent such as water or benzene heated (suitably under pressure and at $150-180^\circ$ for 10 hrs with steel balls) and the carbon is sepd. A solvent may be used which will remove tarry and other impurities.

Apparatus for manufacture of substantially pure carbon by decomposition of carbon disulfide. ANTON LEDERER. U. S. 1,700,942, Feb. 5.

Carbonaceous product from electric furnace treatment of carbonized lignin residues. JOHN J. NAUGLE. U. S. 1,701,272, Feb. 5. A product having an ash content of not more than about 3% is obtained by heat treatment of carbonized residues of soda pulp liquor or the like. The product is suitable for *treating sugar solns.*, etc.

Filtering material. HENRY BLUMENBERG, JR. U. S. 1,702,104, Feb. 12. A material suitable for filtering hydrocarbon oils, water or sewage comprises cellular material such as diatomaceous earth together with Ca hypochlorite and a small proportion of Na_2CO_3 .

Adsorbents for water vapor. THE SILICA GEL CORPORATION. Fr. 641,694, Sept. 30, 1927. An adsorbent for water vapor comprises a solid porous gel capable of adsorbing at least 10% of its wt. of water at 30° and 22 mm. partial pressure, impregnated with a dehydrating agent such as H_2SO_4 , $CuSO_4$ or metaphosphoric acid. The gel is preferably SiO_2 but may be oxides of metals such as W, Ti, Sn or Al. Cf. C. A. 23, 941.

Hardening casein, etc. I. G. FARBENIND. A.-G. Fr. 643,030, Oct. 26, 1927. Casein and other albuminous substances such as gliadin, zein, gelatin or ossein are hardened by means of glyoxal or a deriv. of a condensation product of glyoxal. By this means *insulating* and *glass-like* materials are obtained.

Drying casein. HERMANN A. AUDEMARS and LOUIS A. LALOY. Fr. 643,270, Nov. 2, 1927. In a continuous automatic drier for casein as in Fr. 626,978 the turbines are placed a distance from the entry of the drying cylinder to allow a preliminary drying of the casein and prevent sticking to the turbines.

Molding objects covered with a layer of cellulose. ROBERT A. L. WEITZEL. Fr. 642,886, Oct. 22, 1927. A layer composed of casein 1, Na sulforicinate $\frac{1}{2}$ and water 3 parts is interposed between the fatty substance and the layer of cellulose in the mold.

Urea condensation products. I. G. FARBENIND. A.-G. Fr. 643,104, Oct. 6, 1927. Urea is condensed with CH_3O in aq. soln. kept slightly acid (p_H 4 to 7), the water being then eliminated at a temp. below 50° , preferably *in vacuo*. The product is hardened by adding substances giving rise to acids on heating, and heating to a temp. between 50° and 100° . In examples (1) an aq. soln. contg. NaH_2PO_4 is used, the H-ion concn. being decreased before evapn. by the addn. of Na_2HPO_4 and Na_3PO_4 , and formamide is added before heating; (2) an aq. soln. of AcOH and AcONa is used, and $MgCl_2$ is added before heating. Cf. C. A. 23, 679.

Plastic material. MICHAEL J. HYNES. Can. 286,405, Jan. 15, 1929. Plastic material is made by mixing dextrin, water, pulp and calcined gypsum, thoroughly agitating and commingling the ingredients, and drying the mixt. It may be utilized by mixing with water and borax.

Objects from plastic substances such as rubber. AXEL T. GUSTAFSON. Ger. 470,270, Feb. 11, 1926. See U. S. 1,665,355 (C. A. 22, 1873).

Adhesives for use on clothing. WANDA STELKENS (née SCHWEGT). Ger. 470,149, Nov. 15, 1927. Worn places in clothing are coated, or patches stuck on, with a plastic soln. contg. rubber, and cellulose derivs. alone or mixed with condensation products and polymers of org. compds., such as the polymers of vinyl chloride.

Brake-band fabric. HEINRICH BORCHERS (in part to Rudolf Aldag). U. S. 1,700,759, Feb. 5. Material, such as asbestos threads, is impregnated with an adhesive such as mucilage or glue and comminuted grit-like roughening material such as fine sand is caused to adhere to the impregnated threads, the product is air-dried and is then woven into a textile fabric.

Impregnating brake linings, clutch facings, etc. RAYBESTOS Co. Brit. 292,371, July 20, 1927. The binder and fibrous base used are heated in a liquid (such as a bath of suitable molten metal) which does not react with nor dissolve the binder. An app. is described.

Coverings for walls, roofs, vehicles, tanks, etc. METALLBANK UND METALLURGISCHES GHS. A.-G. Brit. 292,621, June 23, 1927. Cu sheets supplied in rolls (which may be produced by electrodeposition) are applied "in a manner similar to wall paper" and secured by an adhesive such as asphalt.

Lincrusta. MILTON K. HUPPUGH (to Decorative Co.). U. S. 1,702,161, Feb. 12. Mech. details of lincrusta manuf. are specified.

Composition for removing paint and varnish. JAMES H. GRAVELL. U. S. 1,700,491, Jan. 29. Free and unionized H_2SO_4 is used with cresylic acid. BuOH and $C_2H_5Cl_4$ also may be added.

Compositions for inking rollers, printing surfaces, etc. I. G. FARBENIND. A.-G. Brit. 292,894, March 16, 1927. Hectograph compns., inking rollers and printers' blankets contain sorbitol or its dehydration products or derivs. such as acetyl sorbitol together with usual materials such as gelatin, glue, resins, oils, fats, waxes, glycol, glycerol, acetin and dextrin, in various mixts.

Cementing celluloid to other materials such as metals. HUGO BRUNINGHAUS (to Henkel-Clauss Co.). U. S. 1,702,226, Feb. 12. Mech. features.

Aggregating particles of wood. FELIX LAUTER (to Lignel Corp.). U. S. 1,702,013, Feb. 12. In forming molded products, particles of wood contg. substantial quantities of natural resin are treated with a soln. contg. CH_2O or other suitable aldehyde, dried and subjected to heat and pressure.

Caulking powder. RUDOLPH E. SINRAM and CLYDE T. HELLER. U. S. 1,701,799, Feb. 12. A powder suitable for use on screw joints of steam pipes comprises a flour such as ordinary wheat flour 15, NH_4Cl 1 and pulverized iron 1 part.

Composition for filling punctures in tires. S. SOKABJI. Brit. 292,835, Nov. 8, 1927. Finely powdered mica 10, plaster of Paris 1, plumbago 20 and dextrin 1 are mixed with water 50 lbs. contg. salicylic acid 1 oz. and glycerol 2 ozs.

Artificial filaments, films, etc. PAUL E. KRISMER. Austrian 111,554, July 15, 1928. Solns. or suspensions of org. substances, *e. g.*, carbohydrates, albumin, vegetable mucilages and gums, are treated with muciparous bacteria, and the viscous masses so obtained are drawn out in known manner into filaments, films, etc., and hardened, *e. g.*, with CH_2O . Milk, especially skim milk, may be treated in the same way. The examples describe the prepn. of filaments from skim milk and *B. lactis viscosi* and from a soln. of glucose and *B. viscosi sacchari*.

Automobile motor "cooling oil." ROBERT E. WILSON (to Standard Oil Co. of Ind.). U. S. 1,700,392, Jan. 29. An oil suitable for use in automobile cooling systems has a flash point not less than 88° , a viscosity below 45 sec. Saybolt at 38° and an initial b. p. not below 205° .

Fumigant. WARREN MOORE. U. S. 1,702,168, Feb. 12. Blocks suitable for use as deodorizers comprise a solid inorg. NH_4 compd. such as $(NH_4)_2CO_3$ and hydrated lime dispersed in a cryst. block of *p*-dichlorobenzene.

Anti-moth preparation. I. G. FARBENIND. A.-G. (Wilhelm Lommel, Heinrich Muzel, Hermann Stötter and Berthold Wenk, inventors). Ger. 469,094, July 14, 1926. Fr. 635,973, June 14, 1927. See Can. 280,549 (C. A. 22, 2820).

Polishing leather, wood, metal, etc. EMIL SEIDLER. Austrian 111,536, July 15, 1928. A dil. soln. of wax in a volatile org. solvent is applied as a fine spray. A combined atomizer and brush for practising the method is described.

Waterproofing pliable wire mesh fabric. FREDERICK E. JOHNSON (to Waters Non-Inflammable Wire Glass Co., Ltd.). Can. 286,736, Jan. 22, 1929. A coating soln. for open-mesh fabric consists of gelatin 33 lbs., glycerol 5 lbs. 2.5 ozs., $Al_2(SO_4)_3$ 3 lbs. 2.5 ozs., Na_2CO_3 7 ozs., 40% formaldehyde 50%, methylene blue 15 lbs., or according to requirements, and 22 gals. of water; the mixt. is cooked for 10 mins. at $180^\circ F$. and then cooled to $135-140^\circ$ when the soln. is ready to receive the mesh fabric.

Marine algae. PAUL GLOESS. Fr. 643,534, April 8, 1927. Marine algae are first distd. so as to obtain a liquid fuel, and *I* and *K salts* are extd. from the residue.

Removing mildew, etc. SOCIÉTÉ H. GOUTHIÈRE ET CIE. Fr. 642,699, Mar. 23, 1927. A mud obtained by double decompn. of Ca lactate and $CuSO_4$ is used either alone or mixed with S, talc, etc., for treating mildew, black-rot, etc.

Stock lick or medicine. ROBERT K. McLENNAN. Australia 9342, Sept. 12, 1927. A stock lick for sheep contains Ca phosphates 14, other Ca compds. calcd. as CaO 23, powd. S 5, Fe and Mg sulfate 3, NaCl 50, molasses 5%, $Mn_2(SO_4)_3$ 3 lbs. to the ton, KI $1\frac{1}{2}$ lb. to the ton. For cattle the $MgSO_4$ and $Mn_2(SO_4)_3$ are omitted.

Fireproofing articles. GEORGES ROUYER. Fr. 643,531, April 8, 1927. Wood, cloth, etc., to be fireproofed is covered with a layer of a soln. of K_2SiO_3 (65%), and then with one or more layers of a colorless varnish composed of "Colle d'or" and pyrene.

Fire extinguisher. EXCELSIOR FEUERLÖSCHGERÄTE A.-G. and OTTO TREICHEL. Fr. 643,393, Nov. 5, 1927. A crystd. addn. product of CO_2 and CCl_4 is used as a fire extinguisher.

Fire extinguishers. SOCIÉTÉ BOUILLON FRÈRES. Fr. 643,167, Oct. 28, 1927. A fire extinguisher consists of a mixt. of a liquid which is a bad conductor of electricity, e. g., CCl_4 , tetrachloroethane, etc., and a substance or mixt. of substances, such as $\text{Al}_2(\text{SO}_4)_3$, varnishes, lacquers or bakelites which will form a resisting insulating layer on the material sprinkled.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

Chemical durability of glass. G. KEPPELER. *Glastech. Ber.* 5, 97(1927); *J. Soc. Glass Tech.* 12, 185-6.—A study of the durability of glasses by the method of curves of equal durability (*C. A.* 21, 4037). Glasses treated were the soda-lime series examd. by Ippach, and the potash-lead series studied by Karmaus.

Thermal conductivity of glasses transmitting ultra-violet light. WILLIAM KUNERTH AND WILLIAM E. BERKEY. Iowa State Coll. *Science* 68, 427(1928).—The thermal cond. measured by Christiansen's method of a no. of glasses transmitting ultra-violet light was less than that for window glass. Also in *Iowa State Coll. J. Sci.* 3, 5, 6 (1928).

Factory smoke, or the coating of glass during melting and working. L. SPRINGER. *Glastech. Ber.* 5, 112(1927); *J. Soc. Glass Tech.* 12, 139-40.—From 15 large glasses coated with a thin bluish white deposit on annealing ("sulfuring") a careful extn. gave a total of 0.553 g. of coating of dark gray color, equiv. to 0.0053 g. of soda, and contg. only a trace of sulfate. Of the total residue 0.3166 g. was insol. in water, and 0.1766 g. insol. in HCl , being chiefly sand. The portion sol. in HCl was largely composed of lime. The lehr was fired by producer gas obtained from lignite, and the impurity was evidently largely composed of ash and impurities from the process of manuf. It was found possible experimentally both by burning lignite and S near glassware to produce the sulfuring effect. By use of a gas of high SO_2 content and subsequent heating of the ware to a sufficiently high temp. it was possible to "burn in" the white residue, so causing it to disappear. There was no relationship between the deposit and the quality of annealing. Analysis of the S content of a producer gas, by absorbing the S gases in alkali, oxidizing and estg. as sulfate, gave a value of 1.91 vols. % of SO_2 . S. also considered the causes of the white deposit formed on the surface of glass during working.

Elastic constants of fused quartz. Change of Young's modulus with temperature. H. D. H. DRANE. *Proc. Roy. Soc. (London)* 122A, 274-82(1929).

Insulation of roofs of glass furnaces. ROBERT D. PIKE. *J. Am. Ceram. Soc.* 12, 56-61(1929).

Clay in 1927. JEFFERSON MIDDLETON. Bur. Mines, *Mineral Resources of the U. S.* 1927, Pt. II, 257-68 (preprint No. 23 published January 15, 1929).

Experiments on the purification of clay by electrophoresis. A. S. TAL. *Trans. State Expt. Inst. Silicate (Moscow)* 1927, No. 21, 115-31. The electrophoresis of clay was resorted to in an attempt to purify it for various purposes. At first the ordinary lab. outfit was used, but later a bath of a semi-factory style was introduced. The anode used after a series of trials was hard lead (an alloy of Pb and 14% Sb). Various electrolytes were tested: sol. glass, soda and ammonia. The latter gave the least difficulties and was used throughout the 250 expts. With a current of 80 v. the gas accumulations at the anode were a hindrance and a depolarizer was introduced. Peat ext. was found to serve the purpose. The final outlay of the expt. was as follows: the clay was ground in a ball mill, sieved through a 900-mesh sieve, mixed with H_2O (2 kg. of clay per l. of H_2O), ammonia added in excess, the current (0.008-0.012 amp. per sq. cm.) varied between 75 and 120 v. The clay thus obtained upon heating gave a lighter product and its contracting upon heating to high temps. was greater than that of contracting when heated up to 100° . Tests were also made on methods of removing the Fe present in forms other than silicates. The magnet was resorted to but without success which was attributed to the weak magnet used. A powerful magnet is contemplated.

Some aspects of plasticity and related properties of clays. D. R. IRVING AND W. F. DISTRICH. *J. Am. Ceram. Soc.* 12, 14-29(1929).—The Talwalkar-Parmelee plasticity

app. is valuable in distinguishing between clay types. Results are given for various California clays and several widely known clays. No correlation was noted between adsorption of malachite green or of methylene blue and phys. properties of the clays.

C. H. KERR

Vanadium and molybdenum compounds in clays. L. A. PALMER. *J. Am. Ceram. Soc.* 12, 37-47(1929).—Eight light-burning clays and shales contg. small quantities of insol. V and Mo compds. were studied. During slow firing, sol. salts of these elements were formed which later appeared as a yellow-green efflorescence on the fired clay. The color was due chiefly to alkali vanadates. The use of either Na_2SiF_6 or CaF_2 was effective in eliminating the efflorescence.

C. H. KERR

The rate of oxidation of porcelain and ball clays. HOBART M. KRANER AND E. H. FRITZ. *J. Am. Ceram. Soc.* 12, 1-13(1929) The rate of CO_2 evolution was detd. by passing a 4% $\text{O} + 96\%$ N gas mixt. over a bar of clay or porcelain while it was being heated. The H_2O and CO_2 evolved were collected in P_2O_5 and soda lime, resp., with 1 hr. weighings. Oxidation took place rapidly between 200° and 550° in both clay and porcelain, whereas 750° has generally been considered the most efficient temp. for oxidation.

C. H. KERR

The problem of active silica. Soluble silica in clays. A. FIOLETOVA. *Trans. State Expt. Inst. Silicate* (Moscow) 1927, No. 21, 111-3. Clay samples were dried at $100-110^\circ$, ground in an agate mortar, treated for 1 hr. with const. stirring with N HCl following the method of Dementev (V. G. Dementev, Scientific Principles of the Technic of Cement. *Isvestia Kievsk. Politech. Inst.* 1905: a text book). The 2 clays treated gave up 0.05 and 0.09% SiO_2 . The clays were then heated to 530° , the sample being allowed to cool 2.5 hrs. between the 2 heatings. After each heating the clays were treated again as above with HCl . After 2.5 hrs. cooling the amts. of SiO_2 extd. from the 2 clays were 0.25 and 0.17%. When extd. immediately after heating, the SiO_2 content was 0.29 and 0.17%. The clays were also heated to 1300° and in this case the HCl extract gave 0.21% SiO_2 for the first sample and none for the other.

J. S. JOFFE

The determination of the reaction of clay and kaolin. P. N. GRIGORÉV. *Trans. State Expt. Inst. Silicates* (Moscow) 1927, No. 21, 133-6. Grigorév describes a method of titrating clay exts. (200 g. in 1000 cc. H_2O), using phenolphthalein and methyl orange as indicators.

J. S. JOFFE

The thermal insulation of kilns. C. PRESSWOOD. *Claycraft* 1, 286-8(1928); *Biochem. Sci. Abstracts* 1, 196-7. Brick-burning is said to be inefficient, and various improvements are suggested such as improved design in kilns, flues and stacks, the use of forced draught, and of continuous kilns.

H. G.

Terra cotta kiln slab investigation. R. L. CLARE, G. H. BROWN AND F. B. ALLEN. *J. Am. Ceram. Soc.* 12, 62-8(1929).

C. H. KERR

Insulation in the ceramic industry. E. A. PHOENIX. *J. Am. Ceram. Soc.* 12, 18-25(1929).—Advantages of sil-o-cel brick are shown.

C. H. KERR

Progress in the refractories industry. J. SPOTTS McDOWELL. *Blast Furnace Steel Found.* 17, 88-90(1929).

E. H.

Progress in refractory materials. ALFRED B. SEARLE. *Metal Ind.* (London) 34, 71-73(1929).

E. H.

Discussion on "prevention of disintegration of blast-furnace linings." R. P. HEILER. *J. Am. Ceram. Soc.* 12, 30-1(1929); cf. *C. A.* 22, 2251.—The recommendation that blast furnace brick be especially treated to convert the Fe oxides to Fe_2O_3 is at least open to question.

C. H. KERR

The use of chainotte, stoneware and porcelain as apparatus in the chemical industry (SINGER) 1. Theoretical considerations in electric kiln design (KELLEHER) 4. The refractory earthen of Novarese (MILANI) 8. Apparatus for marking glass articles such as lamp bulbs (U. S. pat. 1,701,348) 1.

Glass. MONTAN- UND INDUSTRIALWERKE VORMALS JOH. D. STARCK & ARTHUR POLLAK. Fr. 643,711, Nov. 9, 1927. The chamber contg. the glass has a vault, which may be of carborundum, sepg. this chamber from direct contact with the heating gases.

Double glass. YVON BRANCART. Fr. 643,197, Oct. 28, 1927. A double glass is made by rolling on a previously rolled layer of glass a second layer of fluid glass so that the second layer is intimately welded to the first.

Composite glass. CORNING GLASS WORKS. Fr. 643,317, Nov. 3, 1927. A composite glass is made by placing between the unpolished faces of 2 sheets of glass a reinforcing plate in transparent material and uniting the 3 in known manner, then grinding and polishing the outer faces.

Composite glass sheet. PERCY J. PORT (to James Newton). Can. 286,367, Jan. 8, 1929. A coating of white of egg and distd. water is applied on one face of each of two sheets of glass, dried, covered with a soln. of pyroxylin and again dried. A sheet of transparent celluloid of the same size as the glass sheets is inverted in a bath consisting of a soln. of commercial Me_3NH contg. a small quantity of AcOH , the celluloid sheet is placed between the coated surfaces of the glass sheets and all are pressed together in a moderately heated press.

Laminated glass. JOHN L. DRAKE (to Libbey-Owens Sheet Glass Co.). U. S. 1,701,147, Feb. 5. Sheets of glass are united by an intervening sheet of non-brittle material such as "cellulose compn." carrying a film comprising a vegetable oil and camphor.

Laminated glass sheets. J. DUCLAUX (to Société d'étude des verres et glaces de sureté). Brit. 293,052, July 1, 1927. Yellow coloration is prevented by using as the intervening sheet for uniting glass sheets regenerated cellulose formed from any of its sol. ethers or pptd. from a soln. such as cuprammoniacal cellulose soln. or by use of polysaccharides such as caroubin. When celluloid is used, yellow coloration can be prevented by excluding radiations below the wave length 3300 A. U. and for this purpose there may be incorporated in the adhesive used salts such as stannate, antimoniate, molybdate, or a crystalloid or colloid salt of Pb, Hg, Mo, Th, Bi, U or org. compds. such as a ketone of high mol. wt., an aromatic aldehyde, a phthalein, an aromatic hydrocarbon, an aliphatic or aromatic acid having a double bond, a ketonic function, a quinone or nitrated deriv. or one of its salts, a compd. with a "mixed function" such as citral or dibenzalacetone or a substituted urea. PrOH , BuOH and AmOH also may be used for treating the celluloid and castor oil may be added. Brit. 293,053 specifies grinding or coating the contact surfaces of the glass sheets to obtain plane surfaces.

Glass articles. COMPAGNIES RÉUNIES DES GLACES ET VERRES SPÉCIAUX DU NORD DE LA FRANCE. Fr. 642,782, Mar. 31, 1927. Molten refined glass is obtained in a continuous manner and at const. level by the combination of one or several crucible furnaces in which the glass is melted and refined and a small basin furnace which receives the molten glass and transmits it to the app. for making articles from the glass.

Glass-making machines. THE UNITED GLASS BOTTLE MANUFACTURES, LTD. Fr. 642,859, Oct. 12, 1927.

Apparatus for blowing glass bottles, etc. WILLIAM J. MILLER (to William J. Miller, Inc.). U. S. 1,700,326, Jan. 29.

Water-cooled roller construction (suitable for use in sheet glass manufacture). SOC. ANON. DES MANUFACTURES DES GLACES ET PRODUITS CHIMIQUES DE ST.-GOBAIN, CHAUNY, ET CIREY. Brit. 293,013, June 30, 1927.

Apparatus for drawing sheet glass. GEORGE G. ROBERTS (to Virginia Plate Glass Corp.). U. S. 1,700,420, Jan. 29.

Apparatus for drawing sheet glass. JOSEPH M. NEENAN and JAMES P. WEAVER (to Libbey-Owens Sheet Glass Co.). U. S. 1,701,161, Feb. 5.

Apparatus for drawing sheet glass. ARTHUR E. FOWLE (to Libbey-Owens Sheet Glass Co.). U. S. 1,701,151, Feb. 5.

Apparatus for drawing sheet glass. CHARLES W. SWOPE (to Libbey-Owens Sheet Glass Co.). U. S. 1,701,165, Feb. 5.

Apparatus for drawing glass in continuous sheets. R. L. FRINK. Brit. 292,118, March 11, 1927.

Apparatus for drawing and cooling sheet glass. Horace E. Allen (to Libbey-Owens Sheet Glass Co.). U. S. 1,701,170, Feb. 5.

Apparatus for cooling plates of glass. YVON BRANCART. Fr. 643,198, Oct. 28, 1927.

Drawing sheet glass. ARTHUR E. SPINASSE. U. S. 1,701,890, Feb. 12. Mech. features.

Abrasives for polishing glass. SOC. ANON. DES MANUFACTURES DES GLACES ET PRODUITS CHIMIQUES DE SAINT-GOBAIN, CHAUNY, ET CIREY. Brit. 292,104, June 13, 1927. Abrasives such as emery, corundum, quartz or carborundum are prepd. for use by prolonged grinding, followed by suspension in a liquid having a pH of about 11 or 12 which is favorable to retention of fine particles in suspension for a prolonged time. The suspended material is decanted and flocculated by neutralization. Excess CaCO_3 is removed from the water used if present.

Abrasives. SOC. ANON. DES MANUFACTURES DES GLACES ET PRODUITS CHIMIQUES DE ST.-GOBAIN, CHAUNY, ET CIREY. Brit. 292,811, June 23, 1927. An abrasive material is prepd. by heating (suitably to about 1300°) a 1% and 2% on the or less of a material serving to liberate gases having

alumina of the bauxite such as fluorides or fluosilicates of alkali or alk. earth metals.

Electric furnace for the manufacture of articles in silica glass. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 33,288, Mar. 30, 1927. Addn. to 595,044.

Brick-making machine. SOCIÉTÉ DES FONDERIES ET ATELIERS DE CONSTRUCTIONS MÉCANIQUES DE PORTILLON. Fr. 643,433, Nov. 7, 1927.

Hollow quartz articles. I. G. FARBERIND. A.-G. Fr. 642,822, Sept. 15, 1927. A furnace is used which acts both as fusion furnace and mold.

Light weight ceramic material. RICHARD ERICSON (to U. S. Gypsum Co.). U. S. 1,702,076, Feb. 12. In order to form a porous product which is suitable for structural purposes, a plastic mixt. of argillaceous material and water is incorporated with a tenacious foam which may be formed of soap bark and water, and the mixt. is shaped, dried and heat treated to obtain a hardened cellular product.

Composition for ceramic articles. AMERICAN ENCAUSTIC TILING CO., LTD. Brit. 293,069, Feb. 28, 1927. A bisque mixt. is used contg. magnesia about 27%, alumina about 6% and silica about 61% together with a small quantity of water; it is fired at a temp. limited to a narrow range at its max. A small proportion of Ca may be added (less than the quantity of alumina) and the finished articles may be treated with paraffin as a waterproofing agent.

Ceramic objects. THOMAS S. CURTIS. Fr. 642,828, Sept. 20, 1927. Ceramic objects are made from a compn. which will solidify when not agitated and which will become fluid when agitated and is composed of a finely divided refractory material submitted to agitation. The fashioning to the required form is effected while the solid particles of the compn. are in movement and without change of temp. and the agitation is stopped to allow the whole to solidify. An electrolyte serves to reduce the viscosity of the mass, and a vacuum is used to remove air from the compn. Fr. 642,829 describes a suitable app. for the above process. Fr. 642,830 describes a ceramic compn., and process of making it, contg. principally mullite and crystals of corindon, the interstices between the crystals being filled with glass. Cf. C. A. 23, 1236.

Ceramic product. PATENT-TREUHAND-GES. FÜR ELEKTRISCHE GLÜHLAMPEN M B H. Fr. 643,282, Nov. 2, 1927. See Brit. 281,249 (C. A. 22, 3505).

Ceramic ware decorated with colored tiles flush with its surface. ROGER B. SHERMAN. U. S. 1,701,313, Feb. 5.

Furnace for ceramic materials. HARRY T. BELLAMY and WILLIAM H. GROVES (to Western Electric Co.). U. S. 1,702,033, Feb. 12.

Furnace with a tunnel-like chamber for heat treatment of ceramic articles. WILLIAM G. BERGMAN (one-half each to Dana P. Ogden and Ermin F. Plumb). U. S. 1,701,223, Feb. 5. Structural features.

Refractory material. DEUTSCHE GOLD- UND SILBER-SCHNEIDANSTALT VORM. ROESSLER. Brit. 292,958, June 27, 1927. The magnesia obtained by the action of air or steam on $MgCl_2$ (such as that obtained as a by-product in the treatment of final potash lyes) may be treated with water or solns. of salts or acids, preferably with addn. of $MgCl_2$ or Zr chloride, and the plastic material thus obtained is fired.

Refractory materials. DEUTSCHE GASGLÜHLICHT-AUER-GES. Brit. 292,529, June 21, 1927. Highly refractory oxides such as those of Zr, Th and Be are rendered plastic for molding or casting by the addn. of up to 5% of oxides of Mg or Al or both and of a small quantity of a soln. of a salt of one or more of the metals, the oxides of which are used. Part of the salt soln. may be replaced by free acid.

Refractory materials. GENERAL ELECTRIC CO., LTD. Brit. 292,997, June 29, 1927. Solid bodies of high density are formed by first sintering W powder, CaF_2 powder or other raw materials, preferably highly compressed, to form a porous body and then subjecting the latter to high pressure between members (of an app. which is described) which offer little resistance to lateral expansion, while heated to above redness but below the temp. at which the previously compressed body would attain a d. of 85% that produced by fusion.

Refractory objects. GEORGES L. CHAUDRON and AUGUSTE L. DESMARQUEST. Fr. 643,473, Apr. 1, 1927. Crucibles or other refractory objects are made by baking com. MgO in an elec. furnace, grinding and making into a paste with a suitable binder, e. g., tar. This paste is afterwards molded under high pressure and baked out of contact with a flame to 1400° , then re-baked to between 2000° and 2200° in an elec. resistance furnace.

Casting refractory materials such as silica or zirconia. GORDON S. FULCHER (to Corning Glass Works). U. S. 1,700,288, Jan. 29. The molten refractory material is poured into a mold, a portion of the material is allowed to solidify and shrink, and addnl.

molten refractory material is fed into the mold to compensate for the shrinkage of the molten material first poured.

Silica. QUARTZ ET SILICE. Fr. 642,692, Mar. 23, 1927. See Brit. 287,522 (C. A. 23, 495).

Fused silica. H. P. HOLLNAGEL (to British Thomson-Houston Co.). Brit. 292,624, June 23, 1927. A mass of fused silica is heated to about 1400° and then shaped while plastic by the progressive application of localized pressure over its surface. Various mech. details are described.

Resistant material. METALLBANK UND METALLURGISCHE GESELLSCHAFT A.-G. Fr. 643,638, Sept. 1, 1927. Natural rocks such as olivine, peridot and dunite are used for making refractory and chemically resistant material. Rocks contg. between 40 and 55% of MgO are best; the content of SiO₂ should not pass 48%.

Electric resistance materials. K. B. McEACHRON (to British Thomson-Houston Co., Ltd.). Brit. 292,110, June 13, 1927. A cryst. resistance material suitable for lightning arresters and similar safety devices carries a large current only above a certain voltage and may be made by mixing carborundum with a binder such as clay cement, Pb borate or glass, drying, heating and firing. The characteristics of the material can be regulated by altering the proportion of free C in the carborundum as by oxidation in free O or with oxidizing agents such as KClO₃, HNO₃, or HNO₃ plus HF and adding C in the form of graphite or lampblack. The cond. may be increased by adding Te, W, Co, Ni, Mo, Fe or Si and, instead of carborundum, zincite, galena and psilomelane may be used. The proportion of free Si in the material may be adjusted to obtain desired characteristics.

Roofs of furnaces. ALFRED-NUMA DE SAINTE-EDME BORNE BONET. Fr. 643,232, Oct. 29, 1927. The refractory bricks of suspended furnace roofs are trapezoidal in shape so that the joints become wedged.

Furnace lining. COMPTOIR TECHNIQUE ALBERT KNAFF and LEON MAYER. Ger. 469,863, Apr. 10, 1925. A lining for converter and other metallurgical furnaces is made by mixing powd. sintered dolomite with ground hard pitch and the mixt. is formed as required in known manner.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Tentative standard specifications for reinforced concrete culvert pipe. ANSON MARSTON, et al. *Second Rept. of the Joint Concrete Culvert Pipe Committee 1928*, 3-15 E. J. C.

Capping device for concrete cylinders. P. J. FREEMAN. *Eng. News-Record* 101, 777(1928).—A description of the method of capping concrete test cylinders employed by the Allegheny County Dept. of Public Works, Pittsburgh, Pa. Perfect caps can be placed on any specimen, regardless of its irregularity, in 10 mins. A quick hardening compd. known as Baselit is used; it will adhere to any concrete. The crushing strength of the compd. is about 8000 lbs. per sq. in. The cost for material is approx. 8¢ per specimen.

R. E. THOMPSON

Test of curing methods for concrete road slabs. D. D. MCGUIRE. *Eng. News-Record* 101, 813-4(1928). Brief details are given of methods being employed in an extensive study of curing methods being carried out by the Dept. of Highways, Tenn. Tests conducted to date have shown that great variations in strength occur when different kinds of earth are used for curing, red clay giving strengths as much as 16.7% lower than brown loam.

R. E. THOMPSON

Significant tests of frost action on concrete. WM. H. BATCHELDER. Minnesota Highway Dept. *Eng. News-Record* 101, 882(1928). Tests were made of frost action on concrete mixed and cured under wet burlap at 70° F. (A) and at 40° F. (B). Freezing immediately after casting resulted in 31% loss of strength in A and 69% in B. If

—Based on

hrs., except, of course, that the strength does not increase while concrete is curing. Effect of alternate freezing and thawing is marked if freezing commences immediately after casting and decreases with addnl. initial curing.

R. E. THOMPSON

Corrosive attack of moorland water on concrete. W. T. HALCROW, G. B. BROOK AND R. PRESTON. *Water and Water Eng.* 30, 579-86(1928).—In hydroelec. plant installations, the loss of head in aqueducts is important, particularly in large tunnels

such as the 15-mile Lochaber tunnel. Expts. show that it is possible to restrict the deterioration of concrete surfaces, and hence the increased friction losses, but at considerable cost. If the surface of the lining deteriorates, the coeff. of friction increases and there results a greater loss of head for an equal quantity of H_2O and also a greater loss of power. Smooth coating will prevent friction. Concrete made with a good aluminous cement will keep deterioration at a min. but costs approx. twice as much as portland cement. With the exception of Straffordshire blue bricks, no other materials give promise of permanent resistance to corrosive attack by moorland waters.

C. R. F.

Shrinkage of mortar and concrete. A. W. KNIGHT. *Eng. News-Record* 101, 981 2(1928).—A criticism of the paper of Levens (cf. C. A. 22, 4754) on the shrinkage effect of Celite in mortar and concrete. Reply. A. S. LEVENS. *Ibid* 965-6.

R. E. THOMPSON

Fires in houses built of concrete or clinker blocks (Winget System). G. PARKER. *Munic. Eng. Sanit. Record* 81, 644(1928).—Houses built of concrete blocks 6 parts crushed boiler clinker ($1/2$ and dust) to 1 part cement are described. These are considered almost fireproof. Aggregates containing quartz such as flint or granite will cause shelling or "spalling" during heating. Crushed firebricks are perhaps the ideal fire resistant material but whinstone also is good.

C. H. BADGER

Cold emulsions. G. BELSON CHILVERS. *Munic. Eng. Sanit. Record* 81, 688-9 (1928).—A discussion on their use in road making.

C. H. BADGER

The advantages of cold dressings. O. N. EDWARDS. *Munic. Eng. Sanit. Record* 81, 702(1928).—The use of cold bitumen emulsions on roads is discussed.

C. H. B.

New and simple method for determining moisture content in aggregates. WALTER M. DUNAGAN. *Eng. News-Record* 101, 738 9(1928).—A direct wt.-displacement method for detg. the moisture content of aggregates is described; it is believed to be more rapid and less subject to error than other current methods. The time required to carry out a test need not exceed 5 min. (See following abstr.)

R. E. THOMPSON

Determining moisture content in aggregates. H. C. MCCALL. *Eng. News-Record* 101, 966(1928).—A discussion of the paper by W. M. Dunagan (cf. preceding abstr.), in which attention is drawn to errors to which the method suggested by D. is subject. The method is considered much the simplest and fastest for detg. added absorption of porous aggregates which are dry or contain less moisture than the total absorption. The most dependable method for sand is to det. absorption and then obtain total moisture by drying to const. wt.

R. E. THOMPSON

Cements and plastics (NAGEL, GRÜSS) 18. Coverings for walls, roofs, vehicles, tools, etc. (Brit. pat. 292,621) 18. Granulating raw cement materials, etc. (Brit. pat. 292,984) 13.

Cement. M. GENSBAUER. Brit. 292,492, June 20, 1927. Raw cement materials are ground or mixed with fuel and pressed into lumps, which are fed into a rotary kiln.

Cement. C. PONTOPPIDAN. Brit. 293,035, June 30, 1927. A hydraulic cement clinker has a ratio of basic to acidic materials of not less than 2.2 and a ratio of silica to alumina and ferric oxide of not less than 3.4 and the raw materials are ground so that 99% passes a 200 mesh sieve. The cement produced is preferably finely ground and may be mixed with various other materials.

Cement. JOHAN A. BONTHRON and TURE R. HAGLUND. Fr. 643,024, Oct. 26, 1927. In the prepn. of a substance contg. Ca aluminate for cement, the primary material contg. Al_2O_3 is treated with a reducing agent for the SiO_2 , with addn. of part only of the CaO contg. material. The rest of the CaO-contg. material is afterwards added to the fused bath. To facilitate the reduction, Fe turnings or Fe ore is added.

Porous cement. JULIUS MEYER and EMIL ASMUS. Ger. 469,864, June 19, 1927. A porous cement is made from mineral substances capable of setting and Ca alloys which are capable of liberating gases in the presence of water and in which the Ca is mixed with Zn, Ca-Mg or Ca-Mg-Zn alloys are suitable.

Waterproofing cement compositions. ORLANDO A. COLLINGS (to Silica Products Co.). U. S. reissue 17,207, Feb. 5. See original pat. No. 1,650,864 (C. A. 22, 675).

Porous concretes. J. MEYER and E. ASMUS. Brit. 292,468, June 18, 1927. Cementitious material is admixed with a powdered alloy of Ca with Zn or Mg or both in which the Ca is preponderant, so that gas is generated by the action of water.

Device for ascertaining the hygroscopicity of building materials. OTTO FÖPPL and EWALD PERTZ. Ger. 470,202, Mar. 23, 1927.

Paving compositions. J. HINES. Brit. 292,871, Jan. 20, 1928. Tar macadam in which the tar has been strengthened by an admixture of bitumen is treated with a colloidal emulsion of bitumen in water or other suitable liquid, to prevent premature hardening; the emulsion may also be used for reconditioning a material which has already set by drilling holes in the mass and filling these with the emulsion.

Bituminous pavement. RALPH C. HEATH (to Barber Asphalt Co.). U. S. 1,701,497, Feb. 12. Structural features.

Use of rubber on a concrete foundation for road surfaces. J. JAGURS and F. W. McCahon. Brit. 292,681, March 23, 1927. Mech. features. The rubber is vulcanized *in situ* and an accelerator may be used.

Slag, scoria, etc. SOCIÉTÉ GÉNÉRALE MÉTALLURGIQUE DE HOBOKEN. Fr. 643,507, April 5, 1927. Slags, scoria, waste from mines, etc., are made into paving blocks and the like by a slow cooling of the molten products in the absence of air.

Artificial stone. A. TETZNER. Brit. 292,925, June 24, 1927. Clay 6 and sand 6 parts are ground to a "meal-like" mass and cement 1 part and water are added.

Molding blocks or slabs of imitation marble. GEORGE E. KENDALL. U. S. 1,701,619, Feb. 12. Mech. features.

"Marble substitute." K. STICHA, J. HUBACEK and J. KNEIFL. Brit. 292,388, Sept. 5, 1927. A glazing compn. is applied to glass or other suitable smooth surface at a temp. of about -2° , dried and polished. The compn. may be formed from Na sulfate 2, black coloring matter 10, red coloring matter 2, waterglass 16 and water 28 parts together with some NH_4Cl .

Colored material suitable for use as a floor covering. GLENN H. WILLIS (to Tanseib Co.). U. S. 1,701,220, Feb. 5. A base stock such as a rubber mixt. is colored to a desired shade (suitably by a red pigment) and fibrous or other filler is colored to match the color of the base stock and then mixed with the latter, formed into sheets or other desired shape, vulcanized, and the surface of the formed article is then removed (suitably by grinding or use of a wire brush) in order to improve its appearance.

Sheet material for roofing. CHESTER E. RAHR and RALPH E. DRAKE (to Anaconda Sales Co.). U. S. 1,700,774, Feb. 5. A base such as asphalted felt carries a facing of granular material such as crushed slate with a metal lying in the interstices only of the facing.

Uniting metal surfacing material to asphalted roofing sheets. JULIUS H. GILLIS (to Anaconda Sales Co.). U. S. 1,701,918, Feb. 12. An app. is described employing elec. heating to soften the asphaltic material where the metal coating is applied under pressure.

Apparatus for coating roofing felt, etc. WILLIAM FREEGARD (to Barber Asphalt Co.). U. S. 1,701,878, Feb. 12.

Impregnation of wood. CHEMISCHES LAB. FÜR ANSTRICHSTOFFE G. M. B. H. (Richard Weithöner, inventor). Ger. 470,199, Nov. 26, 1924. Addn. to Ger. 414,483. Wood is impregnated and primed for the subsequent application of linseed oil and varnish paint by using as the impregnating medium, wood oil heated with petroleum jelly and diluted with a solvent contg. a preservative.

Apparatus for perforating wood preparatory to treatment with preservative materials. CLARENCE N. GRAM (to Valentine-Clark Co.). U. S. 1,701,324, Feb. 5.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

Calorific equivalent of fuels. ANON. *Izvestiya Teploekkh. Inst. (Trans Thermo-Tech. Inst. (Russia))* 1927, No. 5, 55-62.—7000 kg.-Cal. is established as a unit and the following fuels are compared by their heat value: Moscow hard coal Kuznetskii coal, anthracite from Donetz, hard coal from Donetz, etc. A classification of various fuels by their sources is also given.

Pulverized fuel locomotives. J. CLUBLEY ARMSTRONG. *Engineer* 146, 495-7 (1928).—Successful trials for 6 months on the German State Ry. are reported. A pulverized brown coal was used, its compn. being H_2O 11.67, ash 9.04 and combustible 79.29%. Lower calorific value was 9700 B. t. u. and fineness of milling 90% through a sieve with 4900 meshes per sq. cm.

The difference between Kraemer-Sarnow and ring and ball values. H. MALLISON. *Teer u. Bitumen* 26, 602-3 (1928).—It is pointed out that one value cannot be calcd. from the other by a simple conversion formula because the difference depends mainly on the slope of the viscosity-temp. curve of the material tested.

F. S. G.

A revised Mollier chart for steam, extended to the critical point. J. H. KEENAN. Stevens Inst. of Technology. *Mech. Eng.* 51, 109-14(1929). E. H.

Recent developments in the utilization of bituminous coal. ANON. *Mech. Eng.* 51, 142-6(1929); cf. C. A. 23, 953. E. J. C.

Laboratory self-ignition test for some Donetz coals. M. I. KUZNETZOV. *Izvestiya Teplolek. Inst. (Trans. Thermo-Tech. Inst. (Russia))* 1927, No. 7, 43-6.—In a glass tube, which acts as a thermostat and is filled with a high-boiling liquid such as heavy mineral oil and which is heated by elec. current sent through a resistance coil wound and properly insulated with asbestos, a smaller glass tube is inserted with an outlet through the bottom of the thermostat. A layer of wire gauze is placed in the inner tube on which 15 g. of coal under test are loosely placed. The app. is closed with a cork; thermometers are provided for the oil and the coal. The coal sample is first brought up to the desired temp. and a steady stream of air or O₂ is led through the bottom, escaping through a tube in the cork. The initial temp., i. e., the increase of the temp. of the coal due to the beginning combustion is then recorded. A table including tests of 13 samples of Russian coal with O₂ and air is given, also their classification according to Gruwer and Denstedt. A. A. BOEHLINGK

How to avoid fire in storing Indiana screenings. M. A. TUTTLE. Knox Consolidated Coal Co., Indianapolis, Ind. *Power* 69, 271(1929).—Foundations should be firm, level and well-drained. The safe depth of piling can best be detd. by temp. observations. Segregation of fines by the method of dumping used sometimes is responsible for fires. Firmness is a primary essential because of better heat cond. and less air circulation. D. B. DILL

Hydrogenation tests on different Spanish coals. ANTONIO MORA. *Anales soc. españ. fis. quim.* 26, 113-20(1928).—The coals subjected to hydrogenation at high temp. and pressure, from modern geological formations, lignites and peats, show that this method can be used to give combustible oils. The yield of hydrocarbons is better than that obtained with English and German coal, and the return on the mineral oil is more advantageous because of the lower value of the raw material. E. M. SYMMES

Contributions to the knowledge of Moscow coal. H. BODE AND G. FEIST. *Braunkohle* 27, 1070-87(1928).—The industrial history and geological features of the Moscow mining district are briefly reviewed. Petrographical investigation of the coal showed that it existed in two different principal types. One of these is a typical dull brown coal, instead of a cannel or a bituminous coal as erroneously designated in the previous literature. Its petrographic details are described and illustrated. It is to be regarded as a humus coal. In this coal, especially along the seams, layers of a putrefied deposit occur which was formerly designated as boghead. The petrographic investigation showed a considerable proportion of boghead constituents, but it consisted principally of microspores, the characteristic constituent of cannel coal. The brown coal differed somewhat from German brown coal. It yielded only 4% tar and no cellulose. The cannel coal yielded 4 or 5 times as much tar as the usual brown coal. A number of new analyses of both coals are given. The coal is discussed with reference to its value as a fuel and for distn., generators and briquetting. An extensive bibliography is appended. F. S. GRANGER

The rational cleaning of coal. R. LESSING. *Gas J.* 184, 850-3(1928).—A general review and statistical discussion of the various sepn. processes including the effects on the petrological elements of the coal. F. S. GRANGER

Coal liquefaction. The Bergius process. E. W. SMITH. *Times Trade and Eng. Supplement* (London) 23, 28(1928).—A comprehensive review of process, app. and costs. The matter (in England) is of importance only as a war-time measure when fuel oil is high, unless the recent developments in Germany have made it possible greatly to increase the yield of the more valuable motor fuels. E. M. SYMMES

Low-temperature carbonization plant at Dalmarnock. JOHN B. C. KERSHAW. *Engineer* 146, 651-2(1928).—The MacLaurin process is operated with producers of the continuous internally heated type, 8 × 36 ft. in dimensions and resembling a small blast furnace. During the two years ending May 31, 1928, the plant operated at a loss. This was in part related to industrial conditions and in part to difficulty in selling the smokeless by-product fuel, *kincole*, which is objectionable on account of its tendency to decrepitate when heated. D. B. DILL

The application of the Lurgi low-temperature carbonization process to brown coal. F. A. OETIKEN AND O. HUBMANN. *Braunkohle* 27, 1097-1104(1928); cf. C. A. 22, 4766.—The difficulties in the practical realization of circulating gas carbonization and the adaptation of the Lurgi process to the large oven are discussed. The feasibility of the process is demonstrated by examples and results from industrial practice. The

present stage of development promises application to young coals of all kinds.

F. S. GRANGER

A new French low-temperature carbonization oven, Bonnevie type. ANON. *Brennstoff u. Wärmewirtschaft* 10, 481-3(1928).—It consists of 3 superimposed horizontal chambers with slow mech. stirring. The coal, starting at the top, passes successively through each chamber horizontally and through an outside chute into the next lower one and is exposed to a higher temp. in each, emerging from the bottom one into a water-cooled screw conveyor, as semi-coke. The chambers are heated externally by a gas burner. The distn. products are aspirated separately from each chamber upward through a common vertical manifold, downward through a cooling tower and then through a washer.

F. S. GRANGER

The Babcock low-temperature coal distillation system. ANON. *Gas J.* 184, 469 (1928).—The retorts are operated as an integral part of the Dunstan Power Station of the Newcastle-upon-Tyne Elec. Supply Co. Its purpose is to furnish coke for the boilers and to produce motor spirit and other by-products. The operation is continuous. The coal is dried and preheated by the boiler flue gases, to avoid interference of gas-flow through the coal by condensation in the retorts. The distg. medium consists of steam and combustion products obtained by first burning a suitable fuel, powdered coal or gas, in a small combustion chamber immediately connected with the retort from below. Steam is then introduced into the connecting duct or tempering chamber to produce distg. gases of the required compn. at (650-700)°. The hot coke is discharged continuously through breakers, a rotary sealing valve and a screw conveyor to the stoker hopper. The gas passes outside the building through a tar extractor, is stripped of oil and finally burned under the boilers.

F. S. GRANGER

Chemical changes in coal brought about by coking and by oxidation. O. KUNLE. *Brennstoff-Chem.* 9, 295-8(1928).—The influence of increasing coking temp. on coke yield and compn. is detd. in app. ordinarily used for the detn. of volatile matter. The effect of preliminary oxidation at low temps. on the yield of volatile and coking power is also studied. E. g., heating a Saxon bituminous coal 1 hr. at 225° destroyed the coking power and increased the volatile 1%. In 10 hrs. time at 225° the O₂ content rose from 9.93 to 23.86%. The O₂ content of fusain similarly treated increased from 5.48 to 17.42%.

J. D. DAVIS

Chemical reactions in the gasification of crude brown coal. HERBERT KNOTT. *Gas u. Wasserfach* 71, 1218-21, 1242-5, 1259-63(1928).—Chem. reactions in the fuel bed of a Heller gas producer, gasifying crude brown coal, were studied. Gas samples were taken from 4 locations at which the temp. of the gas was also measured. The results of the gas analyses correspond to the water gas equil. rather than to the water gas equation. In the generator, the gas temp. is always higher than the fuel temp. Thermal relations were discussed and the literature was reviewed.

R. W. RYAN

Contribution to the study of humic compounds in low-grade coals and lignites. FRAN PODBREZNIK. *Bull. inst. pin* No 51, 193-6, No 52, 209-14, No 53, 287-8 (1928).—P. sepd. 2 humic acids from the lignites of the Siorac-de-Belve's mines in Dordogne: a humic acid proper and hymatomelanic acid. Their physical properties were studied. By means of quant. analyses of some of the salts of the non-crystallizable acids their approx. mol. wts. were detd. The mol. wt. of the humic acid proper was found to be approx. 1120 and that of the hymatomelanic acid, assuming it to be tetrabasic, about 720. The role of the humic acids consists in the physical envelopment of the bitumens in such a way that the latter can yield the largest amt. of tar only after the removal or destruction of the humic acids. Under the influence of not too high a temp. humic acids change progressively into humic lactones, dilactones and oxetones. According to this change the coking value of lignites and coals can be enhanced by preheating at temps. below 300° and progressively driving off water and CO₂.

R. THIESSEN

The construction of a gas works. W. M. FOX. *J. Chem. Met. Mining Soc. S. Africa* 29, 55-63(1928).—The av. yields per ton of coal carbonized in gas works practice are gas 15,000 cu. ft. of 470 B. t. u./cu. ft., coke for sale 900-1000 lbs., tar 12-16 gals., and 25-33 gals. of 10 oz. strength ammonia liquor. Products obtained by distn. of the tar, a typical volumetric coal gas analysis, and a brief history of the development of gas manuf. and purification are given. The new Johannesburg Gas Works is described and the factors involved in its design and construction are discussed. The retort house contains 18 Glover West continuous vertical retorts of 25 ft. working length. The plant is designed to carbonize 100 tons of coal per 24 hrs., producing 1½ million cu. ft. of gas. Steam is injected on to the coke during its passages through the last 5 feet of the retorts; this results in an increase of 3000-5000 cu. ft. of gas per ton coal

carbonized. Sufficient steam for steaming the coke and for generating the mechanical and elec. power required to operate the machinery in the gas works is secured by passing the hot gases from the retort combustion chambers through "waste-heat" boilers. In this locality very few data are available for use in selecting suitable carbonizing coals. For this reason the plant was designed so that two of the retorts in the bench can be isolated from the main section of the carbonizing plant and be used as an expt. unit to test coals for the company's own use and also treat coals for test purposes for any of the coal mines. A no. of drawings and pictures show the lay-out of the gas works and of the different units constructed and machines installed. W. W. HODGE

Gas storage under high pressure, the spherical gas holder. D. STAVORINUS. Westergasfabriek, Amsterdam. *Het Gas* 48, 526-30(1928).—A review of Horton sphere holders as built by Klonne, Dortmund. Their pro and con (dry gas, illuminants condensation, etc.) are discussed. B. J. C. VAN DER HOEVEN

Dry quenching by the Sulzer process at the Oswald Street Gas Works, Burnley. J. HERBERT CLEGG. *Gas J.* 184, 785-90(1928). Plant, practice and results are described, with photographs and drawings. F. S. GRANGER

A study of comparative costs of gas production in the retort house. E. W. SMITH. *Gas J.* 184, 845-8(1928).—From a statistical comparison of continuous and intermittent vertical and horizontal retorts it is concluded that carbonizing conditions may be varied over wide limits without making any large difference in the final cost per therm. F. S. GRANGER

Gas works effluent. W. P. SMITH. *Gas J.* 181, 690-2(1928).—The subject is reviewed and discussed generally with reference to practical methods of prevention and cure of oxygen absorbing contamination, principally phenolic and thioevanate. The methods include minimizing time of contact between water and tar, or removal of the tar previously to aq. condensation, bacterial purification methods and dephenolation by distn. F. S. GRANGER

Gas purification by activated carbon and recovery of sulfur in the solid form. 1928 Report of the Comm. on Gas Mfr. of the Assoc. Technique. *Gas J.* 184, 526-7(1928). 1 G installations at Recklinghausen, Germany, are described. H_2S is adsorbed by the C at 35° and oxidized to S by admitting the proper quantity of air, through the catalytic action of the residual NH_3 in the gas after passing the scrubbers. The S is extd. by $(NH_4)_2S$ soln. and recovered by boiling. The C is revived by steaming and is originally obtained from lignite coke activated by steam at 900° . F. S. G.

The new plant for carbureted coke gas of the Westergasfabriek at Amsterdam. J. A. MOUL. *Het Gas* 48, 514-21, 533-40(1928). The 2 new Julius Pintsch water-gas sets are described. The generator of internal diam. 2600 mm, external diam. 3630 mm. is jacketed, steam of 1 to 2 atm. being produced (1300 kg. per hr.); the centric conical revolving grate has a dry seal with steam packing; grate and supporting platform with 2 clinker breakers are carried by rollers and driven at variable speed by a 5 h.-p. motor. The slag is removed from the grate table by baffles and drops into two boxes, emptied every 4 hrs. A Ruths steam accumulator of 13.5 cu. m. water capacity, 138 kg. steam between 4.1 and 0.6 atm. is provided; the steam used in the generator is superheated in a jacket surrounding the gas line between superheater and scrubber (heating surface 57 sq. m.). Steam connections in a ring around the charging hole take care of the down-run. The carbureter is cylindrical, 2700 \times 7400 mm., 37 cm. brick lining and 8.5 cm. slag wool; it is filled with staggered checkerbrick. The superheater is 2700 \times 7000 mm., lined as the carbureter and filled with brick; secondary air can enter at the bottom and halfway up. The gases can leave either through a blowoff or through the waste-heat boiler. The scrubber cools the gas partly. The final cooling is done in a Pintsch intensive indirect cooler of 8 sections with a total of 400 horizontal water pipes, surface 384 sq. m. The waste-heat boiler, horizontal fire-tube, is for 12 atm., and has 200 sq. m. heating surface. All large valves are moved by oil pressure of 13 atm., with differential plungers, and the necessary interlocks. Hand operation is used only for the secondary-air valves. During the 24-hr. guaranty test the actual results obtained were as follows: Gas produced 46,770 cu. m. of 4500 Cals., coke used 29,587 kg., oil per cu. m. gas 288 g., steam produced 28,993 kg. of 8.5 atm. in the waste heat boiler, 31,307 kg. in the jacket, av. clinker time 18 mins., blower consumption 616 kw. hrs. The coke weighed 48 kg. per hl. and contained 5.39% moisture, 9.83% ash and 84.78% C; the oil had d. 0.863; the carbureter temp. was 742° ; the av. gas analysis was 3.7% CO_2 , 7.2% illuminant, 0.5% O_2 , 34.7% CO , 12.2% CH_4 , 31.6% H_2 , 9.4% N_2 . The rather high coke consumption per cu. m. gas, guaranty was 60 kg., actual 63.1 kg., is due to unexpectedly high steam production in the jacket. A few drawings are given. There are no operation details. B. J. C. VAN DER HOEVEN

A source of error in the carbon balance (when gasifying fuel). WEHRMANN. *Gas u. Wasserfach* 71, 1253(1928).—In testing the efficiency of gas producers and generators, the C balance from gas analysis and orifice meter measurements gives high results for percentage efficiency, because of absorption of CO_2 in the washer cooler, the aspirator and in the gas buret. In one series of exts., the gas from the generator contained 4.95% CO_2 and only 4.40% was found by analysis. A correction of 0.6 to 0.7% should be added to results of analyses. This figure should be checked for each series of runs.

R. W. RYAN

Low-temperature tar products. A complex mixture. G. T. MORGAN. *Times Trade and Eng. Supplement* (London) 23, 29(1928).—A concise review. E. M. S.

Causes and reduction of the water content of tar. K. BUNTE. *Gas u. Wasserfach* 72, 1-3(1929).—Tar viscosity decreases with increase of temp., facilitating the sepn. of water from tar. In one tar almost no water sepd. out at 25°, but at 70° almost 98% sepd. out. The sp. gr. of both tar and gas liquor are important factors as very light tar and very heavy gas liquor can only be sepd. with difficulty. The sp. gr. of gas liquor and tar are dependent on temp. of carbonization, type of coal and moisture in coal and methods of cooling. Tar wells should be large and deep. The relative changes of sp. gr. of liquor and tar with temp. vary with different tars. Tar sepd. at various stages should be led to a common well. "Free carbon" may act as an emulsifier. Lower phenols may act as solvent for the higher tar acids, increasing the difficulty of sepg. tar and liquor. Ammonia-phenol soaps and other obscure emulsifiers may also hinder sepn.

Recommended specifications for quicklime for use in the distillation of ammonia from ammonia liquors obtained in coke and gas manufacture. ANON. Bur. Standards, *Circ. No. 373*, 4 pp.(1928).

E. J. C

Treatment of ammonia water from coke ovens. V. T. POSTOLOVSKII. *J. Chem. Ind. (Moscow)* 5, 992-7(1928).—To obtain ammonia for contact oxidation from the ammoniacal water of coke ovens, the method which consists in using low-pressure dissociators for the removal of CO_2 and H_2S , followed by concn. and purification, is expensive and wasteful, as it involves concn. of very dil. solns. The method which consists in washing the gases with lime water is also unsatisfactory, since the introduction in the column of dilute milk of lime, which must be not stronger than 5° Bé, naturally affects the heat balance of the system, and moreover dilutes the ammonia. Attempts to increase the concn. of the lime water have hitherto been unsuccessful, as they always led to the deposition of residues which required frequent taking apart of the column for cleaning purposes. The formation of deposits in the lime water is due to the following causes: penetration of suspended particles of sand into the column, absence of intensive stirring of the solid particles, insufficient dynamic effect of evaporating gases and water vapor. P. shows, by drawings of proper app. and calcus., that these difficulties can be overcome. Calcus. of the heat balance are also given.

Standards adopted by the "Bureau of the All-Russian Thermo-Technical Congress." V. P. FEDOROV, G. N. BEZRADETSKII, P. N. MAYEVSKII, T. A. ZIKEYEV AND A. A. NADEZH DIN. *Izvestiya Teplolekhn. Inst. (Trans. Thermo-Tech. Inst. (Russia))* 1928, No. 8, 60-132.—There are included provisional standards for coke ovens, instructions for detg. the heat balance of coke ovens, instructions for calcg. the consumption and distribution of gas, instructions for calcg. the elementary compn. of coking products, instructions for calcg. the heat balance of coke ovens, temporary instructions for measuring gas with Brabbe and Prandtl tubes, instructions for the detn. of the av. flow of gases in pipe lines, instructions for the measurement of the gas flow with diaphragms, standards for the physical-chemical constants of products obtained from coking, temporary instructions for sampling coal in testing coke ovens, temporary instructions for sampling coke of various sizes to det. the H_2O content and for general analytical purposes in testing coke ovens, instructions for sampling coke for the tumbling test in a drum and for making the test.

A. A. BOEHTLINGK

A method for the exact determination of the absorptivity of brown-coal semi-coke against air, steam and gases. M. DOLCH AND K. GIESELER. Universitätsinstitut f. tech. Ch., Halle a. d. S. *Braunkohle* 27, 1025-30, 1051-5(1928).—The detn. of absorptivity of a semi-coke toward gases, especially air, can yield correct or even comparable values only if the sample, directly after carbonization, is cooled and kept in a vacuum until tested. Otherwise it becomes partially satd. to an extent that differs with different specimens. An app. meeting these requirements is described. The absorptivity rises rapidly with the temp. of carbonization, but is decreased if the cooled coke is satd. with air and reheated. Predrying of the raw coal, in contact with O_2 , showed no influence on the reactivity of the semi-coke. Titrimetric results are reported indicating the possibility of distinguishing between adsorption and chem. combination by detg. the loosely combined I, on the one hand, and, on the other, the closely or chemically combined I which can be removed only by an alkali fusion. F. S. GRANGER

Coking coals and the coking process. P. DAMM. *Brenstoff-Chem.* 9, 293-5 (1928).—Coking properties of 6 German coals are studied. Bitumens are extd. by the Fischer method (*C. A.* 21, 814); caking power is detd. by the Meurice method (involving strength of coked mixts. of coal with sand); free expansion and pressure exerted by the coking charge are estd.; softening temp. is also detd. together with relative amts. of volatile matter evolved before, during and after passage of the charge through the plastic state. D. concludes that extn. results do not give complete information on coking properties, but finds that the more "oily" the bitumen found, the higher the strength of coke produced. Other conclusions are: The higher the caking power, the higher the coking pressure and the denser the coke; sticking in the coke oven is due more to lack of shrinkage after coke formation than to pressure exerted during formation; the more volatile evolved after formation, the greater this shrinkage; a good coking coal will have not only sufficient coking material to cause melting but it will also exert a certain coking pressure. Pressures found for the 6 coking coals varied from 0.0 to 0.7 kg. per sq. cm. The last would correspond in a coke oven to 7 tons per sq. m. of wall surface. J. D. DAVIS

The dry quenching of coke. D. W. WILSON. Dry Quenching Equipment Corp., N. Y. *Gas J.* 184, 792-4(1928); cf. *C. A.* 23, 957.—The Sulzer process, the only one com. successful in the U. S., is described and its advantages, as shown by data from an installation at Rochester, N. Y., are discussed. F. S. GRANGER

Use of pulverized fuel in metallurgical furnaces (BLYTHE) 9. Behavior of lignin in the natural decomposition of plants (FISCHER, LIESKE) 11A. The importance of H (HARKER) 18. Liquid fuel comprising carbonaceous material suspended in oil. AMERICAN COALINON CORP. Brit. 292,673, March 22, 1927. In processes such as those described in Brit. 149,306 (*C. A.* 15, 431), Brit. 154,605 (*C. A.* 15, 1207), Brit. 160,754 (*C. A.* 15, 2351) and Brit. 165,423 (*C. A.* 16, 484), the oils are thickened to the required consistency (before or after admixt. with the powdered fuel) by oxidation with air.

Oil fuel. JOHN E. HACKFORD. Fr. 643,229, Oct. 29, 1927. Oil is burned by causing a regular current of air to sweep without deflection across a continuously renewed layer or film of oil of about 5 to 7 1/2 cm. width.

Fuel for internal-combustion engines or turbines. R. PAWLIKOWSKI. Brit. 292,116, June 14, 1927. Powdered fuels contain 2 portions, one of which ignites more readily than the other, one portion either being more finely ground or drier or formed of

different material. Among the materials specified are: anthracite, coke residues, peat, powdered wood, fallen leaves or animal carcasses, lignite dust, ash-free coal dust, powdered C_1H_8 , $C_{14}H_{10}$ or sugar.

Fuel for internal-combustion engines. LESTER KIRSCHBRAUN. U. S. 1,701,620, Feb. 12. An emulsion is formed comprising pressure distillate from the cracking of hydrocarbon oils, water and naphthenic acid. U. S. 1,701,621 specifies a fuel comprising an emulsion of hydrocarbon oil and water, cut back with hydrocarbon oil contg. an oil-sol. emulsifying agent such as a naphthenic acid or sulfonic deriv. capable of being expelled from the engine without leaving any substantial residue; the initial emulsion is in the dispersed phase and the oil in the continuous phase.

Combustible fuel emulsion. LESTER KIRSCHBRAUN, HENRY J. ROSSBACHER and GENE ABSON (all to Kirschbraun). U. S. 1,701,622, Feb. 12. An emulsion gel for diln with a hydrocarbon oil is prep'd. by mixing a hydrocarbon oil such as gasoline with a sulfonic acid such as obtained in refining petroleum, and gradually adding and incorporating water in the mixt. to form a gel contg. the water in colloidal suspension.

Fuel briquets. H. LIESENS. Brit. 292,927, June 25, 1927. See Fr. 637,396 (C. A. 23, 501).

Binder for fuel briquets. O. REYNARD and F. F. TAPPING. Brit. 293,135, April 4, 1927. Sulfite cellulose waste liquor is used with bituminous material such as coal-tar pitch, asphaltic pitch or natural bitumen after neutralization of the liquor by NaOH or other alkali and is formed into a paste with finely divided coal, peat, lignite or the like, under pressure and while heated to above 100° . Various other materials such as oils may be added. Brit. 293,136 describes the production of briquets with bituminous binders together with oils and aq. emulsifying agents such as alkali or NH_3 salts or hydroxides or a caseinate, alginate, pectate, tannate, gelatin, glue or acid or neutralized sulfite cellulose liquor or suspensions of cereal materials or potatoes or beets, marine algae, etc.

Carbonizing fuel. HENRI BREUILLÉ and PIERRE BREUILLÉ. Fr. 643,543, April 9, 1927. Fuel is carbonized in compartments in the periphery of a horizontal or slightly inclined tubular furnace, in a chamber heated by the flames from a gas producer, and is stirred in its movement toward the discharging end. The gas products are evacuated as formed in the hollow core of the furnace, and the semi-coke formed is used for heating the gas producer placed immediately below.

Retort (of inverted pear shape) for carbonizing pulverulent fuel in vortical movement. J. N. BAILEY and METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Brit. 293,106, March 29, 1927.

Continuous-working fuel distillation plant with rotary cylinder. EDMUND ROSER. Ger. 469,898, July 7, 1925.

Coal dust fuel plant for annular kilns. CARL ROST. Ger. 470,223, Nov. 25, 1925. Details of arrangement are given.

Hydrogenation. SOCIÉTÉ INTERNATIONALE DES COMBUSTIBLES LIQUIDES. Fr. 33,112, Mar. 5, 1927. Addn. to 618,490. In a process for the hydrogenation of coal, oil, etc., in which a hydrogenated hydrocarbon such as $C_{14}H_{10}$ is added to the crude material, the mixt. of products obtained is brought to a temp. higher than that of the main process, whereby the hydrocarbon is reformed and a further hydrogenation of the products from the crude material takes place.

Hydrogenation of coal. LINDELL T. BATES. Fr. 643,399, Nov. 5, 1927. A liquid fuel is obtained by submitting coal and H to friction and mech. shocks, e. g., in a grinder of the mol. type. The heat liberated by the grinding is used to raise the temp. of the reagents, and the pressure of the H is without importance.

Distillation of coal. FRIEDRICH SENTKE and LUDWIG WACHTER. Ger. 470,216, Mar. 20, 1926. A pressure door for a coking furnace is described.

Suspensions or pastes of coal. I. G. FARBENIND. A. G. Brit. 292,217, Mar. 11, 1927. Finely ground coal is dispersed in alcs. (suitably MeOH or iso-Bu alc.) to which are added basic substances sol. in the alc. such as alkali metal hydroxides, NH_3 , methylamine, pyridine or aniline. Small proportions of mineral oil also may be added and this may be an oil contg. finely divided C such as crude petroleum or brown coal tar oils. The product may be used as a raw material in destructive hydrogenation.

Apparatus (with a reciprocating, air-pervious table) for separating coal from impurities, etc. K. DAVIS (to R. Peale, W. S. Davies and W. S. Wallace). Brit. 292,495, June 20, 1927.

Removing water from peat. G. A. SCHROTER. Brit. 292,661, March 18, 1927. Peat slurry is treated with an alk. coagulating agent such as $Ca(OH)_2$ and liquid is removed by filtering or decanting; dried peat or fiber is added and there may also

be added about 1% of a drying agent such as burnt lime and the mass may be compressed and allowed to dry; a product with less than 10% of water may be thus obtained.

Montan wax. I. G. FARBERIND. A.-G. Brit. 292,298, April 8, 1927. Hot concd. HOAc is used for purifying montan wax which may be previously bleached and deresinified. Glacial HOAc may be used in a Soxhlet app. and various details are given. Cf. C. A. 23, 1253.

Gas from fuel. BAMAG-MEGUIN A.-G. and OSWALD HELLER. Ger. 470,275, April 2, 1926. See Brit. 268,745 (C. A. 22, 1461).

Flue gas. IWAN D. KOSTIN. Fr. 643,440, Nov. 7, 1927. Steam is added to flue gas and condensed again, whereby particles of coal, etc., and harmful gases such as SO_2 are removed.

Water gas. CHARLES W. ANDREWS and HERMAN A. BRASSERT. U. S. 1,701,253, Feb. 5. A mass of carbonaceous residue such as coke is air-blasted to raise its temp., a layer of coal is placed on the residue, steam is passed through the residue to form blue water gas and the heated blue water gas is passed through the coal so that its heat serves to volatilize the volatile matter of the coal; the layer of coal is agitated during the passage of the blue water gas, and the process is continued by alternately air-blasting and then adding coal and passing steam through the residue (the blue water gas passing through the added coal); and the blast air and steam are both preheated by heat derived from the air-blast gases. An app. is described. Cf. C. A. 22, 2656.

Water gas. FRANZ SCHÜSSL. Ger. 470,328, Dec. 3, 1927. The heat accumulator is made up of vertical plates which are sprinkled with water to form the steam.

Water-gas generator. H. S. MOORE and W. S. MOORE. Brit. 292,408, Nov. 10, 1927. The blow gases pass through twin superposed annular recuperative checkered heating chambers surrounding a preliminary distn. retort; each tier of the chamber is divided by vertical division walls into 2 sep. compartments through which the hot blow gases travel, and the 2 sets of chambers are used for carbureting the gas with gas oil or the like. Various structural details are described.

Plant for producing water gas and distillation gas. REGENERATIVE COAL GASIFICATION SYSTEM, LTD., and M. W. TRAVERS. Brit. 292,410, Nov. 11, 1927. A plant as described in Brit. 210,356 is modified by arranging the carbureting chamber in series with the regenerating chamber, so that the whole of the blow gases passes from the regenerating chamber through the carbureting chamber and then through a super-heating chamber.

Coal gas and water gas plant. T. F. CANNING and R. G. CLARK. Brit. 292,235, March 15, 1927. The specified plant comprises a plurality of horizontal or inclined retorts which discharge into a vertical chamber and a producer for supplying gas for heating the exterior of the retorts and chamber under independent control; gases from the chamber are continuously conducted into the retorts. O, air or inert gas may be blown into the chamber through nozzles and connections are provided for supply of superheated steam and oil for carbureting the water gas. Various structural details are described.

Gas producer. IVO SCHWARTZ-ARNYASY. Ger. 469,880, Mar. 12, 1925. The gasifying agent is caused to pass through the fuel descending in zig-zag fashion through the producer.

Gas producer. ANDRÉ LIÉTARD. Fr. 33,177, Oct. 28, 1926. Addn. to 631,717.

Apparatus for controlling the supply of moisture to a gas producer. THE GAS RESEARCH CO. Ger. 469,787, Nov. 15, 1922.

Gas purification. WILLIAM H. HILL and DAVID L. JACOBSON (to Koppers Co.). U. S. 1,700,982, Feb. 5. Humic acid is used to accelerate reactions such as regenerating, by aeration, the Fe sulfide formed in gas purification.

Gas purification. SOC. ANON. LA CARBONITE. Ger. 470,232, Nov. 30, 1927. App. for sepg. and collecting condensable vapor from the gases distd. from wood and peat has a center column contg. a conical rotating member carrying receptacles for the condensate.

Purifying gas. WALTER H. FULWEILER (to U. G. I. Contracting Co.). U. S. 1,700,698, Jan. 29. In using a soln. of a salt such as Na_2CO_3 sufficiently alk. to absorb H_2S as sulfhydrate and thereby rendering the soln. foul but without formation of Fe sulfide, the sulfhydrate is oxidized by passing air through the fouled soln. to form S and regenerate most of the salt used for the gas purification. An arrangement of app. is described. Cf. C. A. 22, 3763.

Purification of gases. THE KOPPERS CO. Ger. 469,021, Mar. 15, 1923. H_2S and other gaseous impurities are removed from gases by treatment with an alk. soln. such

as a soln. of Na_2CO_3 . The soln. may contain in suspension a little freshly prepd. Fe_2O_3 , or a pptd. metallic salt, such as FeSO_4 . Cf. C. A. 23, 961.

Separating hydrogen sulfide and ammonia from gases. I. G. FARBENIND. A.-G. Brit. 292,669, March 21, 1927. In treating coke-oven gases, illuminating gases and the like with solns. such as polythionates, thiosulfates contg. SO_2 , or sulfite-bisulfite solns., a portion of the NH_3 is first sep'd. (suitably as an aq. condensate by cooling the gas) and is added in the latter stages of the washing operations. NH_3 from an external source also may be used. Various details and modifications of procedure are described.

Removing hydrogen sulfide and like impurities from gas. GILBERT E. SEIL (to Koppers Co.). U. S. 1,701,825, Feb. 12. The gas is subjected to the action of bacteria such as *Thiobacillus thioparus* which have the ability to oxidize the impurities. The treatment may be suitably effected in a counter-current app. which is described.

Ascertaining the volumetric proportion of a constituent such as carbon dioxide in combustion gases. HORACE N. PACKARD and EDWIN X. SCHMIDT (to Cutler Hammer Mfg. Co.). U. S. 1,700,852, Feb. 5. Portions of a fluid such as combustion gases are introduced into receptacles of normally equal capacity, before and after removal of a constituent such as CO_2 , and the relative capacities of the receptacles are regulated to maintain equal measurement pressures in them irrespective of variations in proportion of the constituent and a device is provided for continuously indicating the proportion of CO_2 . An app. is described.

Metal parts of gas holders. T. V. MILES and NEWTON, CHAMBERS & Co., LTD. Brit. 292,861, Jan. 3, 1928. Plates, girders, bars, etc., which are subject to corrosion are made from an iron or steel alloy contg. Cu 0.1-3.5%.

Gas holder with a compartment filled with inert gas. H. NIELSEN and B. LAING. Brit. 293,098, March 28, 1927. The inert gas may be heated or mixed with heated gases to prevent the tar seal from thickening in cold weather.

Supplying steam to vertical gas retorts, coke ovens, chemical and tar plants, etc. A. COE. Brit. 293,160, May 14, 1927. A construction is described in which a throttling device is provided for each retort and an indicator shows whether a proper quantity of steam is being supplied.

Coking. C. OTTO & Co. G. M. B. H. Ger. 470,176, June 3, 1925. A coke furnace with vertical heating chambers is given a recurring sequence of 4 heatings.

Coking. C. OTTO & Co. G. M. B. H. Ger. 470,315, Mar. 4, 1928. Addn. to Ger. 454,016. The distd. gases of a vertical chamber furnace are led back to cool the hot coke and are then led to the hot part of the furnace for reheating.

Coke for use in reduction furnaces. P. L. J. MIGUET. Brit. 292,931, June 25, 1927. Fumes and dust from reduction furnaces are mixed with fines of coking coal and the mixt. is coked and used in the reduction furnaces.

Coke for ore smelting. F. HOFMANN. Brit. 293,109, March 29, 1927. Coked coal is briquetted while heated and then converted into semi-coke.

Apparatus for cooling and loading coke coming from the retorts. C. OTTO & Co. G. M. B. H. Fr. 643,320, Nov. 3, 1927.

Coke furnaces. FOUNDATION OVEN CORP. Fr. 643,110, Oct. 8, 1927. To obtain uniform heating in coke furnaces in which the retorts narrow from the pusher the bottom of the furnace comprises a series of openings varying in size according to their position and following the charge to be converted.

Vertical coke oven construction. BAMAG MEGUIN A.-G. Brit. 292,539, June 21, 1927.

Recovery of heat from coke. FRANKFURTER GASGESELLSCHAFT, PAUL F. TILLMETZ and ERNST SCHUMACHER. Fr. 642,865, Oct. 13, 1927. The heat from incandescent coke from retorts or coke furnaces is recovered by inert gases in 3 distinct stages

22--PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

F. M. ROGERS

Petroleum refining and cracking. Renewed interest in vapor-phase method. A. E. DUNSTAN. *Times Trade and Eng. Supplement* (London) 23, 30-1(1928).—The Gyro, Knox, Leamon and Gray processes are reviewed briefly. In the latter process the vapors pass through a column of heated fuller's earth, removing polymerizable hydrocarbons as a heavy gum capable of use in varnishes and lacquers. The fuller's earth is cleaned by periodical flushing by solvent. The outstanding feature in recent

developments is the increase in use of continuous app., reducing fire risk and vapor losses. In lubricating oils replacement of NaOH by various clays in refining continues to gain. Cracked oil gases contain C_2H_4 , C_2H_6 , C_4H_8 , C_4H_{10} and 1% butadiene, the latter increasing at higher temp. Isopropyl and butyl alc. are produced today, the former finding use as an antiseptic.

E. M. SYMMES

Modern cracking process greatly increases production. G. EGLOFF. *Intern. Fuel Conference* (London) 1928, Paper No. F-12; *Fuels & Furnaces* 6, 1719-21(1928).—The yield of gasoline obtainable from crude oil by simple distn. can be more than doubled by cracking. Gasoline produced by cracking is preferred because of its content of olefin, naphthene and aromatic hydrocarbons, which give it marked anti-knock qualities. Of 15,000,000 gal. of gasoline produced in 1927, 4,000,000 gal. was produced by cracking. Cracking may be of the residual-oil type, the products being gasoline, furnace or Diesel oil, a high-grade fuel oil and gas, or it may be of the non-residual-oil type, the products being gasoline, furnace or Diesel oil, gas and coke. The present-day cracking process is flexible enough to be adaptable to any type of charging stock. Possibilities of cracking low-temp. tar, shale oil, wood tar and vegetable oils are mentioned.

D. F. BROWN

Deparaffining Grozny mazout. ANON. *Neftyanoe Khozyaistvo* 1928, No. 12, 102.—Grozny mazout freezing at 40° was cracked in a tube still at atm. pressure, yielding 2-3% gasoline, whereby the f. p. was decreased by 10° . This light cracking was carried out with the intention of lowering the f. p. of mazout, which is very difficult to handle. The expts. are being continued.

A. A. BOEHLINGK

The spontaneous decomposition reaction of the Bergius process. A reaction common to certain hydrocarbons. EVALD PHYALA. *Tekniska Föreningens i Finland Förhandlingar* 48, 221-6(1928).—Studies were made on the distillation of certain oils from the Baku region with a high paraffin content. A special column was used which made possible a slow heating, thereby providing for a delicate control. The first cracking begins at 380° to 410° , and the second at 410° to 450° . The products are gases, and benzine and kerosene fractions. The process can be applied to naphtha residues with a high f. p., which can thereby be converted into liquid fuels. It is also suggested that it might be applied to the tars obtained in turpentine distns., as well as to used oils from transformers and the like. It is further suggested that the liquefaction of coal in the Bergius process is due to a similar cracking of the hydrocarbons in the coal. Hence, carbonized material such as wood charcoal, coke, or peat coke cannot be liquefied.

HANS C. DUUS

Drying of oil transformers. L. SCHÄTZ. *A E G-Mitt.* 1929, 37-8.—In the A E G process the oil as received from the refinery is dried with nitrogen. The oil is placed in a vacuum tank equipped with a circulating pump, and N from a liquid-air plant is blown into the high-pressure side of the circulating line. When the oil gets back into the vacuum tank the N bubbles expand, and the water distils into them. The wet N is pumped off. When test shows that the resistance has become const. the oil is removed, with the same quality as it had originally. The old process involved heat, and caused the oil to darken, and to increase in acid and tar numbers. To preserve the quality of the oil, the transformer core and windings are thoroughly dried and cooled before the oil is added. The removal of air bubbles by prolonged vacuum treatment completes the process. Transformers so dried need no further treatment in the field, and the oil retains its quality.

BENJAMIN MILLER

The adaptability of cold emulsions. With some simple tests. F. W. VALLÉ-JONES. *Munic. Eng. Sanit. Record* 81, 623(1928).—Advantages and suggested uses of cold bitumen emulsions are given. The tests mentioned are the blotting paper test for moisture content; drying on glass rods to compare thickness, adhesiveness, and tackiness, and detg. with the thumb and index finger the ductility after drying.

C. H. BADGER

Continuous treatment of kerosene. YU. BOGOSLOVSKII. *Neftyanoe Khozyaistvo* 1928, No. 12, 33-7.—The treating method introduced by G. Ya. Torosyan is based on the counter-current principle. A closed container with a conical bottom is charged continuously with kerosene distillate through a pipe connected through the wall on the lower part; the sulfuric acid is admitted through a pipe terminating close to the inlet pipe for kerosene inside of the container, the mixt. being agitated with air. The treated kerosene is displaced gradually by fresh distillate and leaves the agitator to enter an open tank divided by a partition into two parts. The partition reaches the bottom but leaves at the top free space for the kerosene to flow over into the second part; the air bubbles are thus liberated. The kerosene enters further a set of four closed settling tanks arranged in parallel. Special attention must be paid to this part

of the procedure, where most of the suspended sludge has to ppt.; when this is carried out properly it simplifies the following operations, assuring at the same time a good final product. The sludge is continuously withdrawn through the bottom, the kerosene through the top. A caustic treatment in the next container, a settling operation and a second caustic treatment are made, giving finally a product of 0.8180-0.820 sp. gr., 28.5-32.0° flash and 210-300 mm. color (Stammer scale). The treatment requires 0.38-0.35% of H_2SO_4 and 0.11-0.12% caustic (calcd. on solid NaOH). The distillates treated contained 0.44-0.46% naphthenic acids (from Balakhanui crude) and 0.24-0.27% naphthenic acids (from Surakhanui crude). A. A. BOEHTLINGK

Effect of anti-knock materials on the speed of initial uniform movement of the flame in hydrocarbon-air mixtures. YŪZABURŌ NAGAI. Tokyo Imp. Univ. *Proc. Imp. Acad.* 4, 525-8(1928).—The effect of SeEt_2 , SnMe_4 , and PbMe_4 on the speed of initial uniform movement of the flame in a mixt. of air and hydrocarbon vapor has been studied. The hydrocarbon consisted of a mixt. of about 43% dimethylcyclopentane and 57% isoheptane. The speeds of the initial uniform movement of the flame are distinctly lowered by the addn. of the anti-knock materials, the speed-concn. (of hydrocarbon) curve being lowered more and more with the increase in concn. of the anti-knock materials. When the concn. of SnMe_4 or PbMe_4 reaches 1%, the curve is not lowered by further addn. of these compds.; the concn. of SeEt_2 to produce the same result is about 2%. C. J. WEST

Improvements in the separation of naphthenic soaps. V. SHIPEROVICH AND V. GURVICH. *Neftyanoe Khozyaistvo* 1928, No. 12, 26-33.—The kerosene alkali sludge contains 10-25% of naphthenic soaps, depending on its origin and the amount of caustic used in the neutralization process. Two vertical towers (old boilers could be used) have the upper part equipped for burning gas and the lower for evapg. the water from the sludge through the heat generated by above gas burners kept at the required temp. by admission of additional air. The sludge enters the upper part of the first tower, where it is atomized and mixed with the burning gas, losing 25-40% of its water. The concentrate leaves through the bottom, is collected in a receiver and sent through the second tower of identical construction and is finally concd. to 40% in naphthenic acids, which are then salted out. A fan is provided to create the draft needed to move the burning gases and steam. Various calcns. such as heat calcn., gas consumption, etc., are given. A. A. BOEHTLINGK

Lubricating oil and lubrication. WALTER VOGL. *Oesterr. Chem.-Ztg.* 31, 211-2 (1928).—Many useful formulas are available when lubrication is complete, but the exact specification of an oil where the lubrication is only partial and where there are great variations in pressure and temp. is not practicable at present. E. C. B.

New high vacuum distillation plant for lubricating oils of the "Azneft." B. VLAŠENKO. *Neftyanoe Khozyaistvo* 1928, No. 12, 50-70.—Mazout preheated by the bottoms from the last still in two heat exchangers enters the first vacuum shell still, the stripped oil passing gradually all 20 stills by gravity, the last ones being arranged in cascades with approx. 13-cm. drop. The oil having a temp. of 150° in the first still is gradually heated up to 360° in the last still. The stills are provided each with 4 dephlegmators arranged in series; the last is connected with a barometric water spray condenser (the use of this condenser can be discontinued if necessary). Each dephlegmator has an air-cooled condenser attached to the bottom connecting a barometric tube through which the oil cut is withdrawn (80 cuts are obtained). The last dephlegmators (from each still) have a connection with the main vacuum line which terminates in a surface condenser with 360 brass pipes cooled by water and condensing the steam and oil vapors, the gases pass then through a barometric water-jet condenser and a water-jet vacuum pump. A vacuum of 250-300 mm. Hg is maintained in the stills and the steam used for carrying the oil vapors is superheated to 250°. The capacity of this plant is 850-870 metric tons of oil in 24 hrs. Very complete data on all parts of the equipment are given, including the strength of still shells, diam. of piping, etc. A. A. BOEHTLINGK

The alundum crucible in the determination of carbon in crankcase oil. PAUL V. MCKINNEY. *Chemist-Analyst* 18, 21(1929).—The C residue of an oil as detd. by the Conradson method has little relation to the amt. of residue accumulated in the crankcase of an automobile. Difficulty encountered in filtration of this residue can be overcome by using an alundum crucible. If water has been detd. in the oil, use the residue remaining in the flask. Otherwise take 10 g. of the oil and 100 g. of light petroleum ether. Filter through an alundum crucible, wash with 25 cc. of the ether, dry, weigh, ignite and weigh again. W. T. H.

Wood distillation. Modern charcoal burning. K. S. C. BONE. *Times*

and Eng. Supplement (London) 23, 30(1928).—Small waste wood from woodworking factories is satisfactorily carbonized in thin layers in continuous retorts, giving the usual volatile products and flake charcoal for the manuf. of black powder, NaCN, KCN and insulation. This process is used only in England. The Suida process for direct extrn. of 98% HOAc from crude pyroligneous acid is receiving close attention.

E. M. SYMMES

Bacterial oxidation of crude oils (TAUSON) 11C. Manipulation of the Engler viscometer (ERK) 2. Naphthenic acids. VIII. Polymethylene rings of naphthenic acids in Japanese petroleum (KUWATA) 10. Device for gravity separation of oil from water, etc. (Brit. pat. 293,091) 1. Colloidal dispersions (Brit. pat. 292,965) 13. Treating gasoline, etc., to prevent evaporation losses (U. S. pat. 1,701,870) 13. Filtering material (U. S. pat. 1,702,104) 18. Separation of solids from liquids (Fr. pat. 643,693) 13. Emulsifying agents and emulsions (Fr. pat. 33,278) 13. Chloronaphthalene (Fr. pat. 642,681) 10. Washing benzene, alcohol, etc. (Fr. pat. 643,500) 13.

Petroleum oils. FRANK BUREAU. Fr. 642,674, Mar. 22, 1927. Paraffin is removed from petroleum oils by submitting the oil, preferably dild. with gasoline, to a refrigeration which ppts. the paraffin and afterwards filtering through ultra-filters.

Refining petroleum oils. F. HOFMANN and W. STEGEMANN. Brit. 292,932, June 25, 1927. Gaseous or liquid HF, with or without addition of metal halides, is used. Brit. 292,933 specifies a similar process for refining oils derived from coal.

Breaking up crude petroleum emulsions. SAMUEL W. COLE. U. S. 1,700,627, Jan. 29. Metallic Na and CaC₂ are added to effect reaction with the water present and sepn. of oil and water into layers.

Petroleum still. ARTHUR E. PEW, JR. (to Sun Oil Co.). U. S. 1,700,709, Jan. 29. Oil is supplied to an inclined vaporizing pan within a still and a reticulated cover is placed over this pan to restrict foaming.

Hydrocarbons from bituminous sand. COMPAGNIE MINIERE DES PETROLES DE MADAGASCAR. Fr. 643,514, Apr. 7, 1927. Hydrocarbons are extd. from bituminous sand or sandstone by treating the material, ground if necessary, to the action of a salt soln. of a density appreciably higher than that of the bitumen, the operation being carried out at about 100° with stirring. The material may be given a preliminary treatment with oil coming from a previous distn. of hydrocarbons already extd.

"Cracking" hydrocarbons. GASOLINE PRODUCTS CO., INC. Fr. 642,818, Sept. 9, 1927. See Brit. 290,996 (C. A. 23, 1260).

Cracking hydrocarbon oils. WALTER J. PERELIS (to Shell Development Co.). U. S. 1,701,477, Feb. 5. Feed stock is sepd. into more and less volatile fractions; the less volatile constituents are subjected to cracking and a heavier fraction is sepd. from the more volatile products of the cracking; this heavier fraction is mixed with a heavier fraction of the more volatile constituents of the feed stock and this mixt. is subjected to a sep. cracking. An arrangement of app. is described.

Treating hydrocarbon oils with decolorizing clay. FRANK W. HALL (to Texas Co.). U. S. 1,700,479, Jan. 29. Clay which becomes exhausted from treating light-colored oil is partially revived and then used for treating darker oil.

Lining cracking coil or condenser tubes, etc., for treating hydrocarbon oils. W. E. TRENT (to Trent Process Corp.). Brit. 292,535, June 21, 1927. A lining is formed of material such as porcelain, earthenware or a non-metallic paint or other material that has a selective affinity for water and thus causes the formation of a film of water, which prevents formation of C deposits.

Refining mineral oil. HENRY BLUMENBERG, JR. U. S. 1,700,347, Jan. 20. Mineral oil or its products such as "cracked gasoline" are treated with HCl and the latter is decomposed electrolytically in the presence of Al.

Vacuum distillation still for mineral oils, etc. HUGO REIK. Austrian 111,850. Aug. 15, 1928.

Carbonizing heavy oil residues. STANDARD OIL CO. OF IND. Brit. 293,231, Sept. 9, 1927. Heavy residues, such as those produced by distn. of petroleum oils to bottoms of 10%, or less the quantity of the original crude oil, are deposited as a coating on a nickeliferous or chromiferous surface and heated to drive off volatiles and leave a coke layer which is mechanically removed. Monel metal and other specified alloys may be used in making the app. (details of which are described).

Distilling apparatus for oil shale. MAGNUS R. KRAUL. Can. 286,216, Jan. 8, 1929.

Oil-shale retort. MAGNUS R. KRAUL. Can. 286,217, Jan. 8, 1929.

Oil gas. C. CHILOWSKY. Brit. 293,007, Oct. 27, 1926. In gasifying oils by atomization and partial combustion at a temp. above 600° and passage of the resulting products and excess vapors over a catalyst in a heated container, the feed of oil to the atomizer is periodically interrupted to allow the continuous supply of spraying air to remove C deposits by combustion. Superheated steam also may be added. Brit. 293,008 describes an app. for carrying out similar processes.

Apparatus for production of oil gas. FRANK T. NEWITT, SIMON H. LAPLANT and LEWIS I. TURNER (to L. T. N. Mfg. and Development Co.). U. S. 1,701,892, Feb. 12.

Purifying gasoline, etc. SILICA GEL CORP. Brit. 292,231, March 14, 1927. Gasoline and similar hydrocarbon oils are purified by passing them at an elevated temp. (suitably about 120° or higher) through an adsorbent with pores of such size that the material will absorb H₂O vapor to the extent of 21% or more of its own wt. when in equil. with H₂O vapor at 30° and a partial pressure of 22 mm. Hg. The adsorbent may be silica gel as described in Brit. 136,543 and Brit. 195,055 (C. A. 17, 3555) and it may be impregnated with metallic oxides such as those of Cu or Fe not exceeding 1% the wt. of the adsorbent and with about 5% H₂SO₄ to sep. gum-forming constituents. An arrangement of app. is described.

Apparatus for combining natural gas and hydrocarbon oil for the production of gasoline. LESTER S. WORTHINGTON (to C. L. Thompson). U. S. 1,700,556, Jan. 29.

Device for separating water and sediment from gasoline. DAVID SAMIRAN (one-half to Phillips Melville). U. S. 1,700,811, Feb. 5.

Emulsions. BERTHOLD REDLICH. Fr. 643,055, Oct. 27, 1927. Emulsions of substances such as oil in water are obtained by mixing the oil with a solid finely powder and purified substance with large absorptive properties such as SiO₂, clay, oxide of Fe, etc., and mixing with water. The solid material settles out, leaving a pure emulsion.

Bituminous emulsions. ASPHALT COLD MIX, LTD., F. LEVY and L. G. GABRIEL. Brit. 292,251, March 17, 1927. Material such as Mexican asphalt in molten or liquid form is treated with 2-5% of an emulsifying agent comprising fatty acid such as oleic acid and a dil. soln. of an alkali silicate or borate. Several examples are given, borax or Na perborate may be used.

Emulsifying tar, etc. WILFRED E. BILLINGHAM. U. S. 1,700,581, Jan. 29. In emulsifying tar, bitumen, creosote, petroleum and like materials, a concd. emulsion is first prepd. from a small quantity of the material and this is then used as an emulsifying material for emulsifying larger quantities of the same material.

Wire-drawing lubricant. CHARLES V. IREDELL (to The Canadian Westinghouse Co., Ltd.). Can. 286,472, Jan. 15, 1929. A wire-drawing lubricant consists of powder graphite suspended in a gelatinous medium composed of agar-agar boiled with water to a jelly-like consistency to which has been added 0.75-1.0% by vol. of Turkey red oil.

Regenerating lubricants such as those from marine or internal-combustion engines. SWAN, HUNTER & W. RICHARDSON, LTD., and H. J. YOUNG. Brit. 292,300, April 12, 1927. Used lubricating oils contg. corrosive impurities such as H₂SO₄ or metallic sulfates are regenerated by intimate contact with a non-ferrous metal or alloy which produces reaction products without the same deleterious effects. Zn, Al, Mg or their alloys with each other or with Na or Ca may be used. An app. is described.

Lubricating-oil rectifier suitable for use on internal-combustion engines. FRANK E. CARTER. U. S. 1,701,490, Feb. 12.

Filter for oils suitable for use in connection with automobile engines. CHARLES C. BLACKMORE. U. S. 1,701,556, Feb. 12.

Combined oil and air filter suitable for use on internal-combustion engines. WILLIAM C. DEWITT. U. S. 1,702,156, Feb. 12.

Purifying wood-distillation gases. EMIL PIRON (to Piron Coal Distillation Systems). U. S. 1,701,054, Feb. 5. Tar and tar-forming constituents are removed by washing with a soln. of H₂SO₄ while maintaining the temp. above the condensing point of the "nontar" vapors. An arrangement of app. is described.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Consideration of the change in colloid structure of natural cellulose by solution and ming. O. FAUST. *Kolloid Z.* 46, 329-36(1928).—Different theories of the colloidal structure of cellulose are mentioned and discussed. To bring cellulose into soln. it is

first necessary to change the cell structure as the compact natural product is insol. The ripening of cellulose in alkali is accompanied by a shortening of the cell and a decrease in particle size, making it more easily reacted upon. The increased soly. of cellulose xanthate is due to a deep-seated deorientation and deformation of the previously well oriented micelli. The increased hydration then gives the micelle a more spherical shape. Too marked a destruction of the bonds in the micelle detracts from the spinning quality of the artificial silk.

L. F. MAREK

The fundamental principles of rayon production. THOMAS F. HUGHES. *Textile Colorist* 51, 89-92(1929).—"A usable spinning solution," a fitting device or contrivance for forming and withdrawing the threads and gathering them after they have coagulated or hardened," and "a suitable coagulating medium for fixation of the filaments" are necessary for producing rayon properly.

RUBY K. WORNER

The behavior of nitrocellulose gels in polarized light (PHILLIPS) 2. The chemical industry in Sweden (ANON) 13. Negative catalysis in slow and induced reactions (DIAR) 2. Immunized and amidated cotton (TROTMAN) 25. Recovery of volatile products (Fr. pat. 643,322) 13. Carbonaceous product from electric furnace treatment of carbonized lignin residues (U. S. pat. 1,701,272) 18. Polysaccharide degradation (Can. pat. 286,179) 28. Drying rubber articles (Brit. pat. 293,061) 30. Recovery of dissolved or suspended substances (Fr. pat. 643,102) 13. Photometric apparatus for inspection and sorting of paper, cardboard, etc. (Brit. pat. 292,474) 1.

Cellulose. F. G. P. LEO. Brit. 293,219, Aug. 15, 1927. The sap of the banana plant is used in the obtainment of cellulose from materials such as bamboo, sugar cane or megass, maize straw and stalks, cereal straws, jute, linen, cahete, cana, tabua, reed, papyrus, banana fiber, *Hedychium coronarium*, stamens of palm leaves, woods and grasses. The banana sap is allowed to act for several days.

Cellulose. GESELLSCHAFT FÜR MECHANISCHE ZELLULOSE M. B. H. Fr. 33,145, Mar. 14, 1927. Addn. to 579,237. Freshly cut grasses, reeds, bamboo or waste from banana plants are cut into little pieces, ground dry in a mill, washed with water and ground in a hollander. The product is used for the manuf. of cellulose.

Cellulose. JOAQUIN JULIO DE LA ROZA, SR. Can. 286,198, Jan. 8, 1929. Vegetable fiber is treated with dil. H_2SO_4 soln., the liquor is sepd., and the fiber is stored for a period substantially longer than the period of treatment with the acid. The fiber is washed with hot water, and then treated with an alk. soln. (KOH or NaOH) at a temp. above 100° and a pressure above atm.

Cellulose from graminaceous plants. GIACOMO ROSSI and UMBERTO GENNARO. Fr. 633,384, Nov. 5, 1927. Cellulose and textile fibers are prepd. from graminaceous plants or, in general, those rich in SiO_2 , by removing the SiO_2 by a cold treatment with alkali, washing or neutralizing and submitting the plants thus treated to a microbiological and enzymic retting by a known method, e. g., by the action of aerobic pectic enzymes in a current of air.

Cellulose from wood. E. HAGGLUND. Brit. 292,534, June 21, 1927. In order to obtain cellulose of good strength and in good yield from woods such as pine and beech, they are boiled with alkali just long enough to sep. the fiber and then treated with Cl by which HCl and lignin chloride which is sol. in water and alkali are produced. "Chloride of lime" is then added and reaction effected with stirring and the material is washed with water and alkali. The treatment with Cl and hypochlorite may take place in stages.

Treatment of cellulose materials. ARNOLD PRINT WORKS. Fr. 642,819, Sept. 9, 1927. Cellulose materials such as cotton are impregnated with a NaOH soln., allowed to dry, and in the dry state are superficially treated either all over or in selected parts of its surface to produce a design, with a soln. of cuprammonium, which may be in the form of a paste contg. dissolved cellulose.

Saccharifying cellulose. COMMERCIAL ALCOHOL CO., LTD. Brit. 292,918, June 25, 1927. Cellulosic material is decomposed with strong acid (preferably HCl) and saccharified by aid of steam or mixts. of steam with inert gases. The preliminary decompn. with acid is effected at such a low temp. (preferably below 0°) that a premature sugar formation is avoided and the decomposed material is then passed into a saccharification vessel without contact with the atm. An app. is described. Brit. 292,919 also relates to a similar procedure in which HCl gas may be used after treating the material with HCl soln.

Preparing cellulose for nitration. GEORGE A. RICHTER, MILTON O. SCHUR and ROYAL H. RASCH (to Brown Co.). U. S. 1,701,543, Feb. 12. Fibers such as those

of alpha-cellulose wood fiber are coated with a cellulose deriv. (suitably nitrocellulose) and permeated with regenerated cellulose.

Nitrating cellulose. A. P. H. DESBOROUGH, W. T. THOMSON and R. S. G. KNIGHT. Brit. 293,190, June 24, 1927. Cellulosic material in sheet or layer form is passed onto a roll mounted over a shallow bath into which nitrating acid is fed at a rate corresponding to its rate of absorption. An app. is described.

Nitrocellulose. VICTOR PLANCHON. Fr. 643,454, Nov. 8, 1927. Wood pulp is nitrated in sheets placed astride parallel sticks and kept apart by projections formed by passing the sheets through a stamping machine.

Nitrocellulose. GEORGE A. RICHTER, MILTON O. SCHUR and ROYAL H. RASCH (to The Brown Co.). Can. 286,079, Jan. 1, 1929. Wood pulp high in α -cellulose is beaten to form nitration tissue, and this tissue is nitrated and dissolved in a nitrocellulose solvent. The tissue suitable for conversion into nitrocellulose possesses the following characteristics: α -cellulose content over 93%, "soda solubility" (in 7.14% NaOH) under 12%, copper number under 2.5, ash under 0.4%, resins under 0.4%.

Cellulosic composition suitable for nitration or other esterification. GEORGE A. RICHTER (to Brown Co.). U. S. 1,700,595, Jan. 29. Mercerized cellulose fiber carrying a deposit of regenerated cellulose is suitable for producing nitrocellulose of less than usual viscosity. U. S. 1,700,596 specifies a mixt. of mercerized and unmercerized fiber, which is also suitable for similar use.

Cellulose esters. HENRY DREYFUS. Fr. 642,329, Sept. 16, 1927. Cellulose substances are rendered more easily esterified, particularly acetylated, by a preliminary treatment with HCOOH, preferably of 70-90%. The cellulose may be treated with AcOH without sepn. of the HCOOH. Cf. C. A. 23, 980.

Cellulose esters. I. G. FARBENIND. A.-G. Brit. 292,929, June 25, 1927. The process described in Brit. 284,298 (C. A. 22, 4815) for varying the soly. of cellulose esters of higher aliphatic acids such as cellulose distearate or dilaurate is modified by use of an acid halide such as P oxychloride or lauryl chloride as a solubilizing reagent.

Cellulose esters. FABRIEK VAN CHEMISCHE PRODUCTEN. Fr. 642,706, Mar. 24, 1927. Stable cellulose formates are prepd. by partially formylating cellulose with a mixt. of concd. H.COOH and ZnCl₂, after which the H.COOH is sepd. and complete formylation is carried out by a mixt. of concd. H.COOH, HCl and ZnCl₂ at a temp. below 0°. The preliminary formylation may be repeated and other salts having a similar reaction may be used. The final formylation may be carried out with other active catalysts such as HCl alone or by SO₂Cl₂, POCl₃ mixed or not with salts such as ZnCl₂ or CaCl₂. Instead of completing the formylation, other esters such as the acetate, propionate, etc., may be made.

Cellulose ester. ERNESTO ORIOLI (to the Ruth-Aldo Co., Inc.). Can. 286,539, Jan. 15, 1929. Sulfuric esters of cellulose contg. up to 3% of combined sulfuric acid are treated with a mixt. of fatty acid anhydride and fatty acid; e. g., 100 g. of sulfuric ester is pressed after neutralization by washing with benzene or other suitable solvent of acetic acid, so as to represent 200 g. of moist substance and is introduced into 240 cc. of Ac₂O and 200 cc. of AcOH. The temp. rises and after 20 to 25 min. a limpid soln. is obtained. The triacetate formed may be pptd. or be subjected in soln. to further treatment.

Cellulose sulfate. ERNESTO ORIOLI (to the Ruth-Aldo Co., Inc.). Can. 286,538, Jan. 15, 1929. Approx. 100 g. of cellulose contg. 2% moisture is treated with a mixt. of approx. 4 g. H₂SO₄, 30 g. Ac₂O and 300-500 g. glacial AcOH, and after several hrs. the product is squeezed and washed with a neutral org. solvent, and then dried *in vacuo* at low temp.

Cellulose acetate. CHRISTIAN EBERT and THEODOR BECKER (to I. G. Farbenind. A.-G.). U. S. 1,701,229, Feb. 5. Cellulosic material such as cotton is treated with an acid anhydride such as Ac₂O in the presence of thionyl chloride or other suitable halogenide of sulfurous acid and a heavy metal salt such as ZnCl₂ or Cu₂Cl₂ and hydrolyzation is effected to obtain a cellulose acetate sol. in acetone or EtOAc.

Cellulose acetates. NAAMLOOZE VENNOOTSCHAP NEDERLANDSCHE KUNSTZIJDE-FABRIEK. Brit. 292,398, July 20, 1927; Fr. 642,909, Oct. 22, 1927. "After-hydrolysis" of cellulose triacetate is effected by use of a H₂SO₄ at 20° and the hydrolysis is prolonged to a point at which the viscosity of the product is 1.5 times that of the original materia

Sausage casing made of regenerated cellulose. SOC. ANON. LA CELLOPHANI. Brit. 292,582, June 24, 1927. A sheet of regenerated cellulose is formed into a tub by autogenous welding along 2 overlapping edges which may be effected by treatin the edges with a solvent such as concd. ZnCl₂ soln. and pressing the edges together.

Pyroxylin compositions. ROBERT H. VAN SCHAAK, JR. (to Van Schaack Bro

Chemical Works). U. S. 1,702,181, Feb. 12. Compns. which are used as *lacquers*, etc., comprise pyroxylin together with dibutyl phthalate, methyl-isobutyl carbinol and the acetate of methyl-isobutyl carbinol.

Esters of hexyl alcohol. HOYLAND E. YOUNG (to Van Schaack Bros. Chemical Works). U. S. 1,702,188, Feb. 12. Esters of aromatic acids such as *o*-phthalic acid, terephthalic, benzoic, salicylic or phenylacetic acid with methyl-isobutyl carbinol are made by the usual esterification methods. They are suitable for use in pyroxylin compns.

Hexyl esters. ROBERT H. VAN SCHAACK, JR. (to Van Schaack Bros. Chemical Works). U. S. 1,702,180, Feb. 12. Methylisobutylmethyl esters of propionic, oxalic, citric, valeric, palmitic, stearic, oleic, tartaric, lauric, succinic or other aliphatic acids b. above 130° are formed by various described methods. They are suitable for use in *pyroxylin lacquers*.

Mat effects on "viscose silk." B. BORZYKOWSKI (to Borvisk Syndicate, Ltd.) Brit. 292,627, June 24, 1927. The process described in Brit. 273,647 (C. A. 22, 2056) is modified by using as an addn. to the viscose org. substances contg. N such as casein or albumin, or inorg compds. such as Ba(OH)₂. The product has a luster resembling that of natural silk.

Treatment of artificial silk. DEUTSCHE ZELLSTOFF-TEXTILWERKE G. M. B. H. Fr. 642,798, July 5, 1927. Artificial silk made on centrifugal machines is submitted to all the necessary baths for its final treatment as a mass or mounted on bobbins or perforated supports in the manner described in Fr. 636,264 or 636,265.

Artificial silk from cellulose acetate. NAAMLooZE VENNOOTSCHAP NEDERLANDSCHE KUNSTZIJDEFABRIEK. Brit. 291,067, May 23, 1927. Cellulose acetate "silk" of reduced luster is obtained by introducing water vapor, as such, into the spinning cell or treating the threads formed with water vapor in a second cell. Cf. C. A. 23, 982.

Device for use in spinning artificial silk. E. WAGNER. Brit. 292,216, March 11, 1927.

Apparatus for dry-spinning of artificial silk. M. KLEIN (to Ruth-Aldo Co.). Brit. 292,561, June 22, 1927. Brit. 292,608 also relates to a modified construction of similar app.

Acidproof reel for winding artificial silk in hanks, etc. HANS C. STUHLMANN. U. S. 1,701,131, Feb. 5. Structural features.

Spinning boxes for artificial silk manufacture, etc. BRITISH THOMSON-HOUSTON CO., LTD., A. P. YOUNG, H. W. H. WARREN and R. J. CHAPMAN. Brit. 293,060, Jan. 2, 1927. Spinning boxes are made of woven fabric impregnated with insulating material such as a synthetic resin (suitably that produced from cresol and CH₂O). Various details of manuf. are described.

Ammonia recovery from dilute solutions obtained in artificial filament manufacture. HUGO HOFMANN (to American Bemberg Corp.). U. S. 1,701,265, Feb. 5. The liquor emanating from the manufacture of filaments by the cuprammonia process is treated with a Mg compd. such as MgCl₂ or MgSO₄ and with a phosphate, e. g., Na₂HPO₄, in order to effect pptn. of the NH₃.

Ammonia recovery from waste waters resulting from artificial filament manufacture by the "cuprammonia process." HUGO HOFMANN (to American Bemberg Corp.). U. S. 1,701,110, Feb. 5. The waste waters are treated with a Mg salt such as MgCl₂ and with Na phosphate, the ppt. is pressed to enrich its ammonia content, and the ammonia is sepd. from the Mg phosphate.

Sulfite liquor. MAX G. T. SCHROEDER. Can. 286,048, Jan. 1, 1929. Sulfite liquor and pure CO₂ are produced by extg. a gas contg. SO₂ with water under pressure for the recovery of SO₂ from said gas, acting with the SO₂ soln. thus obtained on a decomposable carbonate, collecting the CO₂ gas and washing the same to remove the SO₂ still admixed therewith.

Causticizing waste liquor from pulping process. JOHN S. BATES, HARRIS S. CHALMERS and PERCIVAL C. AUSTIN. Can. 286,169, Jan. 1, 1929. Alkali metal carbonate green liquor of kraft or soda pulp processes is treated in successive portions first with the sludge remaining from treatment of a previous portion and contg. Ca(OH)₂ in amt. less than the mol. equiv. of the Na₂CO₃ present in the portion with substantially complete conversion of the Ca(OH)₂, and then is treated with fresh Ca(OH)₂ in amt. substantially mol. equiv. to the original Na₂CO₃ content of the liquor. The sludge resulting from the second treatment and contg. unconverted calcium hydroxide serves for the preliminary treatment of the succeeding portion; thus the excess of Ca(OH)₂ used in treatment of the first portion is in effect transferred to successive

portions and represents the total excess of lime used in treatment of an indefinite amt. of liquor.

Paper making. KARL W. VOLLE. Ger. 470,171, Aug. 29, 1926. A device for raising the sieves of rotary cylinders, washing drums and pressure wheels in machines for paper and pulp manuf. is described.

Paper making. GEORGE A. RICHTER (to The Brown Co.). Can. 286,458, Jan. 15, 1929. A substantially uniform mixt. of mercerized cellulose fiber and beaten unmercerized cellulose fiber is run off on a paper machine and the paper nitrated.

Cellulose composition for esterification. GEORGE A. RICHTER (to The Brown Co.). Can. 286,459, Jan. 15, 1929. Mercerized cellulose fiber is run out on a paper machine into thin sheets. The paper so formed is loose and bulky, but these characteristics may be made less pronounced by incorporating a small proportion of unmercerized fiber, either beaten or unbeaten. The paper is then satd. with a cellulose xanthate soln. of sufficient cellulose concn. to yield 1-5% regenerated cellulose, when regenerated in the paper. The paper is then partially dried and immersed in a cellulose-regenerating reagent, *e. g.*, a soln. of NaHSO_4 and H_2SO_4 to regenerate the cellulose *in situ* in the paper. The paper is washed, steeped, if desired, in a sulfur-removing reagent, *e. g.*, a Na_2S soln., again washed and finally dried. The dry paper is calendered or super-calendered to improve its suitability for nitration.

Paper-making apparatus. ALONZO ALDRICH and EARL E. BERRY (to Beloit Iron Works). U. S. 1,700,301, Jan. 29. Structural features

Paper-making apparatus. RICHARD COLLINS. U. S. 1,701,226, Feb. 5. Structural features.

Paper-making apparatus. EUGENE O'BRIEN. U. S. 1,702,129, Feb. 12.

Paper-making apparatus. PAUL PRIEM (to American Voith Contact Co.). U. S. 1,702,131, Feb. 12.

"Consistency meter" for paper-making apparatus. WILBUR L. MERRILL (to General Electric Co.). U. S. 1,701,331, Feb. 5.

Suction roll for paper-making apparatus. WILLIAM H. MILLSPAUGH. U. S. 1,700,442, Jan. 29. Structural features.

Suction roll with internal stationary suction chamber for paper making and like machines. ALOIS DANNINGER. Austrian 111,746. Aug. 15, 1928.

Treating fiber of non-coniferous origin. GEORGE A. RICHTER (to The Brown Co.). Can. 286,460, Jan. 15, 1929. Sulfite fiber of non-coniferous origin is digested in a soln. of NaOH at a temp. below 70° , and then washed free of alk. soln. The treated fiber is softer and has a higher tear resistance and is better suited for the preparation of cellulose derivatives than the untreated fiber.

Treatment of ground-wood pulp. GEORGE A. RICHTER (to The Brown Co.). Can. 286,461, Jan. 15, 1929. Ground-wood pulp is digested in a 4-10% soln. of NaOH at a temp. below 70° , and the digested pulp is then washed free of alk. soln. The process is similar to that of the preceding patent. The pulp has an original pentosan content of 10 to 14% and is treated until such content is reduced to 5-7%.

Treating paper-making fiber. GEORGE A. RICHTER (to The Brown Co.). Can. 286,462, Jan. 15, 1929. Previously liberated fiber of the character of hemp and jute is digested in a 4-10% soln. of NaOH at a temp. below 70° , and the digested fiber is then washed free of alk. soln. The original fiber has a pentosan content as high as 12% and the fiber is treated until such content is reduced to about 4 to 6%. The process is similar to that of pat. 286,460 (2nd preceding pat.).

Paper bleaching. GEORGE A. RICHTER and MILTON O. SCHUR (to The Brown Co.). Can. 286,463, Jan. 15, 1929. Wood chips are digested in a NaHSO_3 liquor having a combined and a free SO_2 content of about 4% each. The pulp is then treated at a stock density of 10% with Cl water contg. about 1.5-4% Cl based on dry fiber wt. The treatment is at room temp. and for about $1\frac{1}{2}$ hr. The pulp is washed and bleached at a stock density of about 10% in a soln. contg. 5-10% NaClO or $\text{Ca}(\text{ClO})_2$ and about 0.5-2% NaOH based on dry fiber. The treatment is at room temp. or a temp. of 100° to 110° F. until the fiber is brought to substantial ultimate whiteness. The treatment does not injure the paper-making characteristics.

Beater and associated apparatus for treating paper pulp. LLOYD T. MURPHY. U. S. 1,702,230, Feb. 12. Structural features.

Pulp-fiber-cleansing apparatus. MATHIAS DEZURIK. U. S. 1,700,925, Feb. 5.

Bleaching paper pulp. JOHANNES RUTHS (to Ruths Accumulator Aktiebolag). U. S. 1,700,647, Jan. 29. Steam generated in uniform quantity is accumulated in a storage container and substantially the entire volume of stored steam is then supplied to a bleaching hollander contg. pulp.

Pulp refining "engine" of the conical type. W. G. FRASER. Brit. 292,228, March 14, 1927. Structural features.

Apparatus for coloring, sizing or impregnating of paper webs. I. G. FARBERIND. A.-G. Brit. 293,000, June 29, 1927.

Softening paper. I. G. FARBERIND. A.-G. Brit. 292,430, March 16, 1927. Paper such as parchment paper is softened by treatment with sorbitol or its dehydration products which are obtainable from sorbitol by heating with suitable catalysts. Other substances such as glycerol, glycol, Na lactate or inorg. hygroscopic salts may also be added. The sorbitol and derivs. may be mixed with paper pulp or added to the paper at any stage of manuf.

Weighing and indicating apparatus for testing paper in sheets. EDWARD G. THOMAS (to Toledo Scale Co.). U. S. 1,701,021, Feb. 5.

Treated paper for making show cards, etc. G. S. WALPOLE. Brit. 292,804, Aug. 18, 1927. In the "cutter-crush" process the paper from which the characters are cut is treated or coated on its underside with a mixt. such as paraffin or beeswax, to which Japan wax or cacao butter may be added, and may be sized to prevent penetration of the wax.

24—EXPLOSIVES AND EXPLOSIONS

C. E. MUNROE

Explosive limits (of gases) to be observed in factories. G. WEISSENBERGER AND P. PATTI. *Z. angew. Chem.* 41, 1262-4(1928).—Safety precautions. E. M. S.

Safe transportation of explosives underground. F. J. BYRNE. *Min. Congress J.* 4, 781-4(1928). E. M. S.

How volatile solvents behave. A. G. SMITH. *Nat. Safety News* 18, 90-2(1928).—There is danger from flammable vapors. E. M. S.

The relative inflammability and explosibility of coal dusts. T. N. MASON AND R. V. WHEELER. *Safety in Mines Res. Board* (London) Paper No. 48, 3-13(1928).—This paper is supplementary to S. M. R. B. Paper No. 33 (*C. A.* 21, 2190). Expts. are described here in which explosions were produced with a no. of different coal dust under standard conditions with a view to det. their relative "inflammability" as measured by the mean speeds of the flames over a given distance, and their relative "explosibility" as measured by the max. pressure developed and the data show that the order of inflammability and that of explosibility as thus detd. are approx. the same. These orders are also in close agreement with the order of inflammability as detd. for the same coals from the proportions of incombustible dust required to suppress inflammation. In Paper 33 a relationship was shown to exist between the inflammability of the dust and its content of volatile matter. The present work confirms the value of the volatile matter detn. as a guide to the degree of inflammability of a coal dust.

The behavior of nitrocellulose gels in polarized light (PHILLIPS) 2. The chemical industry in Sweden. (ANON) 13. Negative catalysts and β -naphthol as a medium for preventing spontaneous combustion of oily textile fibers (POMERANZ) 27. How to avoid fire in storing Indiana screenings (TUTTLE) 21.

Device for quenching flame from blasting charges by use of water. M. WITTE. Brit. 292,802, Aug. 11, 1927.

Waterproofing paper shot cartridges. STANLEY L. WILLIS and WATSON H. WOODFORD (to Remington Arms Co.). U. S. 1,701,868, Feb. 12. The top wad and crimp are sealed and impregnated with a compn. contg. a polymerizable oil such as Chinese wood oil and a drier comprising Mn resinate and Pb oxide.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

World's dyestuff industry. L. J. HOOLEY. *Ind. Chemist* 5, 6-8(1929). E. H. Interesting sources of natural dyestuffs. C. D. MELL. *Textile Colorist* 51, 111-4 (1929).—"Mucic Blue" from the plant *Jacobiana spicigera* is used in parts of Mexico for whitening clothes. The entada or giant-bean (*Entada scandens*), an interesting

plant because of its peculiar growth and varied uses, may be a source of red dye. The natives of South Africa use a small bush known locally as "Eland's boontjes" (according to Bentham, the *Elephantorrhiza burchelli*) for food, medicine, tan and dye. White woods and moleskins are dyed a mahogany hue by it. The amount of tannic acid is said to vary between 13 and 20%. In West Africa, the fruit pods of the tamarind tree (*Tamarindus indica*) are used by the natives as an aid in coloring skins (particularly goat skins) leather and fabric. The use of tamarind pulp appears to be an important factor in the process of dyeing yellow with certain coloring substances. R. K. W.

French dyestuffs. The rise of an industry. DONAT AGACHE. *Times Trade and Eng. Supplement* (London) 23, 49(1928). E. M. SYMMES

Chemistry of the dye bath. Theories of yesterday and today. P. E. KING. *Times Trade and Eng. Supplement* (London) 23, 44(1928).—Wool, silk and cotton are negatively charged when placed in water, as are also certain classes of dyestuffs. Wool in an acid liquor is positively charged, as are basic dyestuffs. The modern tendency is to regard dyeing phenomena as resulting from more than one factor, e. g., chem. adsorption and elec. actions may occur. E. M. SYMMES

Modern theories of dyeing. A. JACKSON. *Dyer, Calico Printer* 58, 248-9(1927); 59, 18-19, 30-1, 52 3(1928).—The mech., chem., soln., absorption, colloidal and elec. theories are discussed; the conclusion favors the elec. theory. C. E. M.

Lactic acid in dyeing. FRED. GROVE-PALMER. *Dyer, Calico Printer* 59, 37, 53 (1928). CHAS. E. MULLIN

Lactic and formic acids in the dyehouse. FRED. GROVE-PALMER. *Dyer, Calico Printer* 59, 122-3(1928). CHAS. E. MULLIN

Mechanism of the stabilizing of Naphthol AS solutions with formaldehyde. KURT BRASS. *Leipzig. Monatschr. Textil.-Ind.* 43, 213-5(1928).—The addn. of HCHO to the alk. soln. of Naphthol AS gives a quant. yield of $(C_{10}H_7(ONa)CONHC_6H_4)_2CH_2$, the reaction following the same course as that between β -naphthol and HCHO. Presumably a similar methylene deriv. is obtained from each of the comm. Naphthol AS products. These products when isolated are found to be more stable than the β hydroxy naphthoic acid arylides otherwise present. In fact, a prepn. of the compd. above represented showed only a trace of cloudiness on standing 48 hrs. while Naphthol AS similarly dissolved gave a dense gray ppt. in the same time. The mono-Na salt, of the Naphthol AS-HCHO reaction product show inferior stability. F. R. CLARK

Fastness of dyed shades. H. MALDWIN WILLIAMS. *Wool Record* 34, 1733-5, 1743(1928).—Methods are briefly described for testing the fastness of dyed fabrics to light, scouring, milling, stoving, potting and steaming, perspiration, carbonizing, rubbing or cracking, street mud, and hot pressing and soaping. R. K. W.

The affinity of wool for dyestuffs. F. T. SYKES. *Dyer, Calico Printer* 59, 94-6 (1928).—The various methods of affecting the affinity of wool for dyestuffs are discussed. CHAS. E. MULLIN

Fastness to light of tints on woolens. J. MOFFAT. *Dyer, Calico Printer* 59, 78-9 (1928).—Dyestuffs suitable for tints on wool are suggested. CHAS. E. MULLIN

Testing the suitability of dyes for viscose silk: a new rapid test. A. J. HALL. *Textile Recorder* 46, No. 548, 85(1928).—See C. A. 22, 4252. RUBY K. WORTNER

Process for correction of viscose unevenly dyed with direct cotton dyestuffs. COURTAULDS, LTD. *Wool Record* 34, 1325-7(1928).—Viscose, thus dyed, may be considerably improved in the majority of cases by working it for 30 min. at 90° in a bath contg. 1 lb. β -naphthol and 1 lb. NaCl per 10 gal. water. Also in *Rayon* 7, No. 12, 18-9(1928). RUBY K. WORTNER

Clearing alizarin reds and aniline black prints—oxidation discharges. WILHELM SIEBER. *Silk J.* 5, No. 51, 61-2(1928).—For clearing alizarin red prints it is suggested to use the clear soln. from 25 l. of 6.5° Tw. $Ca(OC_2H_5)_2$ soln., 2.5 kg. $Na_2I_2O_4$ and 57.5 l. H_2O . This is padded on to one side of the cloth only, and the cloth is then led over the hot drying cylinders as quickly as possible. Aniline black prints are cleared by padding with a 0.1 to 0.5% $KMnO_4$ soln., squeezing and passing full width through a dil. bisulfite soln. The goods are again squeezed and washed, allowed to lie for some time, treated in rope form with very dil. H_2SO_4 or HCl, washed, soaped and washed. Formulas are also given for oxidation discharges on direct colors. CHAS. E. MULLIN

Humidity a greater factor than ever in textile manufacturing. R. H. BROWN. Parks-Cramer Co., Fitchburg, Mass. and Charlotte, N. C. *Textile World* 75, 763-4 (1929). RUBY K. WORTNER

The sizing of warps. J. W. HUTCHINSON. *Wool Record* 34, 1537-9, 1673-5 (1928); 35, 241-3(1929).—The sizing of woolen, worsted, cotton and rayon warps is described and discussed. RUBY K. WORTNER

Sizing of artificial silk. JAMES SCOTT. *Silk J.* 5, No. 51, 65-7(1928).—Very general. CHAS. E. MULLIN

Advance of artificial-silk industry. J. E. FEATHERSTONE. *Dyer, Calico Printer* 59, 84-5(1928).—Recent developments in manuf., uses and production of rayon are briefly discussed. CHAS. E. MULLIN

Immunized and amidated cotton. S. R. TROTMAN. *Dyer, Calico Printer* 59, 92 3, 117(1928).—The properties of immunized and amidated cotton are discussed. CHAS. E. MULLIN

Progress in finishing cotton piece goods during the year. WINN W. CHASE. *Textile World* 75, 927-9(1929). RUBY K. WORNER

Continental wool textile industry. The coördination of research work. ARNOLD FROBISHER AND J. A. F. ROBERTS. *Wool Record* 33, 1627, 1633(1928).—A tour of scientific institutions carrying on wool research in Germany, France and Belgium is described. RUBY K. WORNER

The bleaching of wool piece goods. J. SCHOFIELD AND J. C. SCHOFIELD. *Wool Record* 34, 373 5, 441 3, 509-11, 515, 577 9(1928).—A general account is given of the bleaching of animal fibers by the use of sulfur compounds, peroxides or perborates, permanganates followed by sulfurous acid, etc., and tinting processes. R. K. W.

The chlorination of wool goods. J. SCHOFIELD AND J. C. SCHOFIELD. *Wool Record* 34, 1121 3, 1189 91, 1199(1928).—The methods used in practice for obtaining active Cl and the effects of chlorination on wool fabrics are considered. RUBY K. WORNER

Scouring of worsted fabrics. L. L. LLOYD. *Wool Record* 34, 1257-9(1928).—Practical. RUBY K. WORNER

Solvent scouring and cleaning. VERNON D. FREEDLAND. *Dyer, Calico Printer* 59, 76 7, 118 9(1928). The common solvents used in prepg. the solvent soaps are discussed. *Chlorethol* is a mixt. of tetrachloroethane, alc. and sol. oil; *gartol* is a mixt. of trichloroethane, heavy paraffin oil, soft soap and sol. oil; *tetrapol* is a mixt. of CCl_4 and sol. oil. *Westrol* and *Westropol* are similar mixts. of halogenated hydrocarbons and soap. The *solvent scouring of wool* is also described. CHAS. E. MULLIN

The art of waterproofing. CLIFFORD R. CARTER. *Indian Textile J.* 39, 41-2 1928. Formulas are given for waterproofing tarpaulins, linens, canvas, cart covers and similar materials. The making of "oilskins" is also described. R. K. W.

Nomography is not only easier and quicker—it is more accurate. EDWARD R. SCHWARZ. Mass. Inst. of Technology. *Textile World* 75, 765 8(1929).—A review is given of some recent attempts to simplify textile calcs. RUBY K. WORNER

Sodium silicate. H. O. RICHARDSON. *Dyer, Calico Printer* 59, 150(1928).—The applications of Na silicate in the textile industry are discussed. CHAS. E. MULLIN

Rayon oils. CHAS. E. MULLIN. Textile School of Clemson Coll. *Textile Colorist* 50, 265 8, *Melliand Textilber.* (Ger.) 12, 995 7(1928); *Melliand Textilber.* (Eng.) 10, 29 31(1929). It is common practice to oil rayon (1) at the factory, usually during the last rinse; (2) after dyeing, when dyed in the skein; and (3) before winding on to cones for knitting or on cops for weaving. Different types of oil are generally used for each process but all of these oils should be readily removable from the fiber in the usual soap scour without the addn. of alkalis. Alkali should never be used upon rayon or on goods contg. it if the best results are desired. The chem. and hygroscopic properties of viscose and the other regenerated-cellulose rayons are discussed and compared with those of cotton and mercerized cotton. In order to obtain uniform shades, care must be exercised in scouring and bleaching rayons, and p_H control is suggested. *p_H control of the scouring bath* may also be an aid in obtaining more uniform rayon during the mfg. process. Rayon is oiled in order to (4) soften and (5) lubricate the fiber during the process of winding, knitting, etc.; (6) to reduce the amt. of moisture absorbed from the air, and (7) to give the fibers a certain cohesiveness, which is desirable to avoid the difficulties caused by its natural wiriness in winding it off of the cop or cone. The oiling for winding is often conducted by (8) soaking the skeins in pans of oil and hydroctg. or draining; (9) spraying with the desired percentage of oil and draining; (10) or merely pouring the desired percentage of oil into the opened rayon package and allowing it to permeate through the fibers by capillarity. Mineral oils are excellent for rayon in every way except as regards to their removal by scouring. Therefore, they should seldom be used alone. Blended oils are suggested and some of the oils now in use are discussed. The pin-holes sometimes occurring in viscose goods that have been oiled with animal or vegetable oils are discussed. They are supposed to be due to traces of S remaining in the viscose silk from the mfg. process acting upon the oil. CHAS. E. MULLIN

Stains produced by machine lubrication. L. L. LLOYD. *Wool Record* 34, 1393-5

(1928).—In looms, in consequence of frictional abrasion, the lubricant becomes intermingled with finely divided Fe, which catalyzes the oxidation of the oil. This oil, as well as the iron compounds formed from the fatty acids of the oil, is more difficult to remove either by solvents or by emulsification than is the unaffected oil. Stains from the combination of graphite and oil are even more difficult to remove. The stains are best removed as soon as the material is taken from the loom. Efficient solvents or cleansing agents are available, which can be used without any appreciable damage to the fiber.

The deburring of skins: an Australian invention. ALFRED F. BARKER. *Textile Recorder* 46, No. 546, 51-2(1928).—An illustrated description is given of the Vicar's machine, which removes the vegetable matter by a combing action before the wool is taken from the skin. The method is considered particularly promising.

RUBY K. WORNER

Total-fat determination in sulfonated oils for use in the textile industry (HERBIG) 27. American coal-tar industry. Growth of dyestuffs production (TALBOT) 21. Dyes. I. GUBELMANN and J. B. OESCH (to Newport Co.). Brit. 292,904, June 25, 1927. 4,4'-Dimethyl-6,6'-dichlorothioindigo is treated in concd. H_2SO_4 soln with a brominating agent such as free Br until up to 2 atoms of Br are introduced. The dye contg. 1 atom of Br dyes cotton red from a yellow vat. By varying the concn of acid, dyes giving different shades of red are produced.

Dyes. SOCIÉTÉ ANON. POUR L'INDUSTRIE CHIMIQUE À BÂLE. Brit. 292,622, June 24, 1927. Mixts. of symmetrical 1,2- and 2,1-naphththioindigos are used for dyeing and printing to obtain greater brightness and fullness than when the dyes are used separately. Numerous examples and details are given.

Dyes. I. G. FARBENIND. A.-G. Brit. 292,741, May 5, 1927. Violet vat dyes are made by condensing a halogenated perylenetetracarboxylic acid contg. not more than 3 halogen atoms in the mol. with an *o*-diamine such as *o*-phenylenediamine. The products give dyeings on cotton from the vat fast to soaping, light, Cl and to boiling Na_2CO_3 soln.

Dyes. I. G. FARBENIND. A.-G. Brit. 292,344, June 9, 1927. Cr compds. of *o*-hydroxyazo dyes yielding on wool reddish violet to bluish violet dyeings fast to washing, milling and light, are made by the action of tervalent Cr compds on dyes produced by coupling diazotized 4-chloro-2-aminophenol with a naphtholmonosulfonic acid.

Dye. I. G. FARBENIND. A.-G. Fr. 643,414, Nov. 7, 1927. A new vat dye is prepd. by reaction on the diazo compd. of the aminobenzanthrone obtained by reduction of the nitrobenzanthrone described in example 2 of Fr. 6435/349,531 (by boiling benzanthrone with AcOH under reflux and adding 47° Bé. HNO_3 in AcOH and continuing to heat) with a sulfurized sol. compd. and treatment of the product of reaction with alk. agents. In an example the aminobenzanthrone referred to is diazotized and a suspension thereof in water is poured slowly into a soln. of K xanthate in water, and the mixt. is heated to 85°. The product, with or without removal of resinous matter, is heated to 280° rapidly with KOH-EtOH, and poured into water. The product dyes cotton blue from the vat turning to a strong black in air.

Dyes. I. G. FARBENIND. A.-G. Fr. 643,388, Nov. 5, 1927. New vat dyes are obtained by treating *N*-alkylated benzanthranyl-1-aminoanthraquinones with alkalis. The *N*-methyl deriv. of Bz-1-benzanthranyl-1-aminoanthraquinone is agitated with EtOH-KOH at about 98°. The product is poured into water and the dye is pptd. by bubbling air through. It dyes cotton violet from the vat, which turns to a green-blue much purer than that obtained in example 1 of Fr. 396,583.

Dyes. I. G. FARBENIND. A.-G. Fr. 643,386, Nov. 5, 1927. New orange vat dyes are obtained by introducing polyatomic alc. radicals into the OH groups of 1-benzoylamino-4-hydroxyanthraquinone. Examples, 1-benzoylamino-4-hydroxyanthraquinone is boiled with the chloroethyl ester of *p*-toluenesulfonic acid. The dye obtained

may be divided into 2 components by crystn. from PhNO_2 . The more sol. contains compds. in which the H of the OH group is replaced by $-\text{CH}_2\text{CH}_2\text{Cl}$ and $-\text{CH}_2-\text{CH}_2\text{OH}$. The less sol. portion contains a product of the formula $\text{XCH}_2\text{CH}_2\text{X}$, where X represents the mol. of the starting material less the H atom of the OH group. This less sol. product is also obtained if the di-*p*-toluenesulfonic ester of ethylene glycol is used. The 1-benzoylamino group may be replaced by a 1-*m*-methoxybenzoylamino group to obtain a product which dyes vegetable fiber in strong yellowish orange shades. The tri-*p*-toluenesulfonic ester of glycerol also may be used.

Dyes. I. G. FARBENIND. A.-G. (Georg Wolfsleben, inventor). Ger. 469,946, Sept. 7, 1926. A black tetrakisazo dye, particularly for *chrome leather*, is prepd. by allowing 2 mols. of the diazo compd. of *p*-aminoacetanilide to act upon 1 mol. of the disazo dyestuff obtainable from 1 mol. of the tetrazo compd. of benzidine, by acid coupling with 1 mol. of H-acid, followed by alk. coupling with 1 mol. of *m*-phenylenediamine, the resulting tetrakisazo dye being afterwards sapond. in an alk. medium. An example of the prepn. is given.

Dyes. L. B. HOLLIDAY & Co., LTD., J. KITSON and C. SHAW. Brit. 293,110, March 30, 1927. Chloranil or bromanil is heated with aq. alkali and thus by hydrolysis yields the insol. alkali 2,5-dihydroxy-3,6-dichlorobenzoquinone or alkali 2,5-dihydroxy-3,6-dibromobenzoquinone and a dye which dyes wool and silk brown tints which may be pptd. with acid or by salting out. Other similar processes also are described.

Azo dyes. I. G. FARBENIND. A.-G. (Hermann Wagner, inventor). Ger. 470,178, Feb. 25, 1922. Diazo compds. are combined with *o*-aryloxy- or *o*-aralkyloxyarylides of 2,3-hydroxynaphthoic acid. Thus, chloroanisidine is diazotized and combined with 2,3-hydroxynaphthoic acid 5-chloro-2-phenoxy-1-anilide. Other examples are given.

Yellow monoazo dyes. HERMANN WAGNER and BARTHOLOMAUS VOSSEN (to Grasselli Dyestuff Corp.). U. S. 1,701,248, Feb. 5. Yellow monoazo dyes of good fastness to light are made by diazotizing 2,5,6-trichloro-3-amino-1-methylbenzene-4-sulfonic acid and coupling it with compds. such as 1-sulfophenyl-3-methyl-5-pyrazolone, 1-sulfophenyl-5-pyrazolone-3-carboxylic acid, 1-sulfophenyl-5-pyrazolone-3-carboxylic acid ester or 1-(3-sulfo-6-chloro)-phenyl-3-methyl-5-pyrazolone. The 2,5,6-trichloro-3-amino-1-methylbenzene-4-sulfonic acid can be made by chlorinating *p*-toluenesulfonic acid, *p*-chlorotoluene-*p*-sulfonic acid or 2,6-dichlorotoluene-4-sulfonic acid until these compds. have attained the wt. of a trichloro compd. and then nitrating and reducing.

Green trisazo dyes for cotton. HEINRICH CLINGESTEIN (to Grasselli Dyestuff Corp.). U. S. 1,701,717, Feb. 12. A diazotized aminoazo compd., such as aminoazotoluene-sulfonic acid obtainable from *p*-sulfanilic acid and *o*-toluidines is coupled with a 1-amino-2-naphthol ether or a deriv. such as the Et ether of 1-amino-2-naphthol-6-sulfonic acid, and the intermediate thus formed is diazotized and coupled in an alk. medium such as a soda soln. (with or without the use of pyridine, which, if present, accelerates the coupling) with a 1-acylamino-8-hydroxynaphthalenesulfonic acid. The dyes thus prepd. form alkali metal salts which are generally dark powders, sol. in water, and dye cotton various green shades of good fastness to light. Several examples are given.

Dyes and intermediates. I. G. FARBENIND. A.-G. Fr. 642,906, Oct. 22, 1927. 3,5-Dihal-2-amino-1-toluene is diazotized and converted into the 2-nitrile compd., which is sapond. by means of 65% H_2SO_4 at boiling temp., into the corresponding carboxylic acid. An example is given of the prepn. of 3,5-dichloro-1-toluene-2-carboxylic acid which may be converted by the method of Ger. 189,200 or otherwise into the corresponding oxythionaphthene and thence into a thioindigo dye.

Intermediates for dyes. THE NEWPORT Co. Fr. 642,931, Oct. 24, 1927. 1-Amino-2,4-dichloroanthraquinone is prepd. by condensing *m*-dichlorobenzene with phthalic anhydride to form 2',4'-dichloro-*o*-benzoylbenzoic acid, nitrating to obtain 3'-nitro-4',6'-dichloro-*o*-benzoylbenzoic acid, reducing the latter to the amino compd. and dehydrating with concd. H_2SO_4 at a temp. of 150-160° to close the ring.

Intermediates for dyes. I. G. FARBENIND. A.-G. Fr. 642,810, Aug. 18, 1927. New benzyl compds. are obtained by the reaction at ordinary temp. of a halogenated Me deriv. of a hydroxy aromatic compd. with an aromatic amine or deriv. thereof. In examples, to 2,5- $\text{HO}(\text{ClCH}_2)_2\text{C}_6\text{H}_3\text{CO}_2\text{H}$ a soln. of *m*-sulfanilic acid in Na_2CO_3 soln. is added. The soln. is acidified after 24 hrs., and $\text{HO}_2\text{SC}_6\text{H}_4\text{NHCH}_2\text{C}_6\text{H}_4(\text{OH})\text{CO}_2\text{H}$, a white powder, is pptd.; and similarly, chloromethylcresotic acid and 2,8-amino-naphthol-6-sulfonic acid give a yellow crystalline powder, 2,4- $\text{HO}(\text{HO}_2\text{S})\text{C}_6\text{H}_3\text{NH}-\text{CH}_2\text{C}_6\text{H}_4\text{Me}(\text{OH})\text{CO}_2\text{H}$, 3,4,5. Compds. are obtained with *m*-NHMe and pyridine.

Copper compounds of dyes. I. G. FARBENIND. A.-G. Brit. 292,660, March 18, 1927. See Fr. 632,941 (C. A. 22, 3535).

Isatin derivatives. MAXIMILIAN P. SCHMIDT and OTTO HERRMANN (to Grasselli Dyestuff Corp.). U. S. 1,700,814, Feb. 5. Isatin derivs. which are sol. in water and which can be combined in aq. soln. with a reactive ketomethylene compd. such as naphthol, oxythionaphthene, indoxyl or acenaphthenone to produce *indigoid dyes* are prepd. by the action of sulfites upon isatin- α -chlorides, their substitution products, homologs or analogs. Preferably the isatin- α -chloride is suspended in an aq. soln. of Na_2SO_3 (suitably of 10% strength) and slowly heated to about 90° with stirring; the chloride gradually dissolves and the reaction product may be sepd. from the soln. by salting out as with NaCl . The new isatin derivs. can also be obtained from the dehydroindigo bisulfites described by Kalb (C. A. 4, 201). They differ from the previously known bisulfite addition products by their intense yellow color and by their fastness to dil. acids. When spread in soln. on a support such as paper and exposed to light they are decomposed. Examples and details of procedure are given.

1-Acetylanthraquinone. I. G. FARBENIND. A.-G. Swiss 127,253, May 24, 1927. 1-Acetylanthraquinone is prepd. by oxidizing *Bz*-1-methylbenzanthrone with CrO_3 in AcOH soln. The product is useful as an intermediate for dyes. Cf. Brit. 289,585 (C. A. 23, 715).

Diazo compound of 2-amino-5-chlorophenol. COMPAGNIE NATIONALE DE MATIÈRES COLORANTES ET MANUFACTURES DE PRODUITS CHIMIQUES DU NORD RÉUNIES (Établissement Kuhlmann). Fr. 643,560, Apr. 12, 1927. When alkalis such as Na_2CO_3 or salts of org. acids such as NaOAc are caused to react on the diazo compd. of 2-nitro-4-chloroaniline, the nitro group is replaced by a OH group, giving the new diazo compd. of 2-amino-5-chlorophenol. The latter reacts in the presence of Na_2CO_3 with a large no. of known coupling components, such as naphthols, and their sulfo and amino derivs., dihydroxynaphthalenes and their derivs., resorcinol, and pyrazolones, giving dyes which dye wool in an acid bath, the colors being improved by an after-treatment with $\text{K}_2\text{Cr}_2\text{O}_7$ and H_2SO_4 . The dyes give with metal salts new compds. which dye wool directly in fast shades. Several examples and tables of dyes are given.

Nitro-2,3-dichloro-1,4-naphthoquinone. I. G. FARBENIND. A.-G. Fr. 643,117, Nov. 7, 1927. A mixt. of HNO_3 and H_2SO_4 is heated with 2,3-dichloro-1,4-naphthoquinone to 40 – 50° . The crude product on crystn from AcOH or alc. crystallizes in 2 forms, either as clear yellow needles or yellow scales. Both forms are chem. identical have the same m. p., 175° , and the formula is probably 2,3-dichloro-8-nitro 1,4-naphthoquinone, which is an *intermediate for vat dyes*.

1-Diazoanthraquinone-2-carboxylic acids. LUDWIG EIFFLENDER (to Grasselli Dyestuff Corp.). U. S. 1,700,790, Feb. 5. 1-Diazoanthraquinone-2-carboxylic acids are obtained by the action, in the presence of water, of HNO_2 or substances liberating it, on the nitrogenous anthraquinone derivs. obtainable from 1-nitro-2-methylantraquinone or its substitution products as described in U. S. pat. 1,417,875 (C. A. 16, 2696), these derivs. being generally regarded as anthraquinone-isoxazoles. The diazo compds. thus obtained may be used for the production of other anthraquinone-2-carboxylic acids, otherwise substituted in the 1-position, such as 1-chloroanthraquinone-2-carboxylic acid or its 5-nitro or other derivs. and also may be used for the production of *azo dyes*. Examples are given.

Sulfonated aliphatic acids. I. G. FARBENIND. A.-G. Fr. 636,817, June 29, 1927. Higher unsatd. acids are sulfonated along with phenols by means of oleum. The products are used in the textile and dyeing industry in place of Turkey red oils. Cf. C. A. 23, 536.

Phosphomolybdotungsten compounds; lakes. I. G. FARBENIND. A.-G. Brit. 292,253, March 17, 1927. Phosphomolybdotungsten compds. prepd. as described in Brit. 216,486 (C. A. 19, 183) are reduced by reducing agents such as SO_2 , bisulfites, hyposulfites or grape-sugar to produce black cryst. compds. the salts of which differ from each other in soly. similarly to the unreduced substances. The reduction products are capable of reconversion into the parent substances by use of oxidizing agents such as permanganate or H_2O_2 and are suitable for the *production of lakes* with basic dyes or with acid dyes contg. sulfo groups and free or combined amino groups; rhodamine B gives a red lake very last to light. Cf. C. A. 22, 3996.

Dyeing. I. G. FARBENIND. A.-G. Brit. 292,658, March 18, 1927. Fast dyes are obtained on animal, vegetable or artificial fibers by use of a slightly alk. vat contg. the products resulting from melting 1-hydroxyanthraquinone or a suitable deriv. with NaOH , such as dyes made as described in Brit. 292,806 and 292,897 (following abstract).

Dyes. I. G. FARBENIND. A.-G. Brit. 292,896, March 18, 1927. Fusions as

specified in the preceding abstract are effected in the presence of an org. solvent or suspension medium, preferably with exclusion of O. The products may be purified by fractional pptn. from H_2SO_4 or (as is described in Brit. 292,897) by use of oxidizing agents such as hypochlorite and permanganate solns.

Dyeing. I. G. FARBENIND. A.-G. Brit. 292,100, June 13, 1927. Diazonium and tetrazonium borofluorides of arylamines are combined with 2,3-hydroxynaphthoic arylides, pyrazolones, dipyrazolones, acetoacetic acid arylides or diacetoacetic acid diamini-diaryl compds. on the fiber. Several examples are given of dyes producing various red shades.

Dyeing. MARCEL BADER and CHARLES SUNDER. Fr. 33,148, Mar. 14, 1927. Addn. to 551,666. Products sol. in water are obtained by treating leuco derivs. of vat dyes with NH_2SO_3H in the presence of a tertiary base such as pyridine or $PhNMe_2$. The products, which are the same as those obtained in Fr. 551,666 by using $ClSO_2H$, find various applications in dyeing and printing textiles. In examples, the leuco deriv. of tetrabromoindigo is suspended in $PhCl$ and pyridine is added. To the mixt. heated to 75–80° NH_2SO_3H is gradually added. The product is the NH_4 salt of the sulfuric acid ester of tetrabromoindigo. The leuco deriv. of thioindigo and of dimethoxydibenzanthrone are similarly treated.

Dyeing. BRITISH DYESTUFFS CORPORATION, LTD., and JAMES BADDILEY, PERCY CHORLEY and CARLTON BUTLER. Fr. 33,207, Mar. 21, 1927. Addn. to 631,115. Artificial silks from regenerated cellulose are dyed by diazo compds. prep'd. by combining diazotized aminosalicyclic acids or their homologs with the usual components, diazotizing again and combining with naphtholsulfonic acids, naphthylaminesulfonic acids or the *N* substitution products of the latter. Examples are given.

Dyeing. HENRY DREYFUS. Fr. 33,247, Mar. 16, 1927. Addn. to 568,655. Materials composed of, or contg. cellulose acetate are dyed, printed, etc., by insol. or relatively insol. dyes made sol. by means of soaps of sol. resin or Na salts or soaps of resinic acid. A suitable comp'd. is prep'd. by adding powd. pale com. resin to a boiling $NaOH$ soln., boiling for some hrs. and cooling. Examples are given of dyeing with dyes made sol. with this comp'd.

Dyeing. WOLDEMAR FEHRMANN. Ger. 469,837, Feb. 17, 1925. App. is described for dyeing and other wet treatment of fabric, in which the dye liquor, etc., is kept in motion by air pressure.

Dyeing with aniline black. KARL SCHMIDT. Fr. 643,678, Nov. 9, 1927. To prevent weakening of the fiber in dyeing textile materials with aniline black, large quantities of salt of feeble acids, volatile or easily oxidizable, or salts formed from acids and aromatic amines are added to the mixt. of agents used for the dyeing. This mixt. contains a salt of Fe, Mn, V, Pb or other heavy metal, and aromatic amines, phenols, *N* compds., diazo, halogen or nitro compds. or certain org. acids. Examples of baths are given contg. (1) $PhNH_2 \cdot HCl$ 12, $CuSO_4$ 1.2, $NaClO_4$ 5, $(NH_4)_2SO_3$ 4, and *p*-phenylenediamine 2 parts; (2) $PhNH_2 \cdot HCl$ 12, $K_4Fe(CN)_6$ 9, $NaClO_4$ 5, $(NH_4)_2SO_3$ 5, *p*-phenylenediamine 2, and tartaric acid 3 parts.

Dyeing cellulose derivatives. HENRY DREYFUS. Fr. 643,323, Nov. 3, 1927. Material made of, or contg. cellulose esters is treated with swelling agents before mordanting, whereby the mordants are more easily taken up. As swelling agents, $HCOOH$, $AcOH$, glycolic acid, lactic acid, $EtOH$, Me_2O , alcohol-diacetone, diacetin, phenol, hydroquinone, cyanates, thiocyanates; urea, urethans, thiourea, guanidine and substitution products thereof may be used.

Dyeing cellulose esters and ethers. H. DREYFUS. Brit. 292,452, Dec. 14, 1926. Cellulose derivs. such as those described in Brit. 291,118 (*C. A.* 23, 1287) are dyed, printed, stenciled or otherwise colored with coloring substances of the azo, nitro-diaxylamine, nitrodiarylmethane or anthrapyridone series contg. one or more urethan or substituted urethan residues. When azo dyes are used they may be formed or developed on the fiber. Several examples and methods of prepg. the dyes are given. Brit. 292,454 specifies the use, as coloring substances, of azo compds. (other than urea or thiourea derivs.) contg. one or more ω -groups in the diazo component. Various examples, details and modifications are described.

Dyeing cellulose esters and ethers. H. DREYFUS. Brit. 292,180, Dec. 14, 1926. Materials such as cellulose formate, acetate, propionate or butyrate, "immunized cotton" methyl, ethyl or benzyl cellulose or condensation products of cellulose with glycols or the like are dyed, printed, stenciled or otherwise colored with azo compds. contg. one or more amino groups substituted by one or more aliphatic side chains each contg. 2 or more OH groups but no COOH groups. Various solubilizing agents may be used and several examples are given, among which is the use of the product

table fibers such as flax, jute, hemp, etc., are prepd. for application as textiles and the like by boiling in a 2% NaOH soln., washing with water, then with acid to which a small quantity of NaOCl may be added, again washing and boiling in water contg. an oil such as linseed oil and an alkali.

Extracting fibers. MARCEL VALENTIN. Fr. 643,423, Nov. 7, 1927. A machine is described for extg. agave and like plant fibers in which the leaves are cut into longitudinal strips and passed to a shredder.

Apparatus for preparing fiber from hemp, flax, sisal, yucca, etc., by treatment with liquid reagents, etc. J. C. W. STANLEY. Brit. 292,801, Aug. 10, 1927.

Treating yarns. THOMAS MCCONNELL. Ger. 469,838, Sept. 19, 1925. Yarn is led to a mercerizing or other bath through rollers, over a guide and under a roller in the bath, then between stretching members which are positively rotated and comprise spiders with rollers connecting the free ends of corresponding arms, thence again into the bath and then up between similar stretching members.

Apparatus for sizing textile fibers or threads. CHARLES F. TOPHAM (to Courtaulds, Ltd.). U. S. 1,702,140, Feb. 12.

Apparatus for sizing, dressing and drying threads. V. BONNIER. Brit. 292,935, June 25, 1927.

Washing artificial silk. SPINNSTOFFWERK GLAUCHAU AKTIENGESSELLSCHAFT and HEINRICH VOSS. Fr. 642,645, Oct. 21, 1927. Artificial silk thread on perforated bobbins is washed with liquid while air, gas, or vapors are passed through. Neutralizing gases such as NH_3 may be used.

Crepe de chine from artificial silk. GEORGES COUDENE. Fr. 642,757, Mar. 29, 1927. Artificial silk threads to be used for making "crepe de chine" and the like is made of 2 or more elementary threads twisted together, the said elementary threads being previously twisted in the sense opposite to that of the twisting together.

Moire artificial silk. CAMILLE DREYFUS. Fr. 643,058, Oct. 27, 1927. Permanent moire effects are obtained on fabrics composed entirely or for the greater part of cellulose acetate, cellulose propionate, ethylcellulose or other org. deriv. of cellulose by the method used for other textiles.

Driving and conveyer belts of tussah silk. W. EBELL. Brit. 293,209, July 23, 1927. Tussah silk is stated to be more resistant to chemical action than other varieties of silk. Cf. C. A. 22, 504.

Degreasing wool. I. G. FARBENIND. A.-G. Fr. 642,385, Sept. 21, 1927. Crude wool is degreased by means of hydrocarbon chlorides, the b. p. of which is about 100–150° C., e. g., xylol chloride.

"Substitute for wool" made from jute waste. B. H. KANTAWALA. Brit. 293,161, May 16, 1927. Jute waste is treated with an emulsion of ground-nut oil and NaOH, allowed to stand until thoroughly damped and then passed through a carding-engine. Artificial silk can be added.

Apparatus for singeing cloth. ALBERT N. OTIS (to General Electric Co.). U. S. 2,011,333, Feb. 5.

Gas-proof fabrics. G. CARDILE (trading as Industria Articolli Caoutchouc I. A. C.). Brit. 292,813, Sept. 23, 1927. A fabric is coated with animal glue rendered supple by addition of glycerol and insol. by a dichromate, CH_3O or other suitable reagent, and is coated on both sides with a thin layer of rubber or like material, which is vulcanized.

Recovery of volatile solvents. MARIUS BLANC. Fr. 643,716, Nov. 10, 1927. Volatile solvents used in *calendering* or otherwise *treating cloth* are recovered by a hood of approx. hemispherical or conical shape, the walls of which are cooled.

Purifying benzine after use in "dry cleaning." J. J. WACK. Brit. 292,433, Jan. 15, 1928. The benzine is centrifuged and then injected in a finely atomized state to an alk. soln. which contains Na_2CO_3 or K_2CO_3 , NaCl or other neutral compd. esp. the emulsion, and an alk. bleaching agent such as Ca hypochlorite. The soln. is covered with a viscous layer such as glue through which the benzine alone passes. An app. is described.

Stable and solid solutions of sulfonic acids. I. G. FARBENIND. A.-G. Fr. 643,062, Sept. 27, 1927. The alkali salts, particularly the NH_4 salts, of alkylated or cycloalkylated natic sulfonic acids are dissolved in org. solvents to obtain stable solid solns. for use in the *textile industry* as purifying agents, etc. In examples, Na butylnaphthalenionate (from C_{10}H_8 , BuOH and ClSO_3H) and dipentene (waste from the manuf. of amphor from oil of turpentine) are worked together at 90° in a mixer and pressed on into bars. The product acts as a soap for textiles, etc. Na isopropylnaphthalenionate gives with dipentene and $(\text{NH}_4)_2\text{SO}_4$ a product useful as an auxiliary in the dyeing of wool. Dipentene may be replaced by 1,3-dihydroxybutane, or tetrachloroethane.

Chinese wood oil. V. Crazing and folding during drying. A. FIBNER AND E. ROSSMANN. *Tech. Hochschule München. Chem. Umschau, Fette, Oele, Wachse u. Harze* 35, 281-90(1928); cf. *C. A.* 23, 291.—Microscopic examn. of exptl. films on glass of Chinese wood oil revealed a shrinkage in vol. and the formation of fine cracks while the film was still moist, the cracks reaching through to the bottom. This contraction coincides with the formation of β -eleostearin from the α -variety by polymerization or condensation. The next step in drying is the formation of folds at right angles to the cracks, increasing the vol. and frequently pushing the cracks together again to form a double-lipped joint; this folding coincides with the absorption of O_2 by α -eleostearin. Opposed to this view are the facts that β -eleostearin alone, when melted, will show contraction and crack formation, and also that the drying curves of β -eleostearin indicate primary oxidation, followed by polymerization. Drying the films in the dark always prevents wrinkling and clear films are obtained. In the light of the quartz lamp wood oil never dries clear; in sunlight at lower temp. simple wrinkling occurs without cracking; α -eleostearin does not appear to cause cracking at room temp. It has also been observed in a black wood oil varnish that a network of fine cracks can form after the wrinkles appeared, passing through the wrinkles at all angles. P. ESCHER

Modern solvent and plasticizers. Their use in lacquers. A. BOAKE, ROBERTS AND CO. *Times Trade and Eng. Supplement* (London) 23, 36(1928).—There may come a time when paints, as known for so many years, will be completely replaced by cellulose lacquers. E. M. SYMMES

Further recent progress in the production of resinoids. CARL MARX. *Plastics* 4, 554, 566, 618, 633(1928). E. H.

Pressureless molding of resinoids. CHARLES W. RIVISE. *Plastics* 5, 9 11, 24 (1929).—A review of patents. E. H.

American naval stores. The steam solvent process. R. W. CORNELL. *Times Trade and Eng. Supplement* (London) 23, 55(1928).—A review of the industry, also pointing out a recent advance in the production of light-colored wood rosin, hitherto impossible. E. M. SYMMES

Ti salts and pigments (ANON) 18. Determination of As in oxide of Sb pigment (SRROIS) 7. Acid-proofing chemical apparatus with synthetic resins (Brit. pat. 292,334) 1. Colloidal dispersions (Brit. pat. 292,965) 13. Pyroxylin compositions (U. S. pat. 1,702,181) 23. Drying rubber articles (Brit. pat. 293,061) 30. Cleaning steel preliminary to painting it (U. S. pat. 1,700,739) 9. Zn (Fr. pat. 643,483) 9.

Paint. E. I. DU PONT DE NEMOURS & CO. Fr. 643,709, Nov. 9, 1927. Coagulation in paint contg. siccative oil is prevented or suppressed by the addn. of 0.1% or more of an acid of the citric, malic and tartaric group.

Water paint. ALFRED P. GOODELL and GARDNER W. TARR. U. S. 1,700,404, Jan. 29. A mixt. is formed including a casein solu., lithopone, clay and paper-maker's wax in such proportions that when dild. with water a spreadable coating compn. is obtained which forms a quick-drying, permanently white film of good white light reflective power and good covering or hiding power.

Paints and varnishes with a vehicle containing rubber. CHARLES M. A. STINE, COLE COOLIDGE and EDMUND B. MIDDLETON (to E. I. Du Pont de Nemours & Co.). U. S. 1,700,778, Feb. 5. An aromatic hydroxy compd. such as hydroquinone is used for counteracting the viscosity-reducing action of driers and pigments on rubber-contg. vehicles in the presence of air.

Roller mill suitable for grinding paints. J. R. TORRANCE and TORRANCE & SONS, LTD. Brit. 292,431, Jan. 3, 1928.

Pigments. FRANK RAHTJEN and MANFRED RAGG. Fr. 642,966, Oct. 25, 1927. Masses contg. metallic powders, particularly Pb, such as pigments for paints, are made

by applying the metals to powd. or liquid substances heated a little beyond the solidification point of the metal, and suitable for use as addns. to paints or colors; the substances are preferably kept in movement. The application is made by pulverization in the fused state and with exclusion of air, or in the presence of air followed by a partial reduction.

Inks. I. G. FARBENIND. A.-G. Brit. 292,655, March 16, 1927. Products such as stamping, copying and hectograph inks contain coloring substances together with sorbitol or its dehydration products or derivs. such as acetylsorbitol, together with various other (usual) ingredients. Several examples are given.

Printing inks. J. AZZOPARDI. Brit. 293,238, Sept. 29, 1927. A petroleum asphalt or pitch obtained as a residue after steam distn. is used with light mineral oils such as "mineral turpentine" in making newspaper inks or the like, forming the main part or all of the vehicle. Other substances may be added, such as turpentine, colophony and Mn resinate for producing inks of better quality.

Treating coatings of cellulosic derivatives. T. T. JUNIOR. Brit. 293,214, Aug. 6, 1927. A soln. of alc. contg. ether and castor oil is applied between or after applications of "cellulose paint" or varnish, and the surface may be finally polished by use of a "partial solvent" of the coating.

Mastics, varnishes, etc. I. G. FARBENIND. A.-G. Fr. 642,799, July 6, 1927. Mastics on coatings for prepg. groundwork to be painted or varnished contains cellulose esters other than nitrocelluloses or ether oxides of cellulose or nitrocelluloses which are insol. or only slightly sol. in the solvents for the varnishes to be applied to the prepd. groundwork. Natural or artificial resins insol. in the said solvents may also be added and mineral substances insol. in water such as silicates, carbonates, oxides or SiO_2 , kieselguhr, powd. stone, whiting, ocher, etc., and substances such as graphite, talc. or mica and org. colors.

Colored lacquers. I. G. FARBENIND. A.-G. Brit. 293,067, Feb. 24, 1927. Colored masses comprising cellulose esters or ethers, artificial or natural resins or their solns. such as lacquers or varnishes are prepd. with salts formed by dyes contg. sulfonic or carboxylic groups with org. derivs. of NH_2 in which the ammonia N atom is not bound to such a C atom as is itself directly connected with 2 other atoms of N. Suitable bases are alkylamines and their derivs., such as ethylamine and di- and tri-ethanolamine; arylalkyl- and aryl-amines such as dimethylaniline, xylidine and pseudocumidine; hydro-aromatic amines such as cyclo- and dicyclo-hexylamine; heterocyclic bases such as pyridine, piperidine and quinoline; and bases of dyes such as those of the triphenylmethane, azine, thioazine and oxazine classes. Several examples are given.

Pyroxylin composition. ROBERT CALVERT (to Van Schaack Bros. Chemical Works). U. S. 1,702,151, Feb. 12. The acetate of methylisobutylcarbinol and a smaller proportion of the monoethyl ether of ethylene glycol are used as solvents in making compns. suitable for use as *lacquers*.

Synthetic resins. BRITISH THOMSON-HOUSTON CO., LTD., H. W. H. WARREN, R. NEWBOND and A. T. WARD. Brit. 292,646, Feb. 25, 1927. Products of the "glyptal" type are hardened by heating the fusible resin, first at 220–300°, then at 170–200° or (for a longer time) at 135–170°, followed by final molding under pressure at 120–170°. Some modifications and details of molding are described.

Synthetic resins. R. W. BELFIT (to Scovill Mfg. Co.). Brit. 292,912, June 25, 1927. Products derived from N-contg. substances such as urea, thiourea or their derivs. such as benzoyl- or acetyl-carbamide, cyanamide, guanidine or their active derivs., such as the products derived from these substances by condensation with CH_2O or the like, are rendered of greater "chemical-resistivity" by addn. of substances such as salicylic acid, acetylsalicylic acid, salicylamide, salicylates of NH_4 , Sr or Mg, gallic acid, hydro-naphthoic acids, hydroxybenzoic acids, benzoic, phthalic and anthranilic acids, succinic and oxalic acids. These addns. preferably amount to 15% or more of the wt. of the N-contg. substance used. The products are suitable for use in plastic compns. or *lacquers*, and many details and examples are given.

Synthetic gum or resin. CANADIAN ELECTRO PRODUCTS CO., LTD. Fr. 643,419, Nov. 7, 1927. Gums or resins are produced by reaction of vinyl esters, such as the acetate or formate, with aliphatic or aromatic aldehydes, preferably AcH or CH_2O ; e. g., 4–15 parts of AcH is heated to 100° under pressure with 100 of vinyl acetate for 6 hrs. A small quantity of a catalyst such as HCl may be added.

Phenolic resins. BAKELITE CORP. Fr. 643,438, Nov. 7, 1927. A resinous compn. is produced by causing a phenol to react with CH_2O in excess and combining at least a part of the excess with urea or other compd. capable of forming a non-phenolic resin. The first reaction is carried out in the presence of a basic catalyst and the second in the

presence of an acid catalyst. Thus, phenol is heated with a soln. of an excess of CH_2O in the presence of Na_2CO_3 till the water seps., preferably under reduced pressure. Urea with a quantity of lactic, boric or phosphoric acid, sufficient to make the mass acid, is added and the heating continued. If a varnish or lac is required, alc. or other solvent is added before or after the urea. Derivs. of urea or *p*-toluenesulfonamide may be used instead of urea. Fr. 643,439, describes the prepn. of a resin from phenol and anhydroformaldehyde-aniline, which is hardened by removing the PhNH_2 . A catalyst such as hexamethylenetetramine may be used.

Urea-formaldehyde resins. KURT RIPPER (to Fritz Pollak). U. S. 1,701,986, Feb. 12. Articles comprising a urea- CH_2O resin are dried in molds formed at least in part of, or coated with a cellulose ester.

Condensation products of alcohols and ketones with urea, etc. I. G. FARBERMUND A.-G. Brit. 292,595, June 24, 1927. Condensation products prepd. as described in Brit. 278,390 (C. A. 22, 2673), Brit. 280,238 (C. A. 22, 3056), Brit. 287,095 (C. A. 23, 533) and Brit. 290,192 (C. A. 23, 852) are treated with CH_2O or with a substance yielding CH_2O , to produce viscous liquids or resinous solids. Several examples are given.

Condensation products of amino compounds with acetylene. SOCIÉTÉ ANON. POUR L'INDUSTRIE CHIMIQUE À BAËLE. Brit. 292,168, June 16, 1927. Aniline or a similar amino compd. is treated with C_2H_2 in the presence of a catalyst such as a Hg compd. Resinous products are obtained which may be used in making lacquers and varnishes or as vulcanizing assistants, wetting agents, fiber-protecting agents or reserves in the textile industry, and may be converted into new products by sulfonation, nitrosation, nitration, reduction, etc.

Phenol-aldehyde condensation products. G. BIA and J. E. D. DE GRANVILLE DE BIELIZE. Brit. 292,629, Jan. 17, 1927. A mixt. of phenol or *m*, *p*-cresol with considerably more than an equimol. proportion of CH_2O and with a catalyst is heated to the b. p. for not more than 1 hr.; the mixt. is then cooled to about 50° , the catalyst (if alk.) is neutralized and the mixt. is allowed to stand; the liquid resinous product is sepd., heated to above 100° and finally molded at 90 – 112° . Either opaque or translucent products can be obtained according to variations in details of the process, which are described.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Total fat determination in sulfonated oils. W. HERBIG. *Seifensieder-Ztg.* 55, 419–21(1928).—Turkish red oils are used in the textile and leather industry, with different requirements for each. The following remarks refer to textile oils only. The various Turkish red oils are sufficiently similar for unified definitions and analytical methods. Sulfuric acid is the essential constituent and the amt. of org. SO_3 detn. the quality of the oil. The volumetric method and the beeswax-cake method are not accurate. While the per cent of total fat is important, the "wetting" ability and the resistance against lime, MgSO_4 and lye are more important. These properties are functions of the % of org. SO_3 . "Monopol" soap has 71.5% total fat and 6.43% org. SO_3 ; "Avirol K M Extra soap has only 37% and 4.5%, resp.; but the degree of sulfonation for "Monopol" is only 30% and for "Avirol" 51%, and since the latter's stability toward acid and lime is greater than the former's it is superior notwithstanding "Monopol's" higher % of total fat. A new method for total fat detn. is uncalled for. The important considerations are: (1) which properties of Turkish red oils constitute their value and (2) which constituents produce these properties.

A new process for candle making. L. LINDNER. *Seifensieder-Ztg.* 55, 436(1928).—A short description of Grabec's patented method for producing, by machine, both church candles and ordinary candles.

The fermentation method of fat splitting. EMIL HOYER. *Seifensieder-Ztg.* 56, 1–2(1929).—Some factory data are given with explanatory remarks.

The Wijs method as the standard for iodine absorption. J. J. A. WIJS. *Analyst* 54, 12–4(1929).—At the 9th Intern. Union of Pure and Applied Chemistry at The Hague, the Wijs method was recommended as the official method for detg. I values. Papers by Schmidt-Nielsen and by Weiser and Donath have made statements which would appear to cast doubt with respect to the W. method. Here the objections are discussed and explained. Some details are given amplifying the usual directions for carrying out the method.

W. T. H.

Extraction of oils and fats. Presses and solvent machines. ERNEST FYLEMAN. *Times Trade and Eng. Supplement* (London) 23, 36(1928).—A review. In the Simon extractor (illustrated) the material to be extd. is placed in cylindrical cages between 2 end plates and extd. by oil solns. of 3 different concns., finally with pure solvent, followed by steaming, all automatic. The time required was 20-25 mins. A very pure product was obtained at low cost and without skilled supervision. E. M. SYMMES

A simplification in refining edible oils. R. DIETERLE. *Seifensieder-Ztg.* 55, 428-9(1928).—(Illustrated.) Instead of washing the oil after settling the soap stock ("foots"), there is added to the oil some asbestos fiber, and the oil is then filtered through a special press where the asbestos is deposited as a paper-thin film, retaining all the remaining impurities. P. ESCHER

Determination of organic SO_2 in sulfonated oils by the "American method" with normal sulfuric acid. W. HERBIG. *Seifensieder-Ztg.* 55, 427-8(1928); cf. C. A. 22, 743, 1298.—A reply to Bauer (C. A. 22, 2074) who claims that HSO_3 is the radical titrated in the detn. of org. SO_2 in sulfonated oils. H. claims that the org. SO_2 is liberated as H_2SO_4 during boiling with the titrated acid and that the calcn. must therefore be made on the basis of $\text{H}_2\text{SO}_4 = 2\text{KOH}$, instead of one KOH. P. ESCHER

Negative catalysts and β -naphthol as a medium for preventing spontaneous combustion of oily textile fibers. H. POMERANZ. *Seifensieder-Ztg.* 55, 207-8, 214-5 (1928).—The presence of an autocatalyst of peroxidative character is assumed in cases of oxidation of olein to a stage of spontaneous ignition. β -naphthol reduced the self-heating by permitting only a portion of the olein to oxidize, similar to mannitol in preventing the oxidation of NaHSO_3 ; it is not proven that β -naphthol prevents ignition. P. ESCHER

The oils, fats and soap industries in 1928. REX FURNESS. *Ind. Chemist* 5, 15-7(1929). E. H.

Manufacture of automobile soaps. A. J. REDPAR. *Soap* 4, No. 3, 29, 77, 79 (1928).—Methods are given for making potash and soda soaps which are suitable for washing automobiles. E. SCHERUBEL

Determination of sodium carbonate in soaps and soap powders. W. PRAGER AND W. SCHAEFFER. *Seifensieder-Ztg.* 56, 8-9(1929).—(Illustrated.) The method described is similar to W. F. Hillebrand's in "Analysis of Silicate and Carbonate Rocks." Comparison with results by the Geissler app. shows the latter to give low values. P. E.

Soap lather. L. ZAKARIAS. *Z. physik. chem. Seifenforsch.* 1, 66-70(1928).—Some data are given on the influence of size of vessel, amt. of soln., duration of shaking, age, temp. and concn. of soap soln. upon the vol. and consistency of soap lather. P. ESCHER

Jellying of soaps. J. HERRTES. *Z. physik. chem. Seifenforsch.* 1, 70-2(1928).—By means of Luer's pektinometer (C. A. 21, 3007) the jelly strength of 1.5% soap solns. was measured and H. tabulates the results. No conclusions are drawn. P. E.

Determination of the detergent value of washing media. KARL LÖFFEL. *Seifensieder-Ztg.* 56, 7-8(1929).—L. proposes some fundamental definitions and formulates the detergent value X as follows:

$$X = \frac{\text{washing effect}}{\text{degree of damage}} = \frac{\text{condition} + \text{surface tension} + \text{inner friction} + \text{foam number}}{\text{free alkali} + \text{factor in damage to dyes} + \text{factor in fiber damage}}$$

Washing compds. should be grouped according to their use and each group should have such testing methods as will show their fitness for such use: (1) Compds. for body-care: toilet soaps, disinfectant soaps, etc. (free alkali detn. and surface tension). (2) Cleansing compds. for textiles (surface tension, inner friction, foam no., free alkali, damage to dye and fiber). (3) Cleansing compds. for wood and metal (surface tension, free alkali, abrasives, mineral oil, rosin, lampblack, etc.). P. ESCHER

Ravon oils (MULLIN) 25. Oils obtained from insects (TSUJIMOTO) 111. Device for gravity separation of oil from water, etc. (Brit. pat. 293,091) 1. Dehydrating oils, fats, etc. (U. S. pat. 1,701,092) 13.

Fatty substances. RAYMOND VIDAL. Fr. 33,235, Feb. 18, 1927. Addn. to 637,274 (C. A. 23, 536). Fatty substances sol. in water are prepd. by treating sulfonated fatty acids such as sulfo-oleic, and sulfonated oils or vegetable and animal oils, waxes, etc., with alkali hypochlorites.

Fatty acids. GASPARE MICHELINI. Fr. 642,653, Oct. 21, 1927. Clear transparent fatty acids are obtained by decompn. of the sapon. paste below the b. p. and treating the acids with oxidizers in an acid soln. sufficiently dil. to avoid an appreciable increase of temp. or liberation of Cl or O in the form of bubbles.

Apparatus for fat extraction by use of solvent in vapor form under reduced pressure. A. PANSKY. Brit. 293,176, June 2, 1927.

Macerating fatty tissue and rendering and filtering fats. PERFECTION CO. Brit. 292,719, April 4, 1927. An app. is described.

Extracting oils and fats from waste animal and fish material, etc. J. LEWIS. Brit. 292,327, Dec. 22, 1926. The material is heated during maceration, further heated in a sep. chamber to above 100° and finally treated in a centrifugal separator while jets of steam, hot air or the like are directed onto it. An arrangement of app. is described.

Oil extraction press. JOHANNES JAKOBSEN. Fr. 643,657, Nov. 8, 1927. Constructional details are given.

Sulfonating oils. ERBA A.-G. Brit. 292,574, June 23, 1927. Oils are sulfonated by H_2SO_4 in the presence of substances giving off O in acid soln. such as H_2O_2 , alkali or alk. earth metal peroxides, persulfonic acids, alkali persulfates, percarbonates or perborates, peroxides of org. acids such as acetyl peroxide or benzoyl peroxide or compds. of H_2O_2 with org. substances such as benzoic acid or urea. The products are preferably neutralized directly without previous washing and the sulfates may be thrown down by the addn. of alcs. such as EtOH, MeOH or iso-PrOH.

Soap. ARTHUR H. CHARLTON and T. B. ROWE & Co., LTD. Ger. 470,161, Nov. 3, 1926. See Brit. 267,999 (C. A. 22, 1246).

Soap. XAVIER DURTHALLER and PAUL AUBIN. Fr. 643,672, Nov. 9, 1927. An app. is described for cleaning the bottoms of soap-making boilers without interrupting the manuf.

Soap. PERCY H. GRANT (to the Nemo Manufacturing Co., Ltd.). Can. 286,324, Jan. 8, 1929. To a mixt. of 2.25 lbs. stearic acid, 4.5 lbs. coconut oil and 6.5 lbs. of some other vegetable oil, as soy bean, cottonseed, or linseed, is gradually added, with stirring, a soln. of 1.5 lbs. KOH and 1.25 lbs. NaOH in 3 gal. water. The mixt. is heated to boiling until sapon. is complete. Five lbs. Na_2CO_3 in 1 gal. hot water is gradually added; the product is neutralized, if necessary, with oleic acid and poured, while still hot, over 40 lbs. finely sifted sawdust. After thorough mixing the product is dried in warm air until it can be pulverized.

Soaps from low-grade fats. JOEL STARKELS. U. S. 1,701,703, Feb. 12. Low grade fats contg. material of high I no. are converted to esters (suitably by use of MeOH or EtOH with HCl and $CaCl_2$) and the esters are distd., partially hydrogenated and the hydrogenated product is saponified.

28—SUGAR, STARCH AND GUMS

F. W. ZERBAN

The work and the development of the sugar industry in the field of machinery and apparatus from 1919 to 1926. ERICH GUNDERMANN. *Chem. App.* 15, 3-4, 27-8, 62-3, 85-6, 114-5, 125-6, 220-2, 254-7, 266-8(1928); 16, 4-5(1929).—A general review with 25 cuts and many references.

J. H. MOORE

The yield of raw sugar. K. ŠANDERA. *Listy Cukrovar.* 47, 174(1928).—A discussion.

FRANK MARESH

Correct procedure in sulfitation of thin (sugar) juice. I. Sulfitation. E. THIELE PAPE and P. MEIER. *Z. Ver. deut. Zucker-Ind.* 1928, 233-41.—In order to test the relative merits of sulfitation before the second carbonatation and of simultaneous treatment with SO_2 and CO_2 , the amt. of sulfite remaining in soln. in either case has been studied. Solns. of lime, with and without sugar, and limed juices, were treated with known amts. of SO_2 and CO_2 by both methods. Successive treatment removed a distinctly larger amt. of sulfite than simultaneous treatment.

B. C. A.

Clarification of diffusion juices with dolomitic lime and aluminum hydroxide. VÁCLAV KOHN. *Listy Cukrovar.* 47, 147-62(1928).—Purification of raw beet juices with an addn. of 0.7-0.9% per vol. of "calcium aluminate" during digestion and satg. with CO_2 or SO_2 at 80° resulted in a juice of better color and quality than juice from a French satn. with 2.5% CaO. CO_2 is better than SO_2 . Filtering raw juices with an addn. of 0.6-0.8% CaO per vol. and satg. with gaseous CO_2 and an equiv. amt. of

caked $\text{Al}(\text{OH})_3$ resulted in a soln. with the same color, clarity and sucrose content as when treated by the French method with 3.25% CaO . Satn. of raw juices in which 0.25–0.5% CaO was replaced by an equiv. amt. (0.152–0.303% Al_2O_3) in the form of $\text{Al}_2(\text{SO}_4)_3$ resulted in fluids of the same quality, clarity and ash content, but much higher in color than when 2.75–3.0% CaO was used alone. The $\text{Al}_2(\text{SO}_4)_3$ has no effect upon the compn. of sugars in soln. When more than 0.5% CaO was replaced by an equiv. amt. (0.303% of Al_2O_3) in the form of $\text{Al}_2(\text{SO}_4)_3$, the CaSO_4 passed into the satd. soln. in larger quantities (from 0.084% to 0.193% CaO). Diffusion liquors, when 0.2–0.5% CaO was replaced by $\text{Al}_2(\text{SO}_4)_3$ (as 0.121–0.303% Al_2O_3), showed an equal clarity but less color than when 2.25% CaO was used alone. When 0.4–0.5% CaO was replaced by the equiv. $\text{Al}_2(\text{SO}_4)_3$ (as 0.242–0.303% Al_2O_3), the juices contained a larger amt. of CaSO_4 than when 2.0–2.5% CaO was used alone; this increase was from 0.143% to 0.182% CaO . When 0.2–0.3% CaO was replaced by $\text{Al}_2(\text{SO}_4)_3$ having the equiv. 0.121–0.182% Al_2O_3 , the amt. of bound Ca was the same as when 2.5% CaO was used alone. In all expts. the soln. was satd. with CO_2 . The best clarity was obtained when the full amt. of $\text{Al}_2(\text{SO}_4)_3$ was added and the soln. was satd. fractionally with CO_2 . Satn. of the soln. in the presence of $\text{Al}_2(\text{SO}_4)_3$ required less time for the $\text{Al}_2(\text{SO}_4)_3$ also sats. the soln. (with SO_4). The presence of $\text{Al}_2(\text{SO}_4)_3$ permits a more rapid filtration. The $\text{Al}_2(\text{SO}_4)_3$ may be anhyd., cryst. and the presence of Fe_2O_3 is not detrimental to the process. FRANK MARESH

Description of sugar cane varieties (Java). XV. The most important "Royalty" varieties. O. POSTHUMUS. *Arch. Suikerind., Mededeel. Proefsta. Java Suikerind.* III, 949–75(1928).—These varieties, which are described in detail, are mostly crossings of noble canes; they are susceptible to scab and mosaic and have a weak root system. They are inferior to the modern P. O. J. varieties, especially No. 2878

P. R. PEKELHARING

Physical-chemical research in the sugar beet industry. KAREL ŠANDERA. *Chem. (Ožor 3, 339–42(342 English))(1928).*—Phys.-chem. investigations applied to the beet sugar industry have undoubtedly contributed enormously to greater economy, better operation control and perfection of sugar manuf. as shown in diagrams by the Research Institute of the Czechoslovakia Sugar Beet Industry at the Exposition of Contemporary Culture in Brno.

JAROSLAV KUČERA

The De Vecchis method of drying beets. ARNOLD KUHNER. *Listy Cukrovar.* 47, 180–4(1928).—A statistical study.

FRANK MARESH

Variations in the composition of sugar beets during the harvesting period. J. ZAMARON. *Bull. assoc. chim. suc.* 45, 448–9(1928).—From numerous analyses of roots pulled at various dates between Sept. 20 and Nov. 20, 1927, in the neighborhood of Soissons and Laon, graphs were constructed showing the changes in compn. of the roots in the ground during this period. The av. wt. of the roots diminished from 615 g. to 580 g. between Sept. 20 and Oct. 28, then increased to 660 g. by Nov. 12, the weather being favorable to ripening, and finally decreased to 590 g. by Nov. 20, owing to rainy weather. The sucrose content (by hot aq. digestion) increased from 16.2% on Sept. 20 to 17.2% on Oct. 12, and further to 17.4% on Nov. 11, after which date it fell rapidly to 16.8%. The quotient of purity fell continuously from 88.5 on Oct. 12 to 83.5 on Nov. 20, during which period the amt. of reducing sugar increased steadily from 0.25 to 3.5% of the sucrose. The optimum condition was attained on Oct. 12, when the purity was a max. and the amt. of reducing sugars normal. B. C. A.

Studies on the occurrence of methanol and ethyl alcohol in beets. M. JEDLIČKA. *Listy Cukrovar.* 47, 175–80(1928).—Previous studies showed that both MeOH and EtOH occur in the condensor liquors at sugar mills. Both MeOH and EtOH are found in the liquors throughout the process of sugar extn.; the combined amounts range from 0.00085% in the discarded water to 0.008% in the beet juice. Beet shavings show a content of combined alcs. of 0.0019% while beet mash contains 0.020%. During a digestion of beet shavings with lime, both alcs. are evolved in approx. equal quantities although according to the present concept of the compn. of beet pectins, only MeOH should form. The pectin of the treated beets contained both alcs. as a unit of structure.

FRANK MARESH

Comparative experiments with beet seeds. JAROSLAV SOUČEK. *Listy Cukrovar.* 47, 187–210(1928).—From expts. with seeds from 8 seed dealers who supply their seeds to Czechoslovakian growers S. concludes that the domestic beet seeds were equal to the best imported both in yield and sugar content.

FRANK MARESH

Diffusion battery technic. J. HAMOUS. *Listy Cukrovar.* 47, 173(1928).—The last extn. with a density of 1° Bg. without regard to the sugar content of the remaining beets is the limit of economical diffusion; juices with a lower density cannot be evapd. economically enough, for the sugar content is too small.

FRANK MARESH

The question of pressure evaporation. JANKO PROCHÁZKA. *Listy Cukrovar.* 47, 145-6(1928).—From the last campaign, P. shows that vacuum distn. colors the soln. much less than pressure evapn. and is therefore more favorable to use in making white sugar from heavy liquors. Both processes were tried on a com. scale. F. M.

Pressure evaporation in Zidlovice. JAROSLAV TIETZ. *Listy Cukrovar.* 47, 184-6(1928).—Data covering three seasons are given with the conclusion that with pressure evapn. the quality of sugar is not impaired. FRANK MARESH

Pressure evaporation. F. TUREK AND K. SÁZAVSKÝ. *Listy Cukrovar.* 47, 221-3(1929).—A critical analysis of the paper by Janko Procházka (2nd preceding abstract) showing that the statements hold for the local mill only. Data for both pressure and vacuum evapn. in mills of the authors show no dark-colored product encountered in pressure evapn.; sugar solns. evapd. under pressure were lighter in color than those evapd. in vacuum. Fuel economy is greater for pressure evapn. FRANK MARESH

Pressure evaporation. A. SCHULZE. *Listy Cukrovar.* 47, 224(1929).—A report from an Austrian mill using pressure evapn. and producing white sugar from heavy liquors since 1923 without any difficulties. FRANK MARESH

Nutritional contents of sediments in settling basins. JOSEF NOVÁK. *Listy Cukrovar.* 47, 219-21(1929).—Sediments from settling basins of sugar mills located in central Bohemia were analyzed chemically and physiologically. Vessels were filled with mixed loam, sediment from sugar mill and glass blower's sand in the ratio $\frac{1}{2}$ kg., $\frac{1}{2}$ kg. and 5 kg., resp., and planted with oats. Three vessels were fertilized with N, P and K; the next three with all but N, the next with all but P and the last with all but K. A control growth of oats was grown upon loam and sand in the ratio $\frac{1}{2}$ kg. and 5.5 kg. The amount of elements in the sediment according to chem. analysis is: N 0.03%, P_2O_5 0.28%, K 0.14%. The amount of elements absorbed by the plant from the sediment is only N 0.004%, P_2O_5 0.00%, K 0.046%. The percentage of elements absorbed from the sediment is: N 13, P_2O_5 0.00%, K 33%. The analysis of the loam used showed N 0.004%, P_2O_5 0.017%, K 0.028%. The plant uses 13% of the N, 33% of the K and none of the P found in the sediment; the latter is due to the presence of lime. FRANK MARESH

The properties of kieselguhr. P. HONIG AND M. VAN DE KREKE. *Arch. Suikerind Mededeel. Proefsta. Java Suikerind.* III, 977-90(1928).—The uses of kieselguhr as a filtration aid and clarifying agent are discussed. In Java its use is indicated principally for the filtration of muds, and of melted sugars. It may also be used on thick juices and run-offs, but this requires rather large quantities. The properties of 6 kinds of kieselguhr are described. Not only the phys. condition of the material, but also its chem. compn., are of great importance. The results of analyses show that the best brands contain little or no Al, and only very small quantities of Fe sol. in HCl; org. matter is practically absent. Methods of analysis are given in an appendix. P. R. P.

Manufacture of cornstarch, the utilization of its residue and the recovery of corn oil. II and III. O. K. A. KRIZKOVSKY. *Chem.-Ztg.* 52, 466-7, 486-7(1928); cf. C. A. 22, 3313, 4863.—Descriptive. A. L. HENNE

Quantities of fertilizers used in the year 1927, and their distribution over the area planted (Java) (HEYLIGERS) 15. The behavior of the Sb electrode in buffered and unbuffered solutions (LAVA, HEMEDÉS) 2. Methods of determination of H-ion concentration, and their application in sugar manufacture (KUKHARENKO, SAVINOV) 2. The viscosity of supersaturated solutions (TAIMNI) 2. Determination of the catalytic coefficient of the OH ion in the mutarotation of glucose and lactose (LOWRY, WILSON) 2. Preparation of triacetyl starch and its molecular weight (TSUZUKI) 10. Apparatus for liming sugar juices or mixing other materials (U. S. pat. 1,701,164) 1. Evaporators for sugar solutions, etc. (Brit. pat. 292,915) 1. Carbonaceous product from electric furnace treatment of carbonized lignin residues (U. S. pat. 1,701,272) 18.

Sugar. BERNARD H. VARNAU and TRUMAN B. WAYNE. Fr. 642 854, Oct. 11, 1927. Fine-grained soft cane sugar is obtained from the sirups remaining after the purging of hard, granulated massecuites without reboiling the sirups in vacuum pans, by heating to remove any false grain, forming small crystals by cooling rapidly with or without the addn. of seed crystals, and keeping the mass in slow, continuous agitation during crystn.

Sugar. WILLIAM K. MELROSE and JOHN C. STEAD (to Sugar Beet and Crop Driers, Ltd.). Can. 286,333, Jan. 8, 1929. Sirup extd. from dried beet by diffusion with warm water at 50° to 70° is treated at the same temp. with lime to ppt. the dissolved impurities and to render the sirup slightly alk. The ppt. and suspended im-

purities are sepd. and the liquor is decolorized with activated carbon. The final liquor is filtered, boiled and grained to produce a first strike of white sugar. The green sirup obtained from the first strike of white sugar is reboiled to produce a second strike of white sugar. The green sirup resulting from the purging of the said second strike of white sugar is boiled to produce a second product of raw sugar and the second product of raw sugar is continuously remelted in the said final liquor during the course of manuf.

Sugar from beets. R. G. W. FARNELL. Brit. 293,066, Feb. 23, 1927. Dried beet cosettes are extd. with water at reduced pressure and at a temp. below 100° (preferably 50–60°). The pressure may be varied during the extn.

Polysaccharide degradation. KARL FREDENHAGEN and BURCKHARDT HELFERICH. Can. 286,179, Jan. 8, 1929. Water-sol. degradation products of polysaccharides are formed by the action on a material contg. polysaccharides, without more than 7% of water, of HF contg. less than 20% of water and removed from a previous operation at a temp. below 100°, and removal of the HF after the reaction.

29—LEATHER AND GLUE

ALLEN ROGERS

New glue-testing work. OTTO GERNGROSS. *Gerber* 54, 179–80(1928).—Ten different hide and five different bone glues were examd. in eight different labs. for moisture, ash, p_H , viscosity at different concns. and temps., m. p., solidification point and setting time. The results were uniform. Viscosity of bone glue should be measured at 30° and of hide glue at 40° for comparable results. The system of Ostwald and Kohler for the evaluation of glues by treatment of solns. with sulfosalicylic acid cannot be used to compare hide and bone glues because of differences in effects. Although the rapid methods give fair indications of the joint strengths of hide glues they do not give agreements with bone glue values. G. has shown that exptl. disintegration of gelatin does not always alter viscosity, jelly strength or joint strength in the same order or the same direction. The rapid methods of evaluation are valuable but not for evaluating joint strength or adhesion.

L. F. MAREK

Polishing leather, wood, metal, etc. (Austrian pat. 111,536) 18. Recovery of volatile products (Fr. pat. 643,322) 13. Retort construction for carbonizing scrap leather, etc. (U. S. pat. 1,700,684) 1. Dyes (Ger. pat. 469,946) 25. Emulsifying agents and emulsions (Fr. pat. 33,278) 13.

Tanning. O. ROHM. Brit. 292,501, June 20, 1927. Salts of Fe, Cr or Al are used with H_2PO_4 or acids of As or salts or esters of these acids. Examples are given of the use of Fe sulfate chloride with H_2PO_4 and Na_2CO_3 , and of alum with glycerol, H_2PO_4 and salt. The H_2PO_4 and acids of As may be applied during greasing.

Treating leather, etc. FERDINAND JEAN. Fr. 642,682, Mar. 22, 1927. Animal or vegetable oils are mixed with lecithin and oxidized by a current of warm air and used for dressing skins, currying leather, and for the prepn. of moellon.

Waterproofing leather. E. D. VAN TASSEL and VAN TASSEL CO. Brit. 293,062, Jan. 31, 1927. A compn. for waterproofing leather is prepd. by admixture with paraffin of 5–30% of rubber or guta percha or the like at a temp. of 150° or higher, with or without various other ingredients such as gum, thus, gum sandarac, gum yacca, rosin or cumarone resins, japan wax, montan wax, or linseed or tung oil or resin oil. The mixt. is preferably applied to leather at a temp. of about 95–98°. Cf. C. A. 22, 3616.

Apparatus for applying varnish to hides, drying them and treating them with ultra-violet rays. ELIAS L. ELLIOTT (to Turner Tanning Machinery Co.). U. S. 1,702,043, Feb. 12.

Artificial leather. ANTONIO FERRETTI. Austrian 111,535, July 15, 1928. Pulped rabbit skin waste or the like is mixed with crude latex and the mass rolled out.

Chromate recovery from waste materials. AUGUST TREUSCH and RICHARD WÜRTENBERGER (to J. Mayer & Sohn). U. S. 1,700,657, Jan. 29. Cr-bearing wastes from the leather industry are treated (suitably by use of BaO_4) to convert the Cr into an insol. chromate and the latter is sepd. from the soln. and converted into a sol. chromate, as by use of Na_2SO_4 and HCl.

Increasing the waterproof quality of set glue. HENRY L. PRESTHOLDT. U. S. 1,701,763, Feb. 12. Glue used on porous materials such as casein glue used in making plywood is treated with a fluid glue coagulant such as CH_3O gas or soln. which is applied through the pores of the material.

Glues. C. KLINGSPOR. Brit. 293,232, Sept. 9, 1927. A glue dissolved or steeped in water is treated with a condensation product of a phenol and CH_3O , either as a "condensate oil" or in soln., at a temp. not exceeding 75° . In use, the product is applied and then heated to 145° or somewhat higher.

Rubber. KURT H. MEYER AND H. MARK. *Ber.* 61B, 1939 49(1928).—New and very careful measurements on x-ray diffraction patterns of stretched rubber give, as the dimensions of the unit, a rhombic cell $a = 12.3 \pm 0.1$, $b = 8.3 \pm 0.1$, c (fiber axis) $= 8.1 \pm 0.1$. The space group is V_1 , which specifies 3 two-fold screw axes. It is perfectly clear that the structural mols. form micelles whose form and size may be detd. from the breadths of the x-ray interferences. The av. length of a crystallite is thus 300 to 600 A. U., thickness and breadth 100 to 200 A. U. Since each unit cell contains 8 C_5H_8 groups, the micelle contains 10,000-20,000 unit cells or 80,000-150,000 isoprene groups. In stretched rubber there are long chains contg. 75-150 isoprene groups held together by primary valence forces. These long chains lie parallel to each other along the fiber axis, and the small unit cell represents simply a turn in the screw axis. The olefin character of isoprene accounts for the fact that in unstretched rubber these long chains may contract and spiral, because of the mutual effects of the double bonds. Under these conditions the structure does not permit x-ray diffraction, although the preformed structural units are present. New expts. on the osmotic pressure of dissolved rubber are reported. These results indicate mol. wts. from 150,000 up to nearly 400,000 on account of the very high degree of solvation. Practically all of the benzene or chlorobenzene is bound to the rubber micelles. New expts. are also reported on cold vulcanization with S_2Cl_2 . Rubber shows a close analogy in its reaction to that between ethylene and SCl_2 or S_2Cl_2 to form mustard gas. The compd., $\text{C}_{10}\text{H}_{16}\text{SCl}_2$, is identified. Many of the properties of vulcanized rubber are accounted for in the formation of bridges between double bonds in the same micelle and in the connection between double bonds of different micelles. These new bonds, therefore, decrease the elasticity, and in the limit lead to hard rubber in which the micelles are solidly bound together. G. L. CLARK

Aging of rubber. ALFONS ZELNICEK. *Chem. Obzor* 3, 233-43, 257-63(1928). A discussion of the causes of aging, aging tests, proposals for storing *in vacuo*, in inert gases, under water and chem. means for the preservation of rubber, with a bibliography. JAROSLAV KUČERA

The aging of rubber under tension. GABRIEL G. BALAZS. *India Rubber & Fire Rev.* 28, No. 10, 20(1928); *Gummi-Ztg.* 43, 708, 710.—Mixts. with and without antioxidants were aged under different conditions, while stretched and while not stretched, to det. the influence of the various factors involved on the rate of deterioration. The results are given in tabular form and admit of certain conclusions. In all cases the greatest deterioration occurred with elongations of 0-50%. At 50-100% elongation the aging was the same as with the corresponding unstretched samples. Because of the permanent elongation the tension diminished during the aging periods. The rate of deterioration was not proportional to the initial elongation. The relative rates of deterioration in the hot air oven and in the O-bomb depend upon the presence of antioxidants, the latter rendering the samples relatively more resistant in the O-bomb. The acetone ext., a measure of the chem. changes during aging, increased with the time of aging. It was not proportional to the initial elongation. Because of fatigue phenomena in

the stretched samples, the phys. properties were influenced to a greater extent than is accountable by O absorption alone. A decrease in wt. in the hot air oven indicates that either free S or antioxidant, or both, are volatilized. No definite relations could be found between increase or decrease in wt. and the % elongation. In every case, however, stretching resulted in a slight decrease in wt. The permanent elongation was smaller after aging in the O-bomb than after aging in the hot air oven, so that the samples in the O-bomb were under greater tension than were the corresponding samples in the hot air oven.

C. C. DAVIS

Technical application of antioxidants. E. R. BRIDGWATER. *India Rubber World* 79, 61-2(1929).—A review and discussion, dealing with the characteristics of antioxidants, *reversion phenomena*, *anti-softeners*, *cracking under tension*, *sun-checking* and *methods of testing the aging of rubber mixts.* The view is taken that the term "antioxidant" should be broadened to include all substances which retard the deterioration of rubber, whether this deterioration results from oxidation or from other causes. The tendency toward reversion in overcured mixts is considerably diminished by anti-softeners, for the continued stiffening effect induced by the latter counteracts the softening which sets in after the free S is exhausted. Some compds., e. g., phenyl- α - and phenyl- β -naphthylamine, are very effective in preventing cracking under tension. Used in conjunction with an anti-softener, they are therefore of great value in the numerous types of rubber products which deteriorate on this account. Emphasis is laid on the importance of testing rubber products by some method more closely simulating the performance of the products than the usual methods. These performance tests should be carried out before and after artificial aging in air or in O.

C. C. DAVIS

The isomerization of rubber to cyclorubber under the influence of high-tension alternating currents. GUIDO FROMANDI. *Kautschuk* 4, 185-9(1928).—Substantially the same as C. A. 23, 1009 only in briefer form, with fewer data. **Correction.** *Ibid* 262 Addn. to charts explaining the curves.

C. C. DAVIS

Determination of the iodine number of raw rubber. ADOLF GORGAS. Lab., Ringe Werke A.-G., Berlin-Spandau. *Kautschuk* 4, 253-4(1928).—If in the Wijs-Kemp method for detg. the I no. of rubber (cf. K. C. A. 21, 1901), the ICl-AcOH soln. is replaced by IBr-AcOH, i. e., by Hanus soln. (cf. Z. Nahr. Genussm. 4, 913 (1901)), the reaction at 0° is incomplete. If IBr-AcOH is added to the rubber in CCl₄, coagulation occurs and the reaction is incomplete. At room temp., on the other hand, IBr gives theoretical I values if used under suitable conditions. Replacement of AcOH by CCl₄ is all that is necessary. **Procedure.**—As reagent dissolve 10 g. of IBr in 500 cc. of pure CCl₄. Disperse 0.15 g. of raw rubber in 50 cc. of CCl₄, add 50 cc. of IBr reagent, agitate, let stand 15 min. in darkness, add 30 cc. of 10% KI soln. and 100 cc. of water and titrate with 0.1 N Na₂S₂O₃ until colorless, adding starch near the end point. With vigorous agitation there is no emulsification. From the wt. *s*, the titer *a* of a blank test, the titer *b* of the IBr soln. on titrating back, the *f* of the Na₂S₂O₃ soln. the I no. is calcd. as $(a-b) \times 0.01269 \times f \times 100/s$. Rubber purified from "Revertex" by the method of Pummerer and Pahl (cf. C. A. 22, 885) gave practically the theoretical I no. corresponding to 1 double bond per C₅-H₈ unit.

C. C. DAVIS

Washing hard rubber dust. MAX RATHKE. *India Rubber World* 79, 69(1929); cf. C. A. 23, 307.—A description, with diagram, of a system devised by R. and now in successful operation in Germany.

C. C. DAVIS

Crystallized gutta-percha which is sensitive to light. F. KIRCHHOF. *Kautschuk* 4, 254-5(1928). Tjipetir gutta-percha contg. 98-99% hydrocarbon was purified by extrn. with cold acetone, soln. in CCl₄, filtration and evapn. of the filtrate. The product was white because of a cryst. structure. Microscopically the crystals were rounded, about 0.5 μ thick and 1-1.5 μ long. When the gutta-percha was heated above 43-4°, the crystals disappeared and on cooling reappeared at 42-38°. Fusion and recrystn. could be repeated indefinitely. Exposed to ultra-violet light, the purified product became brittle and more opaque, even in an atm. of H, the changes probably being the completion of crystn. Exposure of purified gutta-percha in C₆H₆ in an atm. of H gave on evapn. a product which was white, unctuous, and fragile, and which m. at 90° to a limpid oil. On cooling, the latter gave a tough product like the original gutta-percha. Heating thus destroyed the cryst. structure. Gutta-percha in an atm. of H irradiated with ultra-violet lost its turbidity at 39-40°, and this reappeared only at 35°, indicating that the m. p. of the micro-crystals of the irradiated product was definitely lower than that of the original crystals. On evapn. of the C₆H₆ this irradiated product redissolved to a clear soln. in C₆H₆, whereas irradiation of a film with air present gave a product which was partially insol. Exposure to ultra-violet light seemed to increase the ability of the gutta-percha to crystallize. In sunlight and air the chief effect was

oxidation. The difference between the behavior of rubber and gutta-perchu in ultra-violet light is attributed to the higher state of polymerization of the latter. Correction. *Ibid* 272.

C. C. DAVIS

Uniting rubber to metal. JOSEPH ROSSMAN. *India Rubber World* 79, 65-8 (1929).—A review and discussion of recent patents, including those for plating with Cu as a binder, the use of bakelite, the manuf. of solid tires, lining metal tanks, metallic fabrics for tires, coating elec. wires and the electrodeposition of rubber. C. C. D.

Fundamental principles of plasticization. JOSEF OBRIST. *Kautschuk* 4, 250-2 (1928); *India Rubber J.* 77, 25-6 (1929).—A review and discussion (cf. Manfred and O., C. A. 21, 2535).

C. C. DAVIS

Causes of variation in plasticity. CEYLON RUBBER RESEARCH COMM. *India Rubber J.* 77, 32-6 (1929).—The present paper deals with tests on crepe rubber 6 months old which had been prep'd. by (1) keeping the coagulum in the serum for different periods before rolling; (2) passing the coagulum through the rollers for different nos. of times; (3) adding different proportions of NaHSO_3 to the latex; (4) coagulating latex after different degrees of diln., and (5) passing dry crepe through different types of rolls to convert it into blanket crepe. The results of the expts. indicate that 6 months after prepn.; (1) crepe prep'd. by machining the coagulum 3 hrs. after coagulation is approx. 80% more plastic than that prep'd. by machining the coagulum 40 hrs. later; (2) crepe is nearly twice as plastic when prep'd. from coagulum machined more than 20 times instead of the customary no. of times; (3) crepe is approx. 50% more plastic when prep'd. from latex contg. no. NaHSO_3 instead of the proportion officially recommended; (4) crepe is only slightly more plastic when prep'd. from very dil. latex than that from concd. latex or from normal latex, and (5) machine-dried crepe may be 50% more plastic than air-dried crepe, and the type of rolls (whether water-cooled or air-cooled) may have an important effect on the plasticity of blanket crepe. The 6 months' storage comprised a short period in Ceylon and 4 months in London, so that the conditions are representative of those normally prevailing in commerce. Both the period during which the coagulum is kept in the serum before rolling, and the proportion of NaHSO_3 may influence the plasticity of com. grades of rubber. Drying crepe in hot air causes considerable increase in plasticity, a fact which is of importance in the prepn. of blanket crepe, and which suggests a reason why smoked sheet is usually more plastic than air-dried sheet.

C. C. DAVIS

Aldehyde derivatives of Schiff's bases as vulcanization accelerators; A-11, A-16, A-19, A-20 and A-50, and the ultra-accelerator Z-88. RUDOLF DITMAR and MANFRED RACHNER. *Kautschuklaboratorium, Graz. Chem.-Ztg.* 52, 935 (1928); cf. C. A. 22, 4876.—Tabulated data show the soly. of the 6 accelerators in water, benzine, C_6H_6 , CS_2 , CCl_4 and EtOH and their behavior with PbO , ZnO , MgO , and CdO , factice, golden Sb, HgS and 3 "Vulkan" colors (cf. D., C. A. 22, 4273).

The accelerator "Tuads" and its limitations. WERNER ESCH. *Kautschuk* 4, 255-8 (1928).—A discussion, with quant. data, of the accelerating properties of "Tuads" (tetramethylthiuramdisulfide), with particular reference to its merits compared with "Thionex" or "Monex" (tetramethylthiurammonosulfide).

C. C. DAVIS

Selenium red, the only red which is stable with all accelerators. RUDOLF DITMAR. *Kautschuklaboratorium, Graz. Gummi-Ztg.* 43, 759-60 (1929).—Tests of the value of Se red in rubber mixts. of widely different types showed that it is of almost unlimited application. It can be used whether alone as a pigment or in conjunction with lithopone, ZnO , TiO_2 , etc. It acts as a plasticizing agent, even when only 3% is added to the rubber, and forms a colloidal soln. with the rubber. It is unaffected by any of the com. accelerators or antioxidants or by factice, and can be used in soft or hard rubber mixts. cured with S. It cannot, however, be used when S_2Cl_2 is used as a curative, either as a vapor or in soln. Its coloring power exceeds that of any other inorg. red pigment.

C. C. DAVIS

A further study of the vulcanization of oils. II. P. STAMBERGER. Univ. College, London. *Rec. trav. chim.* 47, 973-6 (1928); cf. C. A. 22, 506.—Triolein (5 parts) and S (1 part) heated 2 hrs. at 160° yielded a vulcanizate wholly sol. in C_6H_6 . This product digested with acetone (5 parts) for 4 days and the extn. repeated 4 times yielded a residue of increased solidity with diminished soly. in C_6H_6 , and which was slightly elastic. The mol. wts. (detd. in C_6H_6) of the acetone-sol. and C_6H_6 -sol. products were 1204 and 2040, resp. These products were heated at 180° until gelation occurred, under which conditions the C_6H_6 -sol. substance swelled more and formed an insol. product far sooner than did the acetone-sol. substance. When they were exposed at $40-60^\circ$ to ultra-violet radiation in air and in N, the acetone-sol. substance swelled more than did the C_6H_6 -sol. substance, but the latter formed an insol. product far sooner. When the C_6H_6 -

sol. substance was kept under acetone for 3 days, or under water for 8 days, it became elastic and insol. in C_6H_6 . After 3-4 months at room temp. the C_6H_6 -sol. substances became an elastic sticky solid which did not dissolve in cold C_6H_6 but was completely sol. in boiling C_6H_6 , and this latter soln. on evapn. yielded a product sol. in cold C_6H_6 . These results, in conjunction with further swelling phenomena under various conditions, show that the properties of these various substances are altered by soln. It is probable that the low mol. wts. obtained with other gels, such as rubber and cellulose derivs., depend upon a depolymerizing action of the solvents. In the formation of elastic substances from sulfurated triolein, no chem. change takes place, so the change in behavior toward solvents cannot be explained by the formation of new compds. It is probable that the complete system changes in solvents, mol. polymerization and aggregation taking place. C. C. DAVIS

Methods of determining abrasion, with particular reference to the relation between road performances and laboratory tests. L. J. LAMBOURN. *Trans. Inst. Rubber Industry* 4, 210-34(1928); *Rubber Chemistry & Technology* 2, 166-92(1929).—The new type of abrasion machine, termed a "controllable slip" abrasion machine (cf. Brit. pat. 282,131), which is described and illustrated, has been so designed that rubber samples are abraded under controlled pressure intensity and slip, which may be regulated before or during the test to meet the conditions to be simulated. In this way the chief factors governing wear, viz., the nature of the surface, the intensity of pressure and the slippage, can be regulated so that each plays the correct relative part, resulting in a close approach to the particular conditions of road wear which it is desired to imitate. The results obtained with the app. indicate that it gives a correct forecast of road performance in 9 out of 10 cases. Expts. show that the work of abrasion is proportional to the magnitude of the slip, so that testing at const. slip is practically the same as testing under const. work. The new app. gives correct results over a greater range of hardness than any previous app. Various facts may be learned or confirmed by the app. Thus it was found that the rate of wear of a tire increased approx. with the square of the slippage, and where one mixt. was better than another at low % slippages, at higher % slippages the order of merit changed so that the mixt. which was inferior at low slippage became more resistant to abrasion when the slippage was high. A relatively hard mixt. is usually best when the speed and therefore the slippage is high, for it consumes less power and does not become so hot. Tests are also described to show the remarkably high rate of wear in summer, the very small wear when rubber is wet and the great effect which the character of the surface, the speed, the acceleration and the construction of an automobile have on the wear of tires. Various other subjects relating to abrasion and lab. and performance tests are discussed. C. C. D.

Measuring temperatures of calender rolls (KELTNER) 1. Negative catalysis in slow and induced reactions (DHAR) 2. Artificial leather (Austrian pat. 111,535) 29. Apparatus for circulating rubber dispersions, etc., to prevent separation of their constituents (Brit. pat. 293,072) 1. Use of rubber on a concrete foundation for road surfaces (Brit. pat. 292,681) 20. Determination of the temperature of high-speed bodies such as the rollers of rubber-making machines (Ger. pat. 470,201) 13. Objects from plastic substances such as rubber (Ger. pat. 470,270) 18.

Rubber latex. THE NAUGATUCK CHEMICAL CO. Fr. 643,122, Oct. 18, 1927. See Brit. 282,011 (C. A. 22, 3805).

Treating rubber latex. SOCIETÀ ITALIANA PIRELLI. Brit. 292,964, June 27, 1927. Latex is rendered coagulable by heat by addn. of oxides or hydrates of bi- and tervalent metals such as Zn, Mg, Al or Ca and a salt of NH_4 such as the sulfate. Salts of the same metals also may be added, and the treated latex may be used for the direct production of rubber articles. Cf. C. A. 22, 4877.

Deposition of rubber from latex. W. A. WILLIAMS. Brit. 293,095, March 28, 1927. In effecting deposition from material such as ammoniacal latex, there is added a salt of the metal employed as anode, e. g., $ZnSO_4$ when Zn electrodes are used. Various other details are described. Cf. C. A. 23, 547.

Rubber compositions. SIDNEY M. CADWELL (to Naugatuck Chemical Co.). U. S. 1,701,946, Feb. 12. Rubber is admixed with 2 or more of the ingredients: dibenzylamine, CS_2 or a material contg. CS_2 such as "oxy-*n*-butylthiocarbonic acid disulfide," (di-Bu ester of dithiobis [thionoformic acid]) Zn in combination such as ZnO and S, and then, substantially without change of form, the remainder of the vulcanizing ingredients are introduced from soln. The dibenzylamine and CS_2 are always separately introduced.

Coating composition containing rubber. CHARLES M. A. STINE and JAMES E. BOOGE (to E. I. du Pont de Nemours & Co.). U. S. 1,700,779, Feb. 5. In order to form a rubber-contg. coating on metals or other materials, a mixt. comprising rubber, a volatile thinner such as benzine and a Co, Mn, Pb, Zn or other suitable metal drier is applied to the surface and is exposed to the air and heated to cure the rubber by the action of the drier and evapn. of the thinner. Cf. C. A. 22, 1705.

Hard rubber coating composition. SAMUEL E. SHEPPARD and JOHN J. SCHMITT (to Eastman Kodak Co.). U. S. 1,701,129, Feb. 5. Commiunited hard rubber is digested in an aq. NaOH soln. for 2-5 hrs., the alkali is washed out and the treated material is dried and is incorporated with a molten flux comprising rosin and China wood oil and heated at 200-250° to produce a homogeneous fusion product; the latter is then dissolved in three times its quantity of a solvent such as benzene and coal tar naphtha to form a compn. suitable for spray-coating of metal.

Rubber articles reënforced with long fibrous material. WILLIAM B. WESCOTT (to Rubber Latex Research Corp.). U. S. 1,702,225, Feb. 12. In forming material for shoe soles or other articles, relatively long fibers such as cotton or ramie impregnated with latex rubber are distributed through a rubber compn. by milling.

Drying rubber articles. P. KLEIN (to Anode Rubber Co., Ltd.). Brit. 293,061, Jan. 25, 1927. Shaped articles of substantial thickness produced by immersing a former in an aq. dispersion of rubber or the like are dried by maintaining one side at a higher temp. and permitting escape of water from the other side on which an impervious skin is prevented from forming until the drying is completed. The articles may be dried on metal molds heated by elec. resistances or by induction. Various details and modifications of procedure are given and the process is applicable to cellulose esters, natural or synthetic resins, casein or albumin compns., etc.

Roughened or ornamental surface on rubber articles. S. D. SUTTON and VEEDIP, LTD. Brit. 293,111, March 30, 1927. A final coating of coned latex is partially dried, treated with a solvent, and then further dried. Various details and modifications are given.

Variegated markings on rubber surfaces. DUNLOP RUBBER CO., LTD. and G. G. THORNTON. Brit. 292,704, March 29, 1927. Irregular embossed markings are produced on surfaces such as rubber by deposition from aq. dispersions, by placing the articles between 2 surfaces such as metal and vulcanizing in boiling water or an aq. soln.

Rubber sheets with grain-like markings. C. MACINTOSH & Co., LTD., S. A. BRAZIER and G. F. THOMPSON. Brit. 292,754, May 26, 1927. Sheets of rubber are coated with a rubber soln. of different color, assembled into blocks (which may be deformed under pressure) and the blocks are sliced.

Artificial rubber. I. G. FARBENIND. A.-G. Brit. 292,103, June 13, 1927. Polymerization of di-olefins emulsified in suitable liquids (such as aq. emulsions which may contain proteids, milk, dextrin, soaps or sulfonates) is effected by the use of H₂O₂ with or without other polymerizing agents, buffer mixts., etc.

Molds (of aluminum or aluminum alloy) for molding rubber tires. H. A. BRITAIN (to Goodyear Tire & Rubber Co.). Brit. 292,905, June 25, 1927. Mech. features.

Rubber-masticating apparatus. PARK E. WELTON. U. S. 1,701,832, Feb. 12.

Waste rubber. THE DUNLOP RUBBER CO., LTD. Fr. 643,357, Nov. 4, 1927. Waste rubber is reduced to small pieces mixed with 1-3% of pure S and 1/2 to 3% of an antioxidant, the whole being vulcanized under pressure. As antioxidant, quinol, aminophenol, diaminophenol, aldol, naphthylamine or condensation products of aldehydes and aromatic amines may be used.

Refining reclaimed rubber. JOHN F. FISHER and WALLACE R. GILLAM (to Philadelphia Rubber Works Co.). U. S. 1,700,287, Jan. 29. The rubber is passed through a mill to form it into a continuous sheet, divided lengthwise into strips to sep. stocks of different grades contained in the sheet, and the stock of one grade is fed back into the mill substantially in constant ratio to the feeding of new stock into the mill. An app. is described.

Tennis balls. C. MACINTOSH & Co., LTD., S. A. BRAZIER and L. R. RIDGWAY. Brit. 293,124, April 1, 1927. A cloth-covered tennis ball is treated by immersion or otherwise with a rubber or gutta percha soln. and is afterwards vulcanized, preferably with use of an accelerator of the dithiocarbamate or xanthate class.

Accelerator for vulcanization. JAN TERPPEMA (to The Goodyear Tire and Rubber Co.). Can. 286,105, Jan. 1, 1929. Rubber is vulcanized by heating a mixt. contg. rubber, S and a reaction product of mercaptobenzoxazole and a basic N compd. contg. at least two hydrocarbon groups. Cf. C. A. 22, 2404.

CHEMICAL ABSTRACTS

Vol. 23.

APRIL 10, 1929

No. 7

-APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Continuous laboratory extractor for liquids. ALFRED W. FRANCIS. *Ind. Eng. Chem., Analytical Ed.* 1, 15(1929).—A simple, efficient app. that can be made in the lab. is described. J. H. MOORE

Contemporary tube still. A. M. TREGUBOV. *Azerbeidzyanskoye Neftyanoe Khozyaistvo* 1928, No. 6/7, 46-51, No. 10, 41-8.—Description and calcs. for a shell tube still battery are given. A. A. BOEHTLINGK

New investigation on the mode of operation of high-percentage distilling apparatus. E. LAIDNER AND W. KILP. *Chem. Fabrik* 1928, 713-5, 726-7.—Results are given on further expts. with 2 sets of app., each consisting of a masu column of 16 compartments and a rectifier of about 30 compartments. Cf. *C. A.* 22, 663. J. H. MOORE

Calculation of rectification columns. A. M. TREGUBOV. *Azerbeidzyanskoye Neftyanoe Khozyaistvo* 1928, No. 11, 25-37.—Very complete calculations on the above subject are given. A. A. BOEHTLINGK

Ultrafiltration. R. WASMUTH. *Chem. Fabrik* 1928, 405-6.—Among the advantages of the membrane filter is that adsorption effects, such as the staining brown of filter paper by Fe bromide soln. from the formation of basic salt, do not occur. Two methods of securing a membrane filter held between two filter papers and resting on a perforated porcelain plate are described. Another app. is designed for the treatment of steel turnings with Br soln. and the ultrafiltration of the insol. residue, with exclusion of air. B. C. A.

Apparatus for microfiltration. K. L. MALJAROV. *Mikrochem.* 6, 103-5(1928).—The app. comprises two pieces of thick-walled glass tubing, the lower end of the longer piece and the upper end of the shorter piece being thickened and ground flat so as to form a perfect joint between the two. The lower end of the shorter piece is drawn out to a capillary jet and the two pieces are held together with a bow-shaped spring clamp after a small piece of any type of filter paper is inserted between them. The filter is placed with the jet in the liquid; suction is applied by means of the mouth at the upper end. The filtrate collects above the paper and the collecting tube may, if desired, be provided with a small bulb to increase its capacity. B. C. A.

Method for detecting leaks in glass vacuum apparatus. P. SELENYI. *Z. Physik* 48, 733-4(1928).—The residual gas inside the vacuum app. is excited by a Tesla current while another gas leaks into the app. If the light emitted by the two gases is markedly different, as with CO₂ and air, the leaking spot can be detected directly by the change in color in its vicinity. B. C. A.

Adjustable needle-valve leaks. C. T. KNIPP. *Nature* 122, 131(1928).—Three forms of needle valve, one of which admits of calibration, and all being constructed with very long and narrow needles, are described and figured. B. C. A.

Automatic pipet. O. ORTH. *Chem. Fabrik* 1928, 492.—The pipet has a glass tap at the bottom and is expanded to a bulb at the top. The graduation mark is on the constriction below the bulb and a capillary filling tube ends on a level therewith. The pipet is filled from a wash bottle at a lower level and any surplus runs back. The filling and air release connections are either fused in or taken through a rubber stopper. B. C. A.

A precision valve for gases and liquids, particularly for burets to contain liquid and a description of a buret without stopcock. P. FUCHS. *Z. anal. Chem.* 76, 166-73 (1929).—A novel buret without stopcock is prepd. by drawing out the end of some glass tubing to a hook and fusing a glass bead to the outer part of the bend. Then when a short piece of rubber tubing is placed over the hook, the opening of the tube is pressed air-tight against the tubing. The other end of the tubing is connected tightly with the top of the buret and the whole tubing is about as long as the buret. The lower end of the buret is drawn out for about 10 cm. into a capillary of 1-1.5 mm. diam. By

pressing against the rubber at the valve, air can be made to enter the buret so that the liquid escapes. In this way all contact of the soln. with rubber or with stopcock grease is avoided and the buret can be made to deliver a single drop. Modifications of this valve are also shown at the bottom of a buret; in some cases the lower end of the buret is bent into a hook and in other cases the delivery tip is bent. W. T. H.

Some improvements in apparatus for gas analysis. H. A. BAHR. *Chem. Fabrik* 1929, 13-5.—A modified Czako absorption pipet is described; also an improved Orsat app. with which a complete analysis, including H and CH₄, can be made in 20 mins. with an accuracy of 0.1-0.2%. J. H. MOORE

Apparatus for storing and circulating gases. F. PETZOLD. *Chem. Fabrik* 1928, 716-7; cf. *C. A.* 22, 700. J. H. MOORE

Gas circulating pump. GUY BARR. *J. Chem. Soc.* 1928, 3293-5.—A pump for circulating gases within a closed system is described. It is an improvement on the device of Maass (*C. A.* 13, 273) in that economy of water is attained. A piston of Hg driven by water pressure and embodying its own valve system circulates the gas. Vols. of 100 cc. per min. against a head of 1 in. of H₂O can be circulated, the water consumption being approx. 100 cc. per min. Against higher heads the consumption is somewhat greater. C. Z. ROSECRANS

Gas pump for circulating various gases through a closed system. M. DOLCH AND K. GIESELER. Univ.-Inst. für tech. Chem., Halle. *Chem. App.* 15, 229-31, 268-9(1928).—The pump consists of Hg valves operated by a small motor through an arm to which are suspended the 2 leveling flasks. The rate of circulation has wide limits. J. H. MOORE

The Mawald rotary pump. KARL KLEMM. *Chem.-Ztg.* 52, 985-6(1928) A valveless pump which will pump at a suction of 9 m. and deliver at a pressure of 20 atm. It is especially adapted to handling benzine, NH₃ liquors, petroleum, lyes, curd soap, boiling oils, tar, etc. J. H. MOORE

Thomas recording gas calorimeter. ANON. Dept. Sci. Ind. Res., *Fuel Res., Tech. Paper* No. 20, 42 pp.(1928).—The results of expts. of a fundamental nature carried out on the earlier models indicate that (1) with gas of const. calorific value the record made by the calorimeter is correct within about 1%; (2) when the calorific value alters, there is a lag of about 30 min. before the change appears to its full extent on the record, small or temporary changes being ignored or under-estimated; over long periods the av. of the record agrees satisfactorily with values obtained on a Simmance machine; (3) variations of gas pressure, voltage of elec. supply, room temp. and barometric pressure, within reasonable limits, do not upset the performance. After these tests the instrument was altered in the heat-absorbing air meter where disturbance of the water level was lessened by changes in the construction of the vanes and of inlet and outlet ports, in the const.-level water feed where incoming water was made to splash on to the overflow weir, and in the burner which was constructed of silica instead of metal. Finally, changes were made in the recording mechanism by which it became more sensitive and less liable to lag and to irregular working. Tests on the modified app. indicate that (1) a steady reading can be obtained about 20 min. after lighting the burner, and if the calorific value of the gas is changed, this will appear within about 4 mins., but only to its full extent after about 15-20 mins.; at more frequent intervals than this, changes are not recorded to their proper value, although the periods and the av. will be correct; (2) fluctuations in the speed of the driving motor have small permanent disturbing effects, but may cause larger temporary errors; (3) changes in the level of the water in the tank must be avoided as far as possible, as a decrease of even 0.1 in. produces a rise of about 18 B. t. u. on the chart; (4) the recording mechanism is satisfactory, and no troubles were encountered in other mech. parts; the instrument is more accurate than water-flow or differential-expansion types, although its time lag is greater. B. C. A.

Portable electric stirrer. E. ZIEHL. *Chem. Fabrik* 1928, 729.—Similar to the "Hy-Speed." J. H. MOORE

Improvements in the apparatus of micro-Dumas. SHIGEO OKIDO. *Bull. Inst. Phys. Chem. Research* 8, 25-6(1929); *Abstracts* 2, 2.—The following improvements are applied to the microchemical N detn.: After preheating the combustion tube in a current of air, CO₂ is passed through the tube when it is still red hot and until it is completely cooled down, the purpose of this being to prevent air being trapped in CuO. A 3-way cock is inserted between the CO₂ generator and the bubble counter, which makes it very convenient to stop the CO₂ current at any time during the analysis. ALBERT L. HENNE

Device for carbon and hydrogen analysis of volatile, explosive and easily carbon-

izable organic liquids. MANASSEH G. SEVAG. Columbia Univ. *Ind. Eng. Chem., Analytical Ed.* 1, 16-7(1929).—This simple device consists of a small Pyrex tube contg. kieselguhr in which the liquid is absorbed, weighed and introduced into the combustion tube.

J. H. MOORE

Automatic apparatus for the determination of small concentrations of sulfur dioxide in air. II. MOYER D. THOMAS AND JOHN N. ABERSOLD. *Ind. Eng. Chem., Analytical Ed.* 1, 14-5(1929).—The app. previously described (*C. A.* 22, 2687) is slightly modified and an acidulated soln. of 0.006% H_2O_2 is used as the absorbent.

J. H. MOORE

Drying chamber for analytical and preparative work. F. HAHN. *Chem. Inst. d. Univ. Frankfurt. Chem.-Ztg.* 52, 975(1928).—The app. may be attached to the rod of a stand. The door is not hinged but hangs on a lip at the top of the chamber and remains closed by its own wt.

J. H. MOORE

Weighing systems as illustrated by modern scales. KARSTEN. *Chem. Fabrik* 1929, 3-5.—A description of modern (German) commercial varieties of platform scales, etc.

W. C. EBAUGH

Hartmann and Braun's spring balance. J. E. VERSCHAFFELT AND E. VAN DE CASTEELE. *Natuurwetensch. Tijds.* 10, 35-46(1928).—The balance is described, and the relation between load and reading under ordinary working conditions considered mathematically. The influence of temp. is important; it varies linearly with the load. A method of calibrating is described, and the effect of altering the adjustments examd.

B. C. A.

Weight buret. ISHIZO ITABASHI. Research Lab., Government Railway Office. *J. Paints, Pigments and Printing Ink* 2, 107(1928).—For weighing out such viscous liquids as varnish, an all-glass app., weighing about 40 g., consists of burets, a conical flask, which also serves as a receiver of the liquid, tube-like stopper and a lid. The capacity is 15 cc. The app. may be put on the pan of a chemical balance. Advantage is claimed in its ease of cleaning and in lessening the evapn. of volatile liquid.

K. S.

A pneumatic regulator for use with burets without stopcocks. EUGEN SHILOV. Polytech. Inst. Ivano-Woznessensk. *Z. anal. Chem.* 76, 212-6(1929).—S. has already described a buret without stopcock, which was worked by means of a levelling app. contg. liquid. In this paper several forms are described of a device which, in its simplest form, consists of an elastic sheet of rubber stretched over the edges of a glass plate. By movement of a screw, the elastic membrane is pushed outward, accomplishing air pressure on the liquid in the buret so that it flows out, or pulled inward so that the buret sucks up liquid.

W. T. H.

A new universal apparatus for microanalysis. I. Ashing in a closed system. ERNST TSCHOPP. Univ. Basel. *Biochem. Z.* 203, 267-77(1928).—Two types of the app. are described of which the more simplified model is shown in the figure. It consists of 2 parts: (1) the small flask in which the ashing takes place and (2) the condenser. The ashing mixt. (HNO_3 , H_2O_2 , etc.) is admitted from the cup *c*. The fumes rise through *r* and condense in the bulb *v*, from which the material can either be passed into *f* and thence into a receiving soln., or it may be transferred to *H* by the proper adjustment of the 3-way stopcock *d*. By turning stopcock 1 the substance can be readmitted to the flask. The oxidation is carried out by means of HNO_3 and H_2O_2 , but if Cl is to be detd., a measured amt. of $AgNO_3$ is also introduced into the flask. The soln. is transferred to a 25 cc. flask, made up to vol. with H_2O , and is used for detg. Cl, SO_4 , P, Na, K, Ca, Mg, Fe, etc. The Cl is detd. by titrating back the Ag in an aliquot of the soln. Five cc. of the filtered soln. is treated with 5 drops of fuming HNO_3 and 3 cc. of 2% starch and titrated with a standard 0.02 N KI to the first blue color. An alternative procedure is to allow the HCl formed in the acid ashing to pass through tube *f* into a flask contg. a measured amt. of $AgNO_3$. This is continued until no more turbidity is produced when the stopcock *d* is closed and the ashing with HNO_3 + H_2O_2 is started. In case the Cl was bound in the combustion flask with $AgNO_3$, it becomes necessary to get rid of Ag before proceeding with other analyses. This is accomplished by adding concd. HCl and filtering after 20 min. P can be detd. by any of the colorimetric methods depending upon the reduction of phosphomolybdate. The SO_4 is detd. by pptg. with $BaCl_2$ and weighing the ppt. of $BaSO_4$. For details of the procedure consult the test. Ca is detd. by the method of Kramer-Tisdall after previously adjusting the reaction. Mg is detd. in the filtrate from the CaC_2O_4 , the P being measured in the NH_4MgPO_4 ppt. colorimetrically. K is detd. by $KMnO_4$ titration (Kramer-Tisdall)

after the NH_3 is driven off by boiling with K-free NaOH . For the Na detn. the soln. is first treated with a little $\text{Bi}(\text{NO}_3)_3$ and Na-free K_2CO_3 to remove Fe and P, and the Na is pptd. as $6\text{NaNO}_3 \cdot 9\text{CsNO}_3 \cdot 5\text{Bi}(\text{NO}_3)_3$, which is detd. titrimetrically with 0.1 *N* KMnO_4 . The soln. can also be used for Fe analysis by the Fontès-Thivolle method (C. A. 18, 92).

A new apparatus for measuring hydrogen-ion concentrations. P. HANSON. *Dansk Tids. Farm.* 2, 139-40(1928).—The app. described is known as the Wulf's Foil-colorimeter. The working of this app. is based on the fact that the H- and OH-ions diffuse into a colloidal membrane much more rapidly than large mols., e. g., indicators diffuse out from such membranes into the surrounding liquid. If now a membrane contg. an indicator is placed in a soln. not to exceed 2 mins., its color will indicate the H-ion concn. of the soln. The app. is essentially a color scale obtained by mounting on parallel bars transparent strips impregnated with proper indicators and submerged in solns. of known p_{H} values. To make a p_{H} detn. a small strip contg. the proper indicator is submerged into the soln. to be tested for 2 mins., rinsed with distd. H_2O and dried between filter papers. It is then mounted on a slider which fits over the parallel bars (like a slider of a slide rule), and its color matched with one of the "standard" strips.

O. A. NELSON

Permeameter for testing magnet steel. B. J. BARBITT. *J. Optical Soc. Am.* 17, 47-58(1928).—The common com. permeameters are not capable of producing the high magnetizing forces required to det. accurately the magnetic properties of Co steel in bar form. The yoke type of permeameter may be adapted for this purpose by the use of extensions to the poles so that the distance between them is much less. In this way the greater part of the magnetomotive force is distributed over a short portion of the magnetic circuit and the force per cm. is correspondingly greater. The instrument described gives a very uniform magnetizing force directly proportional to the magnetizing current throughout a wide range of values. It is automatically compensated so that it records only ferric induction, is simple and rapid in operation, and possesses a high degree of accuracy.

B. C. A.

Sodium light for polarimetry. T. THUNBERG. *Svensk Farm. Tids.* 32, 569-70(1928).—An asbestos wick is soaked in NaCl soln. This is dried and gently ignited. A part of this is placed in the Bunsen flame when a polarimeter light is needed.

A. R. ROSE

Application of the vacuum tube in the falling-ball method for dark-colored solutions. E. M. SYMMES AND E. A. LANTZ. *Ind. Eng. Chem., Analytical Ed.* 1, 35-6(1929).—The falling-ball viscometer is used with translucent liquids but cannot be used where the ball cannot be seen. A vacuum tube, with suitable A and B supplies, has split grid and plate coils wound around the glass viscosity tube at definite distances apart. When the tube is oscillating at audio frequencies, the passage of the steel ball through the field of the coils causes a sharp change in the audible frequency.

E. M. SYMMES

Discharge tube with variable electrode distance. C. LEISS. *Z. Physik* 52, 750-1(1928).—The electrodes can be set accurately from the outside and the tube can be evacuated and fastened to a spectrograph.

GEORGE GLOCKLER

Something new in the continuous U. V. irradiation of liquids. A. KARSTEN-SALMONY. *Chem.-Ztg.* 52, 955-6(1928).—A description of Scholl's app. consisting of a quartz lamp and 3 water-cooled cells through which the liquid flows in parallel or in series, according to the degree of irradiation desired.

J. H. MOORE

A new large container. OSKAR KRON. *Chem. Fabrik* 1929, 15-6.—Rectangular tanks are made by bolting together plates of standard sizes.

J. H. MOORE

Tuboflex-Rotor pump. R. HEERWAGEN. *Apparatebau* 40, 302-3(1928)

J. H. MOORE

The condensate trap and its heat-technical significance. GUSTAV MANKENBERG. *Apparatebau* 40, 301-2(1928).—Cf. C. A. 22, 3808.

J. H. MOORE

Electrically heated thermocirculator for hot leaching and digesting. M. G. RAEDER. *Ind. Eng. Chem.* 21, 251-2(1929).—The app. consists of a glass bulb connected with a reflux condenser at the top and a circulation tube between the bottom and the upper part. The lower part of the tube is covered by a layer of asbestos sheet bound by a nichrome wire. This coil is insulated and protected on the outside by mica-mantled asbestos fastened with brass caps carrying contact screws and connected with an adjustable resistance. The characteristic feature of the app. is that the material to be leached is brought into vigorous circulation even when high in sp. gr. The form of the lift tube accentuates the pulsating motion. The circulation may be carried on for days without loss of liquid and without supervision. The app. should be well adapted for carrying out reactions between immiscible reactants at boiling temp.

W. H. B.

Supplement No. 6 to the results of the questionnaire to chemical factories on their experiences in the use of aluminum. ANON. *Apparatebau* 40, 274, 286-7, 296-7, 307-8(1928).—Cf. C. A. 22, 1500. J. H. MOORE

Cooling furnaces. ERICH ROUCKA. Ger. 470,327, May 30, 1926. The arrangement of the cooling pipes is described.

Laboratory centrifuge. MAX KIEL. Ger. 470,671, June 30, 1926.

Differential air thermometer compensated for barometric variations. SCIENTIFIC & PROJECTIONS, LTD., C. FAIRWEATHER, A. S. MARCH and G. L. WINDERS. Brit. 293,547, June 14, 1927.

Oil filter. MILLSON M. BASSETT (one-half to Lester I. Weil). U. S. 1,702,489, Feb. 19.

Sand filter (cleansed by agitation with reverse flow). W. PATERSON. Brit. 293,534, May 25, 1927. Structural features.

Filter for separating dust from air or other gases. CHARLES A. WINSLOW. U. S. 1,702,804, Feb. 19.

Dust separator. ÉMILE PRAT. Fr. 643,876, April 1, 1927. Dust is sepd. by a spiral ventilator stretching beyond 360° to continue the action of the centrifugal force on the dust, the gas at the periphery being diverted through a cyclone or other accessory app. in which the diverted gas is freed of its dust and may be returned at a point further on in the ventilator.

Apparatus for separating substances from gaseous mixtures by adsorption. VITALIS PANTENBURG. U. S. 1,702,311, Feb. 19. Material adsorbed at high pressure is released at lower pressure and the adsorbent recovered for further use.

Apparatus for separating oil from water, etc., by gravity and decantation. CARL K. MORSE (to Eleanor H. Morse). U. S. 1,702,612 and U. S. 1,702,613, Feb. 19.

Rough resilient surfaces for separating grains of different character. C. BUSSARD (to Soc. d'applications et de recherches scientifiques et industrielles (S. A. R. S. I.)). Brit. 293,389, July 5, 1927. Surfaces of rollers may be coated with a fine powder such as Pb_3O_4 or silica either embedded in the surface or applied in a flexible paint. Larger grains may be used in admixture with talc powder.

Apparatus for sorting friable material by gravity in a jet of air. V. E. TIR. Russ. 1532, Aug. 31, 1928. Friable material is continuously charged into the app. from a container with a baffle on the bottom and carried by a jet of air over different distances, dropped into containers placed in the chamber at various distances from the jet, whereby particles of diff. sizes are sepd.

High-speed beating apparatus for preparing fine dispersions of solids in liquids. W. H. WHATMOUGH. Brit. 293,510, April 29, 1927.

Röntgen-ray apparatus. E. POHL. Brit. 293,796, July 12, 1927.

Röntgen-ray apparatus. NAAMLOOZE VENNOOTSCHAP PHILIPS' GLOEILAMPEN-FABRIEKEN. Brit. 293,503, April 19, 1927.

Röntgen-ray tubes. E. G. GILSON (to British Thomson-Houston Co., Ltd.). Brit. 293,864, July 15, 1927. An anode is formed by surrounding one end of a metal supporting stem with refractory material and applying heat and pressure. The use of W. powder is described.

Röntgen-ray tubes. E. POHL. Brit. 293,318, July 2, 1927. Structural features.

Röntgen tubes with Lenard window. SIEMENS-REINIGER-VEIFA, GESELLSCHAFT FÜR MEDIZINISCHE TECHNIK M. B. H. Fr. 643,727 and 643,728, Nov. 10, 1927.

Electron discharge tubes. SOCIÉTÉ D'ÉLECTROCHIMIE, D'ÉLECTROMÉTALLURGIE ET DES ACIÉRIES ÉLECTRIQUES D'UGINE and RAUL BRUCKERT. Fr. 642,567, Oct. 19, 1927. An alkali or alk. earth metal is placed in the tubes so that the vapor tension of the metal produces an atm. favorable to the emissive power of the tube.

Electric discharge tubes. WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY. Fr. 643,977, Oct. 21, 1927.

Luminous electric discharge tubes suitable for flashing neon beacons. R. R. MACHLETT (to Rainbow Light, Inc.). Brit. 293,681, July 9, 1927. Structural features. Brit. 293,682 also relates to discharge tubes of the same general type. Brit. 293,683 relates to tubes of the glow-discharge type contg. an atm. of rarified A and Hg vapor (preferably evolved from small Hg mirrors distributed along the walls of the tube). The light from the tube is blue with clear glass and green with amber glass and the glow is uniform even at low temps. at which other tubes contg. Ne and Hg have a striated glow. Liberation of alkali metal from the glass, which might produce a striated glow, is prevented by using boro-silica glass and immersing the glass in 2% HF soln. or other

suitable acid for several days before use in making the tube. Various other details are described.

Cathodes for electrical discharge tubes. NAAMLÖÖZE VENNOOTSCHAP PHILIPS' GLOEILAMPENFABRIEKEN. Ger. 470,421, June 29, 1924. The cathodes comprise a core having a surface formed, at least in part, from an oxide of a metal, e. g., Cu, capable of forming alloys with alk. earth metals. A layer of alk. earth metal is applied to the core, which is then heated in a non-oxidizing atmosphere so that the alk. earth metal melts. Finally, the alk. earth metal is oxidized. The cathode may be heated again in a reducing atmosphere, e. g., of H or Mg vapor. The prepn. of a cathode *in situ* is described.

Cathode discharge tubes. SOCIÉTÉ ANON. RÉUNIE DE LAMPES À INCANDESCENCE ET D'ÉLECTRICITÉ. Fr. 644,097, Nov. 18, 1927.

Cathode discharge tubes. SOC. ANON. RÉUNIE DE LAMPES À INCANDESCENCE ET D'ÉLECTRICITÉ. Fr. 644,164, Nov. 19, 1927. A combination of a metal of high emissive power, such as alk. earth metals and Th, and a reducing agent such as finely powdered Mg are placed in the tubes and afterwards heated *in vacuo* so that the metal is first reduced, then vaporized and deposited on the core of the cathode.

Thermionic valves. S. LOEWE. Brit. 293,694, July 9, 1927. Electron-emitting materials such as metallic oxides, sulfides or carbonates are brought into sol. and, preferably, colloidal form and sprayed on a core in the form of minute drops. An app. is described in which a plurality of sprayers may be arranged around a wheel and the cathode may be heated in a reducing flame or in a neutral gas between successive spraying operations.

Vacuum electric tubes with thermionic cathodes. E. Y. ROBINSON and METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Brit. 293,723, March 11, 1927. When an indirectly heated cathode such as a Ni tube coated with Ba and Sr oxide and heated by radiation or conduction from a heater or by electron bombardment from an auxiliary cathode is used, the cathode is originally coated with carbonate and is heated by an elec. current to form the oxides after pumping the vacuum tube without heat-treating the electrodes and after sealing. Other details also are specified.

High-tension cables with passages for leading cooling fluid to and from x-ray tubes. NAAMLÖÖZE VENNOOTSCHAP PHILIPS' GLOEILAMPENFABRIEKEN. Brit. 293,731, April 11, 1927.

Quartz mercury-vapor lamp and associated apparatus for producing ultra-violet rays. F. W. ROBINSON and L. F. BIRD (to Hanovia Chemical & Mfg. Co.). Brit. 293,257, Aug. 24, 1927.

Catalyst tube. SOCIÉTÉ D'ÉLECTROCHIMIE, D'ÉLECTROMÉTALLURGIE ET DES ACIÉRIES ÉLECTRIQUES D'UGINE. Fr. 643,923, Apr. 16, 1927. A catalyst tube for synthesis under high pressure comprises 2 chambers inside a hollow cylinder, and capable of being traversed successively by the gas, both serving as catalyst chambers or one as a preliminary purification chamber. The chambers may be concentric and may be sepd. by a heating element such as an elec. spiral.

Apparatus for regulating electric heating. SIEMENS-SCHUCKERTWERKE A. G. Ger. 470,396, Dec. 9, 1925. App. is described of the kind in which the speed of rotation of a rotary interruptor varies with the temp.

Barrel-shaped combustion chamber for coal-dust furnaces. FRÄNKEL & VIEBAHN. Ger. 470,578, April 2, 1925.

Apparatus for blowing pulverized materials into shaft furnaces. PAUL HESKAMP. Ger. 470,541, Sept. 17, 1927. The tubes, nozzles, etc., are made of basic pig iron.

Discharging means for shaft furnaces. GUSTAV A. STRECKER. Ger. 470,621, Nov. 25, 1926. Constructional improvements are described in app. of the kind comprising a stepped platform reciprocating under the furnace outlet.

Bakery furnaces. ANDRÉ MINNE. Fr. 33,326, Dec. 17, 1926. Addn. to 617,549.

Furnace charger. ROGER M. ANDRÉ. Ger. 470,655, Jan. 5, 1926. Constructional improvements are described in app. of the kind in which a fuel container attached to the grate by a system of levers is automatically brought to its discharging position as the wt. of fuel on the grate falls.

Burner for liquid fuel. SOCIÉTÉ REBOURG ET DUPONT. Fr. 643,906, April 15, 1927.

Gas-burner construction. ERNEST K. ANDERSON and GEORGE A. SIMMONS. U. S. 1,702,625, Feb. 19.

Submerged flame burner. O. BRUNLER. Brit. 293,814, April 7, 1927. Water or steam is supplied to a burner (the construction of which is described) with the fuel mixt. to avoid excessive heating of parts of the burner.

Regenerative chamber kiln with vertical chambers. C. ORRO & Co., G.M.B.H. Ger. 466,752, Oct. 15, 1925.

Annular rotary hearth oven for effecting carbonization of material in thin layers. TROCHNUNGS-, VERSCHWELUNGS- UND VERGASUNGS-GES. Brit. 293,449, July 7, 1927. In an app. such as that described in Brit. 289,137 (C. A. 23, 698), charging and discharging are effected at a plurality of points so that the oven is divided into sections, each forming a complete charge-treating unit.

Apparatus for conditioning and humidifying air. G. D. HARRIS (to Industrial Dryer Corp.). Brit. 293,471, July 8, 1927. A thermostatic valve controls the supply of fresh cold water to the app.

Lixiviating apparatus. MAURICE JUNIEN. Fr. 643,883, April 13, 1927. A lixiviating and washing app., particularly for saccharified sawdust, comprises one or more vats widening towards the top and carried on 2 bearings. The vats may be turned about an axis placed between the 2 centers of gravity of the full and empty vats. A double perforated bottom carrying an appropriate filtering medium is in communication with a vacuum pump.

Emulsifying apparatus. GUY C. HURRELL. Fr. 643,808, Nov. 14, 1927. Liquids to be emulsified are forced under pressure past a piston carefully adjusted in a pump.

Extraction apparatus for wood, bark, fruit, etc. SOCIÉTÉ ANON. BUSS. Fr. 643,763, Nov. 10, 1927.

Apparatus for measuring the mechanical strength of asphalt, tar, pitch or similar materials. E. B. TENTZIOR. Russ. 4990, Mar. 31, 1928. A water-tight container is completely immersed in a heated water bath. A rod having on the upper end a pan for weights is inserted through a packing and its lower end rests against a plate of the material under test in the water-tight container. The degree of indentation is read on a scale on the upper part of the rod.

Apparatus for testing the transverse strength of concrete blocks, etc. ORREN H. HANSARD and DONALD D. MCGUIRE. U. S. 1,702,603, Feb. 19.

Apparatus for drying clay, chalk, etc. R. DE REYTERE. Brit. 293,765, July 11, 1927.

Continuous rotating vacuum drier. JEAN B. VERNAY. Fr. 33,327, Dec. 18, 1926. Addn. to 619,595.

Preventing access of air to acetylene generators. JACOB KNAPPICH. Ger. 469,949, Mar. 25, 1927. Addn. to 469,508. The app. of Ger. 469,508 (C. A. 23, 1023) is elaborated by providing means whereby the sludge-removing cock and the cover of the charging hopper are locked when the gas holder descends.

Gas washer with distributing disks mounted on a rotating shaft. I. G. FARBERIND. A G Brit 293,807, July 12, 1927. Structural features.

Checkerwork construction for heat accumulators or towers for washing and cooling gases. F. KRUPP A.-G. FRIEDRICH-ALFRED-HÜTTE and H. BANSSEN. Brit. 293,447, July 8, 1927.

Plant for production and recovery of carbon by incomplete combustion of gases. AMANDUS HEINRICH. U. S. 1,702,968, Feb. 19.

Apparatus for preparing carbon paper, color pastes, etc. HAROLD W. A. DIXON. U. S. 1,702,380, Feb. 19.

Receptacles for gasoline or similar liquids. RENE COURTIN. U. S. 1,702,631, Feb. 19. The outer wall of a receptacle or tank which may be used on aircraft exposed to gunfire is coated with porous rubber compn., blotting paper or other suitable porous material and then, by use of a mold, is coated with a thicker layer, applied in molten condition, consisting of glycerol, gelatinous material, a "binding substance" such as glucose or molasses and water; after this compn. has set it is further coated with a water-tight protective sheathing material in which wire mesh is embedded.

Thermostatic valve. G. G. ROYER. Brit. 293,930, May 3, 1927.

Thermostatically controlled electrically heated air humidifying system. G. D. HARRIS (to Industrial Dryer Corp.). Brit. 293,692, July 9, 1927.

2—GENERAL AND PHYSICAL CHEMISTRY

FREDERICK L. BROWNE

David Wesson. J. C. OLSEN. *Ind. Eng. Chem.* 21, 290-1(1929). A brief biography, with portrait. E. J. C.

The seventy-fifth birthday of Bernhard Lepsius. *Zwiss. Z. angew. Chem.* 42, 145-6(1929).—Brief biography with portrait. E. H.

Historical paper on chemistry in Russia. The chemists of Moscow from the be-

ginning of the 19th century. B. N. MENSHTUKIN. *Ann. inst. anal. phys.-chim.* (Leningrad) 4, 1-22(1928).

E. J. C.

A graphic method for solving simple stoichiometric problems. CHARLES H. STONE. *J. Chem. Education* 5, 1444(1928).—On a sheet of cross-section paper, ruled in tenths, choose a point in the lower left-hand corner as origin and through it draw two lines at right angles as axes. Find next the values concerned in the problem, e. g., 87 g. of MnO_2 will liberate 71 g. of Cl_2 from HCl . Locate the point 87-71 and from it draw a line to the origin. Any point on this line will mark the intersection of two perpendiculars, one drawn from a position on the ordinate representing a given value, and the other to a point on the abscissa representing the corresponding value of the answer.

W. C. EBAUGH

Nomography. IV. O. LIESCHE. *Chem. Fabr.* 1928, 450-1, 463-5; cf. C. A. 22, 4017.—Nomograms on 3 linear scales effect graphical addn. and subtraction, on logarithmic scales multiplication and division. The first can be used for the soln. of linear equations with 2 independent variables, as in the "indirect" analysis of a mixt. of Sb tri- and penta-sulfides. An example of the use of logarithmic scales is given by the detn. of the vol.-% of converted NH_3 in the Haber process, given the pressure, temp. and equil. const.

B. C. A.

Nomography. V. OTTO LIESCHE. *Chem. Fabrik.* 1928, 583-4, 595-7, 621-3, cf. preceding abstract.—Tables are given of transversals with two parallel vectors and an oblique inner vector. Arrangements of axes and intersecting straight lines are shown whereby computations can be made for problems like (a) Wheatstone bridge, where $u:v::w:s-w$; (b) bimol. reactions, where $t:h::e:1-e$; (c) gas equations, where $u = u:v::q:l$ or $PV = 0.08207 (t + 273.1)$; (d) radioelement disintegration, where $(0.4343t)/(-\log \delta) = \tau$ or $\delta = e^{-(t/\tau)}$; (e) monomol. reactions, where $t:h::-\log(1-e):0.30105$; and (f) reduction of a gas vol. to 0° and 760 mm., where $F = (0.3593p)/(273.1 + t)$. The necessary equations are developed and methods of constructing the corresponding figures fully described.

Osmosis of ternary liquids. III. Experimental part. F. A. H. SCHREINEMAKERS AND B. C. VAN BALEN WALTER. *Proc. Acad. Sci. Amsterdam* 31, 560-8(1928); see C. A. 22, 4041.

E. H.

Osmosis of ternary liquids. VII. General considerations. Congruent and incongruent osmosis; the membrane. F. A. H. SCHREINEMAKERS. *Verslag Akad. Wetenschappen Amsterdam* 39, 849-56(1928); cf. C. A. 23, 1035, and preceding abstract.—A continuation of previous papers.

B. J. C. VAN DER HOEVEN

Electromotive relations of artificial membranes consisting of surface areas selectively permeable to cations and areas selectively permeable to anions. RUDOLF HOBBER AND FRIEDRICH HOFFMANN. *Univ. Kiel. Arch. ges. Physiol.* (Pflüger's) 220, 558-64(1928).—By simultaneously distributing from two pipets rhodamine collodion and plain collodion upon the surface of Hg contained in a Petri dish membranes are produced with which selective permeability effects can be disclosed. The areas of the membrane composed of the rhodamine collodion exhibit permeabilities and membrane potentials which are quite the opposite of those possessed by the areas formed of plain collodion. Apparently the plasma membrane of *Valonia* is of this complex nature.

G. H. S.

The atomic weight of copper from the Lake Superior region and from Chile. THEODORE W. RICHARDS AND ARTHUR W. PHILLIPS. *Harvard Univ. J. Am. Chem. Soc.* 51, 400-10(1929).—No difference was found in the at. wts. of specimens of Cu from the Calumet and Hecla mines in the Lake Superior region in Michigan and from Chuquibambata, Chile. The ratio of the at. wt. of Cu to that of Ag was detd. by analysis of pure, recrystd. $CuCl_2$. The Cu was detd. electrolytically and the Cl by nephelometric titration with pure Ag. On the basis of Ag = 107.880, the at. wt. of Cu was found to be 63.557.

R. L. DODGE

The atomic weight of silver. O. HÖNIGSCHMID. *Z. Elektrochem.* 34, 625-7(1928).—At. wts. detd. by the analysis of halogen salts are based on the at. wt. of Ag as a secondary standard rather than on O = 16.000 as a primary standard. Although the analyses involved in such at. wt. detns. may have a precision of $1/10,000$, the precision of the at. wt. itself cannot be greater than that of Ag/O₂, estimated to be about $1/10,000$. For elements of high at. wt. this may lead to an uncertainty of several units in the second decimal place. Consequently, for several years past, the Munich at. wt. lab. has been engaged in the more precise detn. of Ag/O₂. The most recent method used is to convert a suitable perchlorate into chloride by heating in HCl gas, and then to analyze the chloride by means of Ag. All this is done on one sample. Ba(ClO₄)₂ has been used because it can be dried without decompn., and converted to the chloride at a temp. so low that loss does not occur. Several independent detns. by this method lead to the at. wt., Ag = 107.880, thus confirming the value adopted by the International At. Wt. Commission. Detn. of Ag/O₂ is also in progress based upon the analysis of Ag₂SO₄, combined with the synthesis and analysis of Ag₂S, thereby detg. the relations Ag₂SO₄/2Ag/Ag₂S. The ratio Ag/O₂ will thus be detd. without the aid of a second reference element. No exptl. details are given. R. H. LOMBARD

Chemical inertness of the rare gases. I. Action of helium on platinum. HORACIO DAMIANOVICH. *Anales soc. españ. fis. quim.* 26, 365-71(1928).—By means of an elec. discharge in a small tube, Pt was deposited in an atm. of spectroscopically pure He. Upon examn. of the deposit so obtained, it was found that the absorption of He, amounting to 14-34 cc. per g. Pt deposited, began with the appearance of the deposit of Pt. The deposit of He and Pt can be decompd. in a vacuum at temps. between 90° and 160°. When thus thermally decompd., the relation between the vol. of He evolved and the temp. resembles the decompn. relations of heterogeneous systems. An examn. by ultra-violet photomicrography indicated structural differences between the Pt-He deposit and the Pt obtained after thermal decompn. In explanation of the observations, it is proposed that the He is held in some state of combination with a part of the Pt. DON BROUSE

The fusion line of hydrogen up to 245 g. per sq. cm. W. VAN GULIK AND W. H. KEESOM. *Univ. Leiden. Verslag. Akad. Wetenschappen Amsterdam* 37, 888-9(1928).—The work of a previous publication (*C. A.* 21, 1387) was extended to higher pressures. From the results, in a table and graph, the following are selected: at 20.345° abs. pressure 245 kg. per sq. cm., at 19.69° 215, at 18.36° 161, at 17.27° 114, at 16.31° 97 kg. per sq. cm. pressure. B. J. C. VAN DER HOEVEN

Some physical constants of rhenium. IDA NODDACK. *Z. Elektrochem.* 34, 629-31(1928).—This is a brief survey of the phys. properties of Re. A spectrogram and table of wave lengths of the lines of the L-series of the Röntgen spectrum, as detd. by Beuthe, are given. The spark and arc spectra also are qual. well known, and several hundred lines in them are known certainly to belong to Re. The ultimate lines of the optical spectrum, especially the triplet at 3640 Å. U., serve to detect Re in concn. down to 10^{-7} , and greatly facilitate the examn. of Re-contg. minerals. The d. of the black metal powder formed by the reduction of ReS₂ in H₂ is 10.4. Re fused in the C-arc is white, similar in appearance to Pt, and stable in air. When melted on the anticathode, Re formed bright spheres 0.05 to 0.01 mm. diam., having a d. of about 20. The m. p. of Re is very high, possibly higher than that of W. There are indications that its b. p. is above that of W and C. Its sp. heat, 0° to 20°, is 0.0346. At. wts. have been detd. by analysis of Re₂O₃ and Re₂O₇, but the values are probably too high because of contamination by lower oxides. The most reliable figure for the at. wt. at present is 188.71 ± 0.25 , detd. by the reduction of ReS₂ to Re in a stream of H₂ at about 1000°. Details of this procedure are given. The analysis of ReCl₅ may furnish the best method for at. wt. detn. as soon as the properties and stability of the different Re chlorides have been studied more thoroughly. R. H. LOMBARD

The electric resistance of hafnium and zirconium between 1.3° and 90° absolute. W. J. DE HAAS AND J. VOOGD. *Univ. Leiden. Verslag. Akad. Wetenschappen Amsterdam* 37, 872-4(1928).—The sp. resistance of Hf at 0° is $0.0000296 \pm 2\%$. Measurements between 1.3° and 90° abs. show for both Hf and Zr a continuous drop of R/R_0 with T , with no indication of superconduction. Below 4.2° R/R_0 for Zr is practically const. at 0.0384, and for Hf at 0.0947. No min. (Koenigsberger and Schiller, *C. A.* 3, 141) was found for Zr. B. J. C. VAN DER HOEVEN

The platinum metals. S. C. OGBURN, JR. *Bucknell Univ. J. Chem. Education* 5, 1371-84(1928).—An address covering the history, occurrence, production, values, uses, properties, sepn. and analyses of the Pt metals. Outstanding features of the Pt metal situation recently have been (a) the development of Pt production in South

Africa, and (b) renewed activity of the Soviet government in establishing refineries and mfg. plants for working up Pt, as well as in mining the metal. To find atomic arrangements which will form stable and insol. substances with the Pt metals that may prove useful in sepg. them, 33 typical inorg. compds. and 90 organic compds. were tried on the 6 metals, [under varying exptl. conditions (cf. C. A. 20, 3663). It is concluded that (1) the most reactive classes of inorg. compds. acting with the formation of metallic ppts. are sulfides, thiosulfates, hydroxides, halides, certain reducing agents (N_2H_4 , NH_2OH and P), and some metals (Mg or Zn) more electropositive than Pt; (2) the most reactive types of org. compds. are alkaloïds, oximes, aromatic amines, non-substituted nitrosohydroxy compds., nitroso aromatic amines, pure hydroxy compds. and aminohydroxy compds.; (3) there is a marked difference in the ease with which these metals act toward both classes of reagents with the formation of insol. compds. and definitely colored solns., it being safe to assume that, with the exception of Ir, the nearer the Pt metal approaches its satn. value, in terms of electrons, in the next to the last electronic orbit, the more reactive is that metal toward the formation of coordinated salts; (4) new color reactions for certain metals (in the absence of others) are (a) Ru—deep violet on boiling with phloroglucinol after the Ru soln. has been made alk. with KNO_3 , and a deep violet soln. on warming with *p*-nitrosophenol; (b) Os—deep rose soln. on warming K osmate with aniline sulfate and a violet soln. with K chlorosmate; a deep blue soln. with β -naphthylamine hydrochloride, pyrocatechol and pyrogallol; (c) Ir—a deep blue soln. on warming with aniline sulfate; (d) Pt—a blood-red soln., changing to brownish red, on boiling with pyrocatechol or pyrogallol, and the same color with resorcinol, if the soln. be made ammoniacal. A short gravimetric scheme for the *sepn. of the Pt metals* is presented, with the claim that an accuracy of 1.5% for each of the metals is obtainable.

W. C. EBAUGH

The sublimation of sulfur between 25° and 50°. ROY P. TUCKER. Calif. State Dept. Agr. *Ind. Eng. Chem.* 21, 44-7(1929).—To det. the relative values of different kinds of S when used to control plant diseases an investigation of ground S, sublimed S and gas-purification S was conducted. Irrespective of its form S sublims at 25-50°, the comparative rates of sublimation at 24-26°, 30-35° and 40-45° were found to be in the ratio of 1:6:80. If mixed with lampblack and exposed to sunlight, temps of the mixts. were 5-10° higher than those of control samples of pure S, thus indicating a method for increasing the quantity of S sublimed. Observations upon (a) area shrinkage of S particles, as detd. by the microscope, and (b) the rate of blackening of Ag foil test pieces exposed to the action of equal wts. of various forms of S and S-mixts., spread over equal areas, showed that the size of particle, moisture and light are without influence upon the sublimation rate, but that heat is the detg. factor. By weighing tests, the Ag-foil test and microscopic study it was learned that there was no material difference in the sublimation rates of the three kinds of S. While the tests were not conclusive it was indicated that S loses its power of sublimation to a considerable extent at 35° and less when in contact with air.

W. C. EBAUGH

The broader aspect of valence: its application to colloid compounds. VICTOR COFMAN. E. I. Du Pont de Nemours & Co. *Chem Reviews* 5, 603-17(1928).—The classical idea of valence was developed to explain the properties of "pure" chem. compds. It is based on the law of const. proportions. In order to apply it to colloids, it will have to part completely from that law, since in colloids the proportions are far from const.

ALBERT L. HENNE

The theory of partial polarity of the ethylene bond and the existence of electroisomerism. M. S. KHARASCH AND F. R. DARKIS. Univ. of Maryland. *Chem Reviews* 5, 571-602(1928).—The various electronic hypotheses that have been advanced to interpret the directed addn. reaction of ethylene derivatives are compared. It is shown that the hypothesis of partial polarity of the double bond (Heinrich: Theories of Org. Chemistry) explains the facts more satisfactorily than any other. Exptl. data recorded for 35 ethylene addn. reactions are in conformity with the theory.

ALBERT L. HENNE

The interference of characteristic vibrations as the cause of energy fluctuations and chemical change. M. POLANYI AND E. WIGNER. *Z. physik. Chem., Abt. A*, 139, 439-52(1928).—Polanyi and Wigner attempt to explain the fact that the velocity const. of monomol. reactions contains, besides an exponential factor, a quantity of the order of magnitude of 10^{14} . They assume that the energy in a mol. vibrates in elastic waves surrounding the at. in the mol. The rupture of a bond in the mol. occurs through interference of waves whose amplitudes have risen above a certain critical value. This leads to the expression $\nu e^{-Q/RT}$ for the velocity const.,

where ν is the frequency of the vibrations and has therefore the right order of magnitude.

J. B. AUSTIN

The inverse process to spontaneous quantum shifts without radiation (inelastic collisions without radiation). ADOLF SMEKAL. *Ann. Physik* 87, 959-64(1928).—In the old quantum mechanics elastic collisions between two bodies without radiation could be pictured only by supposing that the resultant single body could absorb the quantum due to collision. The wave mechanics gives a finite probability of this absorption for every collision.

F. R. BICHOWSKY

Intermediate products of the combustion of methane. E. H. RIESENFELD AND D. GURIAN. Univ. Berlin. *Z. physik. Chem.*, Abt. A, 139, 169-97(1928).—Among the intermediate products of the burning of CH_4 and O_2 in a microflame, CH_2O , H_2O_2 and O_3 have been identified. The max. amt. of CH_2O is formed in the O_2 -flame (O_2 burning in CH_4) when the amt. of excess CH_4 is the largest and the cooling is greatest. The max. amt. of H_2O_2 is formed at the equiv. ratio of CH_4/O_2 and by the greatest cooling. On the other hand, the max O_3 yield is obtained in the CH_4 flame when the excess O_2 is the greatest and only a slight cooling is used. These facts indicate that H_2O_2 is not formed by oxidation of CH_2O but that the 2 are independent of each other. The formation of O_3 , however, is a result of the action of the at. O from the decompn. of H_2O_2 on mol. O_2 . The reactions that take place in the burning of CH_4 are concluded to be: (1) the primary reaction, decompn. of CH_4 into CH_2 and at. H and (2) the secondary reactions, (a) the formation and burning of CH_2O from CH_2 , or the simultaneous oxidation of CH_2 into CO and CO_2 , (b) the formation of H_2O_2 from at. H and O_2 , the decompn. of H_2O_2 into H_2O and at. O and the formation of O_3 by the combination of the latter with O_2 . A large part of the at. H forms H_2 which burns with the O_2 to form H_2O . The flame reactions were independent of the material from which the microburner was constructed. When equiv. amts. of the gases were burned under the same conditions the O_2 flame was more than twice as long as the CH_4 flame. The latter, however, was the hotter of the two.

H. F. JOHNSTONE

Optical properties of arsenic. II. F. GRYSZKIEWICZ-TROCHIMOWSKI AND S. F. SIKORSKI. *Roczniki Chem.* 8, 405-21; French, 421-2(1928); cf. C. A. 22, 1529.—The mol. refraction of 26 org. compds. of As was detd. The refraction no. was found to increase in the order $\text{CN} < \text{F} < \text{Cl} < \text{Br} < \text{I}$. Alkyl groups, Cl, H exert about the same influence on the at. refraction of trivalent As. A decrease of at. refraction was observed on replacing the alkyl groups, Cl and H, by methoxyl and ethoxyl groups.

J. KUČERA

A tabulation of the 32 crystal classes. AUSTIN F. ROGERS. *Am. Mineral.* 13, 571-7(1928).—In this tabulation there are 7 vertical columns which give in order, the crystal system, the no. of the class, the name of the class, the no. of faces in the general form of the class, a prominent example of the class and the symbols used by Schoenflies. There are 6 systems, the hexagonal being divided into 2 subsystems. The trigonal dipyramidal and ditrigonal dipyramidal classes belong to the hexagonal subsystem as proved by the theory of groups, and by the fact that they have as their space lattice a hexagonal prism only. Each of the 32 classes constitutes a mathematical group with its subgroups. Their names are adjectives, mostly derived from the name of the general form. An analytical study of the crystal symmetry with the aid of the theory of groups establishes definitely just what constitutes the symmetry operations and symmetry elements of crystals.

A. M. BRANT

Formation of Neumann bands. I. Mechanism of twinning in the body-centered cubic lattice. S. W. J. SMITH, A. A. DEE AND J. YOUNG. *Proc. Roy. Soc. (London)* A121, 477-86(1928).—The mirror image relation between twin crystals of the body-centered cubic lattice is believed to result from one of several different atomic movements with respect to the twin plane whereby the atoms reach a stable configuration as a result of some large or small distortion in the neighborhood of the twin plane. The atoms are assumed to move under impulsive stresses in the matrix in circular arcs or in lines parallel to the trigonal axis, and by diagrams it is shown how this may occur. The mid-way position of the twinning movement is one of unstable equil. and upon the force of the impulse depends whether the interatomic forces will restore the original orientation or accomplish the passage to the twin position in the matrix. The magnitude of the force may also det. the type of twinning. II. Evidence that the bands are twins. *Ibid* 486-500.—The test for the twin relationship between the orientation in a band and that in the matrix is to make a section of the material perpendicular to the plane to which the band is parallel and compare the pits produced by the same etchant on band and matrix. The authors have derived and drawn the geometric relations to be expected between the pits in the band and in the matrix in planes $\{111\}$,

{110}, {221}, {112} and {100}. Photomicrographs of etched surfaces of the respective crystallographic faces of a section of the Coahuila meteorite show pits corresponding very closely to the theoretical pits. III. Movement from which twinning results. *Ibid* 501-14.—The manner in which displacements are transmitted through the matrix and across bands already existing is illustrated by geometric diagrams and corresponding photomicrographs of the actual results of cross twinning. The calcd. relation between the displacement and the breadth of the band is in very close agreement with the exptl. ratio.

H. W. WALKER

The optical detection of porous regions in the molecular structure of crystal masses. ADOLF SMEKAL. *Anz. Akad. Wiss. Wien* 63, 195-7(1926).—The existence of "lattice pores" or other "deviations from ideal lattice structure" inferred from other properties of actual crystals (cf. C. A. 20, 683) is confirmed by optical data. The existence of internal photoelec. sensitivity exclusively for λ larger than the resonance λ of the lattice structural units of these crystals shows that in the crystal mass mol. units, even if only in small number, must be present, the outer electrons of which are more loosely held than those of the normal lattice structural units. Where the absorption spectrum of the lattice unit is known, direct comparison will show by what less voltage the crystal units not participating in the ideal lattice structure will be ionized than the normal lattice elements. The voltage difference in the case of heteropolar crystals photoelectrically sensitive in the visible region is 1.5-3.0 v. Those regions in the mol. structure of actual crystals in which this loosening of electronic forces exists are to be called "porous regions" (Lockerstellen). In the case of the alkali halides the phenomena of internal photoelec. sensitivity, coloration by quartz ultra-violet, and phosphorescence (Lenard's phosphors), and in the case of Ag halides the non-uniform deposition of Ag under illumination may be suitably correlated to each other and to the existence of porous regions, such mols. with looser outer electrons constituting but 10^{-3} to 10^{-4} of the total.

A. P. S.

Observations on the x-ray structure of the C—C bond. A. REIS AND W. SCHNEIDER. *Tech. Hochschule, Karlsruhe. Z. physik. Chem., Abt. A*, 137, 126-30(1928); cf. C. A. 20, 3104.—Since the earlier publication contg. speculations on the structure of compds. contg. a central C—C group, considerable information on the x-ray structure of such compds. has been obtained which is summarized in tables showing the relation of the different space groups and mol. symmetries. The symmetry characteristics of the mol. can be derived from the x-ray data uniquely in many cases, and in other cases with but few alternatives. The following conclusions are drawn from a survey of the tables. Mol. structure with central symmetry has been found with single as well as with double-bonded C atoms. A plane of symmetry has in no case been observed passing through the C—C bond. A 2-fold axis of rotation through the C—C bond may occur with the active form of the tartaric acid type as well as with compds. without stable isomers. In isomers or in modifications which have the same structural formulas, the occurrence of 2 kinds of 2-fold mol. symmetry has not yet been found. Symmetry elements parallel to the C—C bond have not been proved (except the 3-fold rotation axis of C_2H_6). In the crystal classes C_2 and V there have been found up to now only the space groups C_2^2 and V^4 in which unsymmetrical mols. are arranged on a screw axis. Enantiomorphic crystals of mols. C_2 belong to the trapezoidal classes D_2 or D_4 . Conversely in these classes D_2 and D_4 only those space groups have been found which are built up of mols. having the symmetry C_2 . The Weissenberg theory of crystal structure has been completely substantiated in all the cases investigated.

A. W. KENNEY

The symmetry and structure of cubical nitrates of calcium, strontium, barium and lead. F. M. JAEGER AND F. A. VAN MELLE. *Univ. Groningen. Verslag Akad. Wetenschappen Amsterdam* 37, 528-32; *Proc. Akad. Wetenschappen Amsterdam* 31, 651-5(1928).—Crystallographic evidence points to a tetrahedric pentagon dodecahedric symmetry for the Ca, Sr, Ba and Pb nitrates. However, circular polarization was never found. X-ray work indicated dyakisdodecahedric symmetry (T_h^d). Rotational spectrograms were made of an apparent cubo-octahedron of $Sr(NO_3)_2$ with $[1\bar{1}0]$ and $[100]$ as rotation axes; (210) and $(0\bar{2}1)$ were found present, not (100) , $(00\bar{3})$, (005) or (007) . A simple cubical lattice with $a_0 = 7.80$ A. U. and 4 mols. per unit cell is therefrom deduced. For $Ba(NO_3)_2$ was found $a_0 = 8.10$ A. U., 4 mols. per cell, space group T_4 . Likewise for $Pb(NO_3)_2$ the results indicated T_4 with $a_0 = 7.80$ to 7.81 A. U. ≈ 0.02 (Vegard gave 7.84). The symmetry of all 4 salts is therefore established as tetrahedric pentagon dodecahedric with metal atoms in uuu ; $(u + \frac{1}{2})$, $(\frac{1}{2} - u)$, \bar{u} ; \bar{u} , $(u + \frac{1}{2})$, $(\frac{1}{2} - u)$; $(\frac{1}{2} - u)$, \bar{u} , $(u + \frac{1}{2})$ on a 3-fold axis of sym-

metry; μ is almost zero. The N atoms have 2 similar 4-fold positions with 2 other values for μ , one positive, one negative and almost equal in abs. value; the O atoms take two 12-fold positions around the 3-fold axis with 3 parameters. This structure approaches the dyakisidodecahedral structure closely but is basically different. Only for the Ca salt can the N and O location be measured. Further examn. of the optical rotation, and pyro- or piezo-electricity is in progress. B. J. C. VAN DER HOEVEN

The crystal structure of some rhombic formates. ISAMU NITTA. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) 9, 151-63(1928).—By the Laue photographic and ionization spectrometric methods the crystal structure of some formates which belong to the orthorhombic system were investigated. The dimensions of the unit of structure, the no. of chem. mols. contd. in it, the corresponding space group and the calcd. d. are tabulated as follows:

Chemical formula	Unit of structure			No. of mols.	Space group	Density
	a	b	c			
Li(HCO ₂).H ₂ O	6.49	10.01	4.85	4	C _{2v} ⁹ or V _h ¹⁶	1.46
Ca(HCO ₂) ₂	10.16	13.38	6.26	8	V _h ¹⁵	2.02
Sr(HCO ₂) ₂	6.86	8.72	7.24	4	V ⁴	2.71
Sr(HCO ₂) ₂ .2H ₂ O	7.30	11.99	7.13	4	V ⁴	2.26
Ba(HCO ₂) ₂	6.78	8.89	7.68	4	V ⁴	3.24
Pb(HCO ₂) ₂	6.52	8.75	7.41	4	V ⁴	4.64

The described isomorphism among the formates of Sr, Ba and Pb was confirmed by the present x-ray investigation. The space group V_h¹⁵ for Ca formate is different from V_h¹⁵ assigned by K. Yardley. The former V_h¹⁵ contains V⁴ as a subgroup. The mols. of the formates of these bivalent metals are all structurally asymmetric. Discussion of the structure of these salts is also made from the view point of the morphotropic relation to the fluorides and nitrates of Sr, Ba and Pb. G. L. CLARK

Metallic fibers. RUDOLF SCHENCK, ROBERT FRICKE AND GEORG BRINKMANN. *Münster. Z. Physik. Chem., Abt. A*, 139, 32-46(1928).—The formation of "hair crystals" of Ag or Cu by heating a mixt. of the metal and its sulfide is probably due to a thermoelec. effect caused by an unequal distribution of heat. An x-ray examn. of the artificially produced and naturally occurring Ag and Cu fibers was made. For the Ag crystals the fiber axis was uniformly parallel to the [112] plane. The Laue diagram, however, was completely changed if the crystal had been tempered at 900°. It was for this reason, or because of their age, that the crystals of natural hair Ag did not show a uniform orientation. The crystals of hair Cu showed no regularity in the direction of their axes. For the greater part the axes were parallel to the planes [112] and [122]. The tempered crystals, however, were reoriented and their axes, like those of the natural crystals, were parallel to the [110] plane. For comparison with these results, an x-ray examn. of the hair crystals of NaCl, another face-centered cubic, was made. The fiber axes in this case were parallel to the [110] plane. H. F. J.

Proof of the adiabatic principle. M. BORN AND V. FOCK. *Z. Physik* 51, 165-80 (1928). Earlier proofs of the adiabatic principle that the quantized angle variable is const. for adiabatic changes of state are improved to cover degenerate but fully quantized single systems. Matrix methods are used. F. R. BICHOWSKY

The reversal point of second order (determination of the T₀ value). WITOLD JAZYNA. *Z. Physik* 51, 292-307(1928); cf. *C. A.* 22, 3816.—T₀ is calcd. from the fact that the H₂ and air thermometer scale converge on T₀. The method places T₀ between 272.9 and 273.1. F. R. BICHOWSKY

Properties of substances and mixtures at the absolute zero of temperature connected with change of state. R. D. KLEMAN. *J. Phys. Chem.* 32, 1841-55(1928); cf. *C. A.* 23, 1324.—The following are discussed: properties of the heat and external work of vapn. at 0° abs.; the properties of the condensed state at 0° abs.; the temp. coeff. of the pressure of the satd. vapor of a substance or mixt. at T = 0; the equation of state of the vapor of a substance near 0° abs.; the properties of the heat and work of mixing of substances in the gaseous state at 0° abs.; properties of the change in free energy and the heat of formation of substances in the gaseous state at 0° abs.; properties of the internal sp. heat of a vapor in contact with the condensed state; the heat of formation of mols. in the gaseous state at infinite vol. at a finite temp. It is shown that the temp. of a substance cannot be reduced to zero abs. in a finite time and that the controllable entropy of a substance is positive and can be infinite only when the temp. is infinite. E. G. VANDEN BOSCH

Relation between the absolute temperature and the mean kinetic energy of a gas molecule. KAMEKICHI SHIBA. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 576-9 (1928); *Abstracts* 1, 54.—The discordance between thermodynamics and the kinetic theory of gases is interpreted (*C. A.* 23, 1323-4). The second law of thermodynamics requires the mean kinetic energy $\bar{\epsilon}$ of a mol. with cohesion to depend upon the density. A first approximation calcn. shows for sufficiently high temps. and not too condensed states: $\bar{\epsilon} = \frac{3}{2}kT + (n-4)(A/NV)$, if V is the vol. of the gas, N is the total no. of gas mols. and A is a const.; the law of mol. attraction is supposed to be \bar{x}/r^n . A necessary consequence of the value of $\bar{\epsilon}$ is that the law of equipartition of energy is not generally applicable. Thus the discordance is reduced to that between the second law of thermodynamics and the law of equipartition of energy. *Conclusion.*—In such a case, the law of equipartition of energy is to be given up. ALBERT L. HENNE

Relation between surface energy of liquids and saturation vapor tension. N. BARBULESCU. *Univ. Cluj. Bull. soc. stiinte Cluj* 4, 251-62(1928).—On the ground that the surface energy of liquids is proportional to the heat of vaporization, a relation was sought between the surface energy and the vapor tension. For normal liquids the relation is $\alpha V^{2/3} = KT \log(\pi_0/p)$, where $\alpha V^{2/3}$ = surface energy, π_0 = crit. pressure. For associated liquids, the Nernst formula for the heat of vaporization was used; the formula finally arrived at was: $\alpha V^{2/3} = (A + BT + CT^2)(1 - [p/\pi_0])$. These formulas were verified for C_6H_6 , CCl_4 , $PhCl$, methyl formate, $EtOH$, $MeOH$ and $AcOH$ by using the Bogdan method of calcg. surface energy. ALBERT L. HENNE

Density and temperature. VII. W. HERZ. *Univ. Breslau. Z. Elektrochem.* 34, 857-8(1928); cf. *C. A.* 21, 3505.—At a temp. θ such that $\theta = \frac{1}{10} T_{cr}$ (T_{cr} = critical temp.), the ratio of the d. of the liquid to the d. of the vapor is about 10. At a temp. $\theta' = \frac{1}{3} T_{cr}$, which is generally close to the b. p., the ratio is much larger and is no longer const. The order of the 38 compds. considered changes when the ratios are calcd. for a different reduced temp. ALBERT L. HENNE

The leakage of helium through Pyrex glass at room temperature. GREGORY P. BAXTER, H. W. STARKWEATHER AND R. B. ELLESTAD. *Harvard Univ. Science* 68, 516-7(1928); cf. *C. A.* 21, 1728.—Leakage of He through Pyrex at 0° and atm. pressure was noted in 24 hrs. in change of PV with P expts. Mech. leakage was eliminated by comparative expts. with He at 770 mm., and at 627 mm. showing a like change per day in either case of about 0.0031%, corresponding to 0.04 cu. mm.³ per day per sq. cm.² The app. had previously showed no similar effect with A. These results were confirmed by comparing a spherical Pyrex globe filled with He with a counterpoise of a larger globe contg. A for a year. The loss in wt. per day gradually fell off; 0.02 mg. the 1st day; 0.007 the 18th; 0.006 the 34th, and decreased gradually from 0.0059 to 0.0047 from the 71st to the 366th. The total loss was 1.73 mg. He (1%) corresponding to an av. of 0.059 cu. mm.³ per day per sq. cm.² of Pyrex averaging 1.34 mm. in thickness. The detns. by B. and S. of the d. of He (*C. A.* 19, 1643; 20, 1006) carried out in Pyrex are not affected. The leakage expt. is being continued.

ALBERT THOMAS FELLOWS

Hydrodynamics and the kinetic theory of gases. Corrections to a previous work. Y. ROCARD. *Ann. phys.* 10, 345-8(1928).—Corrections and modifications are given for equations in a previous article (*C. A.* 21, 3779).

R. H. LOMBARD

Constant-boiling mixture of hydrogen fluoride and water. C. W. MUEHLBERGER. *Univ. of Wisconsin. J. Phys. Chem.* 32, 1888-9(1928).—Distn. of pure aq. HF in a Pt app. indicates that the const.-boiling mixt. is 38.18% HF ($\approx 0.10\%$) at a pressure of 735 mm. of Hg. The d. of this concn. of acid is 1.138 g./cc. at 20° . The b. p. of the mixt. detd. in a Pb app. is 110.8° at 732 mm.

E. G. VANDEN BOSCHE

Viscosity relationship in the system; sulfuric acid-nitric acid-water. F. H. RHODES AND H. B. HODGE, JR. *Ind. Eng. Chem.* 21, 142-50(1929).—The viscosities of a large no. of binary and ternary mixts. of these substances were detd. at 0° , 25° , 50° and 75° , showing the existence, in liquid form at ordinary temp., of $H_2SO_4 \cdot H_2O$ and a ternary compd. contg. SO_3 and N_2O_5 in the ratio $10SO_3 : N_2O_5$. There is no definite evidence of the existence of a liquid HNO_3 hydrate.

E. M. SYMMES

Solidification point and viscosity. A. BAADER AND H. GRUBER. *Archiv Eisenhüttenwesen* 1, 653-4(1928).—The app. described was used successfully for detg. viscosities of oils at low temps. Through the cover of a double-walled glass vessel (Dewar) the oil is introduced, contd. in another small glass vessel into which the lower end of a pipet is passed. The first vessel is filled (by means of a separatory funnel) with Et_2O to a few cm. over the bulb of the pipet. The oil is sucked into this to the correct height. Through a tube, leading to the bottom of the large container and provided with a porous plate, dried air is sprayed into the Et_2O and drawn out through another tube in the

cover with a H_2O pump. The viscosities are detd. as usual. The desired temp. is obtained by regulating the flow of air with the pump. By replacing the Et_2O with properly heated H_2O or any other suitable liquid, higher temps. may be obtained. Estg. the fluidity of oils by solidification point detns. is exptly. shown to be inaccurate. With the app. described the viscosities may be detd. at the temps. desired and plotted, the curve being characteristic for the oil.

J. BALOZIAN

The use of internal pressure in metallic systems. The system lead-antimony-copper. RALPH A. MORGEN. *Science* 68, 490-1; cf. *C. A.* 22, 903.—The shape of *miscibility gaps* may be predicted from the assumption that liquids with like internal pressures are more easily miscible than those with unlike. The m. p. and heat of fusion of the metal are also useful. The effect of compd. formation may be even greater, depending upon the stability of the compd. It is treated as a new component with its own properties when it is stable in the liquid phase, but has little effect on the miscibility of the liquid phase if the compd. dissociates before it melts, since then the liquid phase is composed of only the two original atoms. The shape of the liquidus and solidus surfaces depends on these principles and considered with the freezing curves the surfaces may be found. This method is applied to the Pb-Sb-Cu system and the generalization derived that the liquid behaves like a pure solvent or approaches a perfect soln. of the 2 constituents over the range where a solid soln. seps.

Physical constants of pure carbon-free chromium-iron and vanadium-iron alloys. K. RUF. Heraeus-Vacuum-Schmelze A.-G., Hanau. *Z. Elektrochem.* 34, 813-8 (1928). Many Cr-Fe and V-Fe test pieces with varying amts. of the components were prepd. The influence of compn. on sp. resistivity and its temp. coeff., thermoelectric force, sp. weight and thermic expansion coeff. is shown graphically.

ALBERT L. HENNE

Contact resistances. R. HOLM. *Z. tech. Physik* 9, 454-7 (1928).—The theory of H. (*C. A.* 21, 2216) is further elaborated. The influence of temp. on a typical "sieve" contact resistance is $R_t = R_0 (1 + \frac{2}{3} \alpha t)$ where α is the temp. coeff. of sp. resistance. From the Kohlrausch method relating thermal and elec. cond. the relation is deduced: $t + (\alpha/2)t^2 = 1/s(\lambda/k)V^2$, where λ and k are, resp., elec. and thermal cond. at room temp., and V is contact potential. The relation between R_t and V or t , resp., is shown graphically. With rising temp. R_t first follows the expected curve until recrystn. of the contact surface causes it to drop steeply. Pressure increase makes R drop in inverse proportion, independently of the size of the apparent contact surface. It is here assumed that the no. of isolated "a" surfaces of actual contact is proportional to the pressure. In several curves characteristics of metal contacts (Ni, Ag, Au, graphite) are demonstrated.

B. J. C. VAN DER HOEVEN

Dielectrics at high voltage. II. Impregnating oils. Insulating properties of some high-tension cables. SHOJI SETOH AND AKIRA MIYATA. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 581-634 (1928); *Abstracts* 1, 55-7.—Measurements are made of a. c. and d. c. characteristics of cylinder oil, petrolatum, castor oil, transformer oil, rosin oil, paraffin and vaseline. Influence of time of application of voltage and heat (up to 7 hours), intensity (up to 100 kv./cm.), and frequency (30 to 90 cycles) were studied at 20°, 40°, 60° and 80°. *Effect of time.*—In most cases a. c. losses increase, while d. c. losses decrease asymptotically with time; at 80° the d. c. losses of castor oil, paraffin and vaseline tend to increase continuously. A. c. losses are larger than d. c. losses, their ratio approaches unity with rising temp. A preliminary elec. test which can be substituted for "sludge test" is described. *Effect of intensity.*—The tangent of the loss angle increases nearly linearly with a. c. potential for materials without "ionization point." Dielec. const. is independent of the field strength except for transformer oil at 80°. When d. c. potential is applied the current increases rapidly at first, reaches a max., and then falls off gradually. The time required to reach the max. is inversely proportional to the applied voltage and proportional to the viscosity. *Effect of frequency.*—Dielec. const. is independent of frequency within the range tested, whereas dielec. loss increases or decreases linearly. The inclination of the lines is generally positive at low temps. and becomes smaller and finally negative as the temp. rises. The loss corresponding to zero frequency, obtained by extrapolation, coincides with the max. loss obtained with d. c. and its logarithm bears a linear relation to the reciprocal of the abs. temp. A somewhat complicated empiric formula for the loss angle is given with a table of the necessary constns. Tests on high-tension cables showed: (1) parallelism between loss angle and capacity with rise of applied voltage; (2) change of ionization point with the time of applied voltage; (3) frequency dependency of "V"-curves (loss angle-temp. curve), and (4) variation of wave form of the charging current with rise of elec. stress.

New measurements about the way in which the dielectric constant of liquid helium depends on the temperature. M. WOLFFE AND W. H. KESOM. *Proc. Acad. Sci. Amsterdam* 31, 800-6(1928).—See C. A. 22, 4348. E. H.

Ionization potentials and grating energies of atoms in the solid state. SUSIL CHANDRA BISWAS. *J. Indian Chem. Soc.* 5, 561-8(1928).—Assuming a Coulombian force of attraction and a repulsive force following an inverse-power law, B. develops the following equation to express the relationship between compressibility of a solid and its grating energy: $\beta^{1/4} W_{\text{pot}} = [A(n-1)^{1/4} \cdot 9^{1/4}] / n$, in which β is the compressibility of the crystal. W_{pot} is the potential energy in an elec. system of alternately pos. and neg. charges, A is Madelung's const. dependent on the lattice type, and n is Haber's repulsive coeff. A table shows that when the product of the ionization potential and $\beta^{1/4}$ for the elements of the first two groups of the periodic table is taken that two sets of consts. are found. Families IA, IIA and IIB are in one set and family IB is in the other. Data for Al, Tl, C, Pb, Mn, Fe and Ni are given. Haber's n for the alkalis is 2.4-3.6; for Cu, Ag and Au 8-9. This explains the two sets of consts. Sep. calcs. were made for: (a) evapn. of an electron, (b) evapn. of a positive ion and (c) hydration of a positive ion. Comparisons of these values among themselves and with exptl. data indicate that ionization of an individual gas atom and ionization of one of an assemblage of atoms in a crystal is the same process. F. E. BROWN

New superconductors. EDM. VAN AUBEL, W. J. DE HAAS AND J. VOOGD. Univ. Leiden. *Verslag. Akad. Wetenschappen Amsterdam* 37, 706-13(1928).—The conductivities of Cu_3Sb , Ag_3Sb , Ag_3Sn , Cu_3Sn , Bi_3Tl , Sb_3Sn and Sb_3Sn_2 were detd. from 0° to very low temps. At 0° the sp. resistivities $\times 10^3$ are: Cu_3Sb : 0.770; Ag_3Sb : 1.417; Ag_3Sn : 0.190; Cu_3Sn : 0.100; Bi_3Tl : 0.583; Sb_3Sn : 0.302; Sb_3Sn_2 : 0.250. At lower temps the values of R/R_0 are: Cu_3Sb : —24.52°, 0.9876; —44.27, 0.9771; —60.94, 0.9682; —79.29, 0.9583; —103.09, 0.9460; —116.61, 0.9386; —135.74, 0.9277; —149.65, 0.9195; —183.10, 0.8985; —198.93, 0.8886; —217.91, 0.8767; —252.66, 0.8596; —254.38, 0.8591; —256.62, 0.8587; —258.99, 0.8582. Ag_3Sb : —24.51, 0.9851; —44.27, 0.9728; —60.94, 0.9621; —79.32, 0.9501; —103.10, 0.9346; —116.62, 0.9254; —135.74, 0.9122; —149.66, 0.9023; —183.24, 0.8779; —198.93, 0.8657; —217.91, 0.8504; —252.66, 0.8262; —254.38, 0.8255; —256.62, 0.8247; —258.99, 0.8242. Ag_3Sn : —24.54, 0.9528; —44.27, 0.9148; —60.94, 0.8819; —79.34, 0.8453; —103.09, 0.7967; —116.61, 0.7686; —135.74, 0.7274; —149.65, 0.6963; —183.24, 0.6150; —198.93, 0.5729; —217.91, 0.5160; —252.66, 0.4054; —254.38, 0.4015; —256.62, 0.3972; —258.99, 0.3937. Cu_3Sn : —24.50, 0.9081; —44.27, 0.8417; —60.95, 0.7852; —79.32, 0.7224; —103.09, 0.6453; —116.61, 0.5976; —135.73, 0.5271; —149.66, 0.4760; —183.11, 0.3456; —198.94, 0.2801; —217.93, 0.2019; —252.65, 0.0998; —254.38, 0.0979; —256.62, 0.0961; —258.99, 0.0947. Bi_3Tl : —24.48, 0.9344; —44.28, 0.8811; —60.95, 0.8364; —79.29, 0.7871; —103.09, 0.7229; —116.61, 0.6864; —135.72, 0.6342; —149.67, 0.5962; —183.11, 0.5032; —198.93, 0.4582; —217.94, 0.4030; —252.66, 0.2978; —254.38, 0.2927; —256.62, 0.2865; —259.00, 0.2804. Sb_3Sn : —24.52, 0.9424; —44.28, 0.8962; —60.96, 0.8571; —79.29, 0.8149; —103.09, 0.7599; —116.61, 0.7286; —135.74, 0.6840; —149.66, 0.6512; —183.10, 0.5699; —198.94, 0.5297; —217.92, 0.4802; —252.66, 0.4029; —254.38, 0.4007; —256.62, 0.3984; —258.99, 0.3964. Sb_3Sn_2 : —24.53, 0.9333; —44.28, 0.8808; —60.95, 0.8363; —79.31, 0.7885; —103.09, 0.7265; —116.62, 0.6917; —135.74, 0.6417; —149.67, 0.6052; —183.10, 0.8163; —198.93, 0.4728; —217.86, 0.4199; —252.66, 0.3391; —254.38, 0.3368; —256.62, 0.3344; —258.99, 0.3323. The same compds. were then examd. in liquid He. Temps. are given in °K. and followed by the ratio R/R_0 : Bi_3Tl : 4.2, 0.0000. Sb_3Sn_2 : 4.20, 4.10, 4.00, 3.95, 3.80; 0.3257, 0.3196, 0.0637, 0.0062, 0.0000. Sb_3Sn : 4.20, 4.10, 4.00, 3.95, 3.80, 3.75, 3.73, 3.65, 3.55; 0.3917, 0.3911, 0.3672, 0.3080, 0.0927, 0.0616, 0.0537, 0.0349, 0.0261. Ag_3Sn : 4.22, 3.42, 3.00, 2.52, 1.99, 1.36; 0.3865, 0.3857, 0.3492, 0.2838, 0.2230, 0.1668. Cu_3Sn : 4.20, 3.80, 3.55, 2.89, 1.80, 1.54, 1.31; 0.095, 0.095, 0.095, 0.095, 0.093, 0.093, 0.092. It is thus shown that supercond. appears in the cases of Bi_3Tl and Sb_3Sn_2 . The temp. at which an alloy becomes superconductive is higher than that of its constituents. ALBERT L. HENNE

Measurements on the disturbance of the superconductivity of thallium by magnetic fields. W. TUIJN. *Proc. Acad. Sci. Amsterdam* 31, 687-91(1928).—See C. A. 22, 3822. E. H.

Properties of nickel-copper alloys at low temperatures. A. KRUPKOWSKI AND W. J. DE HAAS. Univ. Leiden. *Verslag. Akad. Wetenschappen Amsterdam* 37, 714-22(1928).—Several Ni-Cu alloys were prepd. and their sp. conductivities measured at decreasing temps.: Alloy with 2.08% Ni: $t = 0$, —183.10, —204.82, —252.60, —258.14; sp. resistivity ρ , in microhms/cm.: 3.8676, 2.3177, 2.0767, 1.6691, 1.6833. Alloy with

10.16% Ni: $t = 0$, -182.35, -204.56, -252.54, -258.33; $\rho_t = 13.8039$, 12.3049, 12.1118, 11.8752, 11.8816. Alloy with 19.27% Ni: $t = 0$, -182.81, -205.37, -252.52, -258.44; $\rho_t = 26.2314$, 24.7414, 24.5365, 24.3712, 24.4048. Alloy with 27.54% Ni: $t = 0$, -182.35, -204.56, -252.54, -258.34; $\rho_t = 34.5377$, 33.0830, 32.8685, 32.6754, 32.6970. Alloy with 32.85% Ni: $t = 0$, -183.10, -204.82, -252.63, -258.16; $\rho_t = 39.2349$, 38.0489, 37.8733, 37.6515, 37.6669. Alloy with 38.80% Ni: $t = 0$, -183.01, -205.18, -252.53, -258.39; $\rho_t = 44.4510$, 43.5804, 43.3964, 43.1719, 43.1348. Alloy with 43.45% Ni: $t = 0$, -183.00, -205.19, -252.53, -258.38; $\rho_t = 48.4480$, 47.6376, 47.3932, 46.6870, 46.3799. Alloy with 48.40% Ni: $t = 0$, -182.80, -205.37, -252.52, -258.44; $\rho_t = 50.1182$, 48.6904, 48.1011, 45.5189, 45.1860. Alloy with 57.45% Ni: $t = 0$, -183.10, -204.82, -252.60, -258.13; $\rho_t = 51.4360$, 43.6117, 42.1184, 39.5185, 39.3342. Alloy with 67.90% Ni: $t = 0$, -183.04, -205.07, -252.52, -258.38; $\rho_t = 44.4493$, 30.9304, 29.7221, 28.0419, 27.9572. Alloy with 86.64% Ni: $t = 0$, -182.83, -205.27, -252.52, -258.43; $\rho_t = 22.5152$, 14.2637, 13.6663, 12.9996, 12.9810. Ni 100%: $t = 0$, -182.44, -203.06, -252.57, -258.34; $\rho_t = 6.9330$, 1.2174, 0.8083, 0.2588, 0.2417.

The description of thermoelectric phenomena by a temperature-entropy diagram. KAMILLO KAMMERER. *Ann. Physik* 85, 948-58(1928).—The treatment of thermoelec. effects by the graphical method of Gibbs leads to a generalization of the thermodynamic laws covering thermoelec. effects.

F. R. BICHOWSKY

Thermal and electric conductivity of a copper crystal at various temperatures. W. G. KANNULUIK AND T. H. LABY. Univ. of Melbourne. *Proc. Roy. Soc. (London)* A121, 640-53(1928).—The thermal cond., λ , detd. by the thermal method, was found to be 0.989 cal./cm./sec./deg. at 19.4°, 1.054 at -73.7° and 1.131 at -174.8°. The value of λ at 19.4° is about 4% greater than that of polycrystal Cu, which agrees with Schott's results, while the values of λ at lower temps. are considerably less than Schott's values. In a high vacuum the heat losses were small and at room temp. they were eliminated by the correction detd. from the equation: $\Delta H = \frac{1}{2} \phi h l (\theta_0 + \theta_1 - 2\theta_s)$, where ΔH = lateral loss of heat from a section of Cu crystal rod of perimeter p , length l and temps. θ_0 and θ_1 at the resp. ends, h cal./cm./sec./deg. = the Fourier external cond., and θ_s = temp. of surrounding medium. The sp. elec. cond. K , at 90.1° K. was 311.6×10^4 ohm⁻¹ cm.⁻¹, a value slightly less than that of the purest polycrystal copper. The values of the Wiedemann-Franz const. $\lambda/(KT)$ were 1.69×10^{-8} watt ohm/deg.⁻² at 90.2° K. (Schott— 1.80×10^{-8}) and 2.42×10^{-8} at 273.2° K. (Schott— 2.42×10^{-8}).

H. W. WALKER

The thermoelectric Thomson effect at the temperatures of liquid hydrogen. G. BORELIUS, W. H. KEESOM AND C. H. JOHANSSON. Univ. Leiden. *Verslag. Akad. Wetenschappen Amsterdam* 37, 875-87(1928).—Measurements down to 20° abs. were made on 2 wires, Cu and Ag alloyed with a little Au, and down to 70° on pure Cu wire. The method was largely that of Borelius (*Ann. Physik* 65, 520(1921)), the ends of the wire being at const. temp., and the temp. of the center being varied by means of an elec. current through it. A Thomson effect is caused by the temp. gradient of a different sign for the 2 halves of the wire. The effect σ follows from $(\lambda/I)(\tau/\delta) - (3q^2/\epsilon)\phi$ in v. per degree for y , the distance in cm. of any point of the wire from the center, t the temp. increase by Joule heat, τ the same by Thomson effect heat, q the cross sectional area of the wire in sq. cm., λ the sp. heat cond. in watts per cm. degree, I the current in amps., ϕ a correction factor close to unity. The temps. t and τ were measured by thermocouples (Pt-constantan) in symmetrical points on the wire, the wire temp. was detd. by a Pt resistance thermometer. Careful precautions were taken against radiation, etc. The expts. were made *in vacuo*. It was necessary to det. λ at the exptl. temp. Values found were for the Cu alloy $\lambda = 1.44$ watt per cm. degree at 18.8° abs., 2.87 at 78.9°; for the Ag alloy 2.79 at 18.9° abs., 4.22 at 93.4°. From these values with those of other authors interpolation at the desired temp. was possible. The alloy wires consisted of Cu or Ag both with 0.37 atom % Au in order to make λ as much as possible independent of T . Considerable trouble was caused in the expts. by the Peltier heat of little inhomogeneous spots on the wires; it made σ appear dependent upon I and was eliminated by measuring σ at different I to find the true $\sigma = \sigma_{app.} + (\text{const.}/I^2)$. The final results obtained are tabulated at temps. $T = 20^\circ$ up to 300° abs. and are graphically represented. For the Cu alloy $\sigma \cdot 10^6$ goes from +0.44 at 20°, 1.39 at 30°, 2.17 at 40°, 2.84 at 50° through a max. of 2.96 at 60°. a min. of 1.71 at 130° and a steady rise to 2.33 at 300°. For the Ag alloy $\sigma \cdot 10^6$ is +0.31 at 20° it falls off to -0.03 at 50° and 60°, rises to +0.21 at 100° and continues to rise to 1.38 at 300°. For pure Cu $\sigma \cdot 10^6$ is -0.26 at 70°, min. of -0.49 at 90°, +0.02 at 140°, 1.52 at 300°. For further control of the values the thermoelec. forces were

measured of couples of the same metals. The thermo force per degree (microvolts) was found at 17.3° abs. for Cu alloy against Ag alloy +4.74, against Cu +4.80, against lead +3.75, at 70.6° for the same combinations +2.56, +3.49 and +1.31, at 280.7° +0.37, +0.87 and -2.11. From them by means of the equation $e_2 - e_1 = \int_{T_1}^{T_2} \left[\left(\frac{\sigma_2}{T} \right) - \left(\frac{\sigma_1}{T} \right) \right] dT$, the Thomson values were checked and found within the limits of error.

B. J. C. VAN DER HOEVEN

Preparation and study of noncrystalline piezoelectric substances. A. MEISSNER AND R. BECHMANN. Lab. Telefunkengesellschaft. *Z. tech. Physik* 9, 430-4(1928).—In order to prepare piezoelec. plates of noncryst. material, the pyro- and piezo-elec. qualities of several substances in powd. form were studied. The powder was spread out in a 1-2-mm. film on one electrode which could be heated and was covered with the second electrode. After "formation" of the film, *i. e.*, application of from 100 to 1000 v. and 3 to 7 min. waiting for dielec. after-effects, the powder was heated and its pyropotential detd. Tapping the electrode or heating it during the formation generally raised the pyropotential. For quartz powder a pyroelec. coeff. of 17.3×10^{-1} e. s. u. per cm.² degree was obtained by formation at 200° (ten times the value of solid plate quartz). This is explained by improved orientation of the unit SiO₂ cells. For SiO₂ powder the pyro effect (at 240°) is proportional to the potential and temp. of formation; it increases with decreasing grain size (0.15 to 0.6 mm.), and it is proportional to the temp. Repeated heating causes the formation effects to disappear. By formation at 650 v., 135°, and measurement at 135° the pyroelec. coeff. (times 10⁻¹) of the following substances was found: sugar 23.3, tartaric acid 8.1, Rochelle salt 7.4, tourmaline 20.5, topaz 27.5, ZnS 1.4, pyrite 1.8, pentaerythritol 9.48, cryst. quartz powder 17.3, amorphous quartz powder 11.2, purified quartz sand 6. To prepare plates with permanent pyro- and piezo-electricity quartz powder was imbedded in resins, formed at 1000 to 3000 v. and the potential maintained until complete solidification. The piezo coeff. of such plates was 50 to 70 times higher than that of solid quartz; part of this is due to the resin. The side of the plates positive during formation is at first negative on application of pressure but goes after a short period through zero to a positive piezo potential. The time necessary for this reversal depends on the resin used: it is a few mins. for carnauba wax, sealing wax, bakelite, Japan wax, beeswax, Venetian turpentine, tolu balsam, benzoin, several hrs for colophonium, Canada balsam, and S. The final piezo moment decreases with time at different rates; half the initial value is obtained for S and colophonium after 2 to 3 days, for beeswax, bakelite, Canada balsam 1 to 3 months, sealing wax, turpentine 4 months, electret (45% colophonium, 45% carnauba wax, 10% beeswax) more than 6 months. Plates prepd. of SiO₂ powder with asphalt do not change appreciably in 6 months. Satisfactory piezo-elec. microphones were made of these materials.

B. J. C. VAN DER HOEVEN

Determination of piezoelectric moduli of ammonium Seignette salt. W. MANDL. *Proc. Roy. Soc. (London)* A121, 130-40(1928).—The general math theory of piezoelectricity shows that for salts like Na(NH₄)C₄H₄O₆·4H₂O there are 3 piezoelectric moduli. These moduli were detd. exptly. for this salt. The results (multiplied by 10⁴) are: $d_{11} = +56.0$, $d_{22} = -149.5$ and $d_{33} = +28.3$. The corresponding values for the K salt are +1000, -165 and +35.4. The fact that the corresponding moduli for these two salts have the same sign is of interest because piezoelectricity and optical rotation are closely connected and the NH₄ salt is levo- while the K salt is dextro-rotary. The crystals undergo a slight decomposition at the surfaces on prolonged exposure to the atmosphere or to a drying agent. Expts. indicate no appreciable change in piezoelec. properties between -17 and +30°. Above 30° the loss of piezoelec. properties seems to be due to a viscous change rather than to any abrupt alteration in crystal structure.

W. W. STIFLER

Magneto-resistance effect in single crystals of nickel. SEIJI KAYA. *Sci. Repts. Tohoku Imp. Univ.* 17, 1st ser. 1027-37(1928); cf. *C. A.* 22, 4349.—Three rectangular rods were cut from a large single crystal of Ni, the axes of the rods being parallel to the (100), (110) and (111) axes of the crystal. The rods were 2.6 to 1.3 cm long and varied in cross-section from 1.5 to 1.0 sq. mm. When magnetized longitudinally by external fields up to 1400 gauss, all showed an increase in resistance. This occurred most rapidly and reached the largest value in the case of the (111) specimen, while the effect in the (100) specimen was least. The transverse effect was studied in fields up to 13,600 gauss. If magnetized along the (001) axis the (100) specimen first de-

creased in resistance, then increased more rapidly to a const. pos. value, but if magnetized along the (011) axis the resistance decreased, at first slowly, then more rapidly, and finally approached a negative value asymptotically. On varying the angle of the field, the change in resistance followed a sinusoidal law with max. corresponding to the (001) and the (010) directions and min. to the (011) and (01 $\bar{1}$) directions. For the (110) rod a somewhat similar result was obtained except that the max. for the (001) and (00 $\bar{1}$) directions were much greater than the max. for the (110) direction. For the (111) rod the max. occurred at the (11 $\bar{2}$), (2 $\bar{1}\bar{1}$), (1 $\bar{2}$ 1) and (1 $\bar{1}$ 2) directions, and the min. at (10 $\bar{1}$), (1 $\bar{1}$ 0) and (0 $\bar{1}$ 1).

W. W. STIFLER

Magnetostriction I. ALFRED SCHULZE. *Z. Physik* 50, 448-505(1928); cf. C. A. 22, 937.—Previous work, both exptl. and theoretical, on magnetostriction in ferromagnetic bodies is reviewed. A precise method for measuring magnetostriction is described and the theory underlying it developed. It is essentially an adaptation of Whiddington's ultra-micrometer method, based upon the change in capacity of an air condenser one plate of which is attached to the rod under examn. Change in capacity is measured by the frequency of the beat between the notes produced by two high-frequency circuits. The samples used were approx. 33 cm. long and 6 mm. in diam. Electrolytic Fe at first increases rapidly in length with increasing field and then reaches a max. length in a field strength of about 50 gauss. The rod then shortens more slowly, reaching the Villari point at about 225 gauss and continuing to shorten in still stronger fields. Two specimens of Fe, 99.7% and 98.6% pure, resp., gave similar results, with the Villari points at 265 and 420 gauss. Heat treatment modifies the magnitude of the effect in electrolytic Fe but does not change the position of the Villari point. In cast Fe there is no evidence of change in sign of the effect up to 370 gauss. The chem. and phys. consts. of the samples tested are described fully. In Co and Ni only a decrease in length occurs which in Co is not perceptible in fields less than 12 gauss, but in Ni is revealed in much smaller fields. At 300 gauss the effect in Ni is about 2.6 times as great as in Co. Since magnetostriction was absent in Bi it does not depend upon sp. resistance. Magnetostriction was measured and satn. values and initial permeabilities were calcd. for a series of Fe-Ni alloys varying from 3 to 90% Ni and contg. 4 to 1.8% Mn and traces of Si and C. When the Ni content is less than 80% the change in length is positive. There should be no magnetostriction in an alloy contg. 81% Ni. The curve of magnetostriction vs. Ni content has two maxima sepd. by a sharp min. at 30% Ni. Several of these alloys were tested after being annealed at 930° and the magnetostriction (in the reversible region) was found to be independent of the previous thermal treatment. The high initial permeability of permalloy therefore is not directly connected with its magnetostrictive properties. The intensity of magnetization and magnetostriction of these Fe-Ni alloys are completely analogous, but initial permeability and magnetostriction are not related. This is contrary to McKeehan's theory, which explains the high initial permeability of permalloy by the vanishing of magnetostriction. In a series of Fe-Si alloys contg. from 0.08 to 8.37% Si, the magnetostriction was found negative, with a max. at about 60 gauss in the alloy richest in Si, and positive in the alloys poorer in Si. A Villari point occurred at about 420 gauss in the alloy with 1.03% Si and at a considerably higher field strength in the alloy with 1.93% Si. In a series of Fe-Al alloys, contg. from 0.52 to 10.52% Al, the magnetostriction was always positive and increased with increase in Al content. At 0.52 and 1.04% Al there were indications of a Villari point near 400 gauss. At 300 gauss the effect for the 10.52% alloy was nearly 3 1/2 times as great as for the 5.66% Al alloy. The satn. value of the intensity of magnetization decreased almost linearly with increase in Al content. In both the Fe-Si and the Fe-Al series there were evidences of mixed crystals. A series of Fe-Mn alloys, contg. up to 14.5% Mn showed no direct correlation between Mn content and magnetostriction. The effect was positive or zero in all cases for fields below 250 gauss. In addition to the effects due to mixed crystals common to the series, an alloy containing approx. 8% Mn gave indications of instability which were attributed to an allotropic modification of Fe. While the exptl. results indicate an intimate relation between constitution and magnetostriction, no direct correlation can be established between magnetostriction and other physical properties.

W. W. STIFLER

Magnetostriction. L. W. MCKEEHAN. New Haven, U. S. A. *Z. Physik* 52, 752-4 (1928).—Reply to remarks by A. Schulze. (Cf. preceding abstract.) G. G.

Theoretical and experimental strength. M. POLANYI. Kaiser Wilhelm Inst. f. physik. Chem. u. Elektrochem., Berlin-Dahlem. *Naturwissenschaften* 16, 1043-4 (1928); cf. Joffe, C. A. 22, 518; 23, 1031; Polyani, C. A. 22, 2302.—A

of the results of Joffe and of P. on strengthening and elastic behavior of rock salt crystals. P. considers the strengthening an essential part of the behavior of rock salt under stress and denies the high compressive strengths of 25 and 100 kg. per sq. mm. assumed by Joffe from the behavior of crystal balls at 100° and 600°. At 100° P. found that plastic flow begins at a load of only 0.65 kg. per sq. mm., at 600° of 0.15 kg. per sq. mm. It is concluded that crystals differ from amorphous bodies in that forces smaller than calcd. from surface tension and mol. distances suffice for deformation. Strengthening effects appear which cause the elastic values of crystals to approach the theoretical ones only after prolonged deformation.

Internal strain produced when crystals of aluminum are extended. KEIJI YAMAGUCHI AND SAKUICHI TOGINO. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 668-82 (1928); *Abstracts* 1, 60-1.—When a test piece consisting of a single crystal of Al is extended at ordinary temp., the outward strain is far more uniform than at high temp. but Laue photographs show that a certain sort of strain has taken place in the interior of the crystal. So far as x-ray analysis is concerned, the internal strain is equivalent to a curvature of the crystal about an axis normal to the direction of slip on the slip plane. This is proved by the fact that when x-rays are projected parallel to the axis of this curvature, the corresponding Laue photograph presents spots accompanied by concentric tails. The axis of the curvature is perpendicular to one of the crystal faces (112) and the spot corresponding to this face displays a simple point without tail. The form of the tails (by incident x-rays perpendicular to the axis of curvature) agrees well with the diagram drawn from the calcn. by assuming the strain to be a rotation about the same axis. Since no change of angle (due to strain) between the axis of curvature and any crystal face can be shown, the form of the crystal lattice scarcely changes. The degree of curvature increases with extension, but Laue photographs are not adequate for quant. detn. In contradistinction with the rapid increase of the resistive strength of the crystal to slip following the increase of shearing strain, the degree of internal strain seems to increase proportionally to the strain. Although Polanyi (*Z. Physik* 12, 58(1923) and *C. A.* 22, 2302) says that the slip plane distorts into a conical form when the direction of the tangential component of the stress on the slip-plane does not agree with the slip direction, this does not hold in the case of Al. To ascertain this point, Laue photographs were taken along the axis of curvature as given by the hypothesis of his mode of explanation, but the results were negative. In order to explain the fact that the shearing strength of the crystal increases with an increase in strain by the elastic bending theory, quant. relations between the two must be ascertained. Till then, the bent slip set forth by Polanyi cannot be alone thought the chief cause of work hardening.

ALBERT L. HENNE

Density of molten metals and alloys. YOSHIHARU MATSUYAMA. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 1054-77(1928); *Abstracts* 1, 102.—The ds. of 5 molten metals (Sn, Cd, Bi, Pb, Zn), 7 binary alloys (Sn-Cd, Sn-Bi, Bi-Pb, Sn-Zn, Bi-Cd, Cd-Pb, Cd-Zn) and 6 ternary alloys (Sn-Bi-Cd, Bi-Cd-Pb, Sn-Bi-Pb, Sn-Cd-Pb, Sn-Cd-Zn, Cd-Pb-Zn) were measured at different temps. The expansion coeff. of a molten metal is almost independent of temp., but has a slight tendency to decrease with temp. rise. The d. of a molten metal at its m. p. was obtained by extrapolation of the d. temp. curve; the result coincides satisfactorily with the value calcd. from the expansion coeff. of the solid metal and the change of vol. during melting. In the case of a molten alloy, the at. vol. is greater than the mean of the at. vols. of the components. The concn. corresponding to the max. deviation from the linear relation of the at. vol. is not 50 at. %, but is displaced towards the side of the component of smaller d. The amount of the max. deviation is of the order of 1%. The equation of J. J. van Laar and R. Lorenze for heat of mixture may hold good in the cases of Sn-Cd, Pb-Cd, Sn-Zn and Cd-Zn. The writer also measured the thermal expansion of glass to obtain the necessary correction, and found a transformation in glass.

Densities of liquid elements. L. H. BORGSTRÖM. *Finska Kemistamfundels Medd.* 36, 76-81(1927).—A comparison.

H. G.

The surface tension of liquid sulfur dioxide. VERNON M. STOWE. *Univ. of Minn. J. Am. Chem. Soc.* 51, 410-5(1929).—The surface tension of liquid SO₂ was measured by the capillary-height method over a temp. range of -80° to 50° (the data are rather inconsistent in the region -80° to -20°). The radii of the capillaries were ascertained by detn. of the rise of CCl₄ in them, assuming validity of Richards and Carver's data (*C. A.* 15, 1841), from the wt. of a Hg thread of known length; and by direct measurement with a microscope fitted with a micrometer scale. The data secured by the 3 methods agreed with a max. deviation of 2.3% (average deviation about 1.0%). The equation of Ferguson (van der Waals) in the form $\gamma = 0.061584 (157.5 - t)^{1.2}$ fits the

data with an accuracy of 0.5% in the range -20° to 50° ; the Ramsay-Shields const. calcd. for the temps. is 2.134.

WILLIAM E. VAUGHAN

Investigations of surface tension constants in an homologous series from the point of view of surface orientation. K. W. HUNTEN AND O. MAASS. McGill Univ., Toronto. *J. Am. Chem. Soc.* 51, 153-65(1929).—The surface tensions and ds. of propionic, butyric, caproic, caprylic, capric, lauric, myristic, palmitic, margaric and stearic acids and of dicetyl were measured over 100° ranges of temp. The surface tensions are claimed to be accurate to 0.5% and the ds. to 0.05%. (The data in the case of the surface tension of caprylic acid vary more than this limit among themselves.) The angle of contact of these substances was found to be zero. The viscosities of palmitic, stearic and margaric acids were detd. From the graphs the Eötvös consts. of these materials were found. The total surface energy approaches a series const. more rapidly in the fatty acids than in the paraffins. The Eötvös or Ramsay-Shields term increases rapidly in the case of the fatty acids and has an abnormally high value for the higher paraffins. The variation in the R.-S. const. parallels Sugden's parachor. Partial orientation on the surfaces of pure liquids is possible.

WILLIAM E. VAUGHAN

Surface energy and the orientation of molecules in surfaces as revealed by surface energy relations. WILLIAM D. HARKINS. *Z. physik. Chem., Abt. A*, 139, 647-91 (1928).—The work of Haber and his associates on the orientation of mols. in surfaces as related to surface energy is reviewed. The fundamental theory and certain thermodynamic features are discussed at length. A complete bibliography of the author's publications in this field is included.

J. B. AUSTIN

The electric double layer of metals. YA. FRENKEL. *Z. Physik* 51, 232-8(1928).—The old theory of the surface double layer is re-stated in terms of wave mechanics and Fermi statistics. The results have only qual. significance, since the assumption of uniform potential is not in accord with modern ideas of a crystal lattice.

F. R. BICHOWSKY

The effect of gas on the electrical double layer of aqueous solutions. ALFONS BÜHL. Univ. Heidelberg. *Ann. Physik* 87, 877-908(1928); cf. *C. A.* 22, 533.—Evidence that the double layer is situated entirely within the liquid is cited and discussed. The cond. of H_2O and of dil. solns. (KCl, NaCl and LiCl at concns. of from 0.0001 to 0.01 *N*) was shown to be the same, within narrow limits, when the solns. contained dissolved gases (N_2 , O_2 or H_2) as when they were gas-free. It was concluded that the liquid junction potential at the boundary between a gas-contg. and a gas-free soln. of the same salt at the same concn. should be zero. This conclusion was tested by measuring the e. m. f. between two calomel electrodes, one in the gas-contg. and the other in the gas-free soln., connected by a capillary siphon. This cell had an e. m. f. of zero within 0.05 mv. The potential difference of the elec. double layer at the surface of a dil. alkali chloride soln. is not influenced by the adjacent gas but is increased by a dissolved gas. This increase depends on the electrolyte concn. and requires time for its formation. The conception of the arrangement of the elec. charge in the double layer is extended and discussed.

E. R. SMITH

Method of moving boundaries as applied to the measurement of the absolute velocity and the transport number of ions and of the rate of migration of colloidal particles. JNANENDRA NATH MITTHERJEE. *J. Indian Chem. Soc.* 5, 593-607(1928).—A general discussion with no new data. M. concludes that the theoretical basis of methods of cataphoretic speed must rest on securing a "uniform ionic environment during the movement of the colloidal particles."

F. E. BROWN

The application of Langmuir's theory to the adsorption of gases by charcoal. M. POLANYI. Kaiser Wilh.-Inst. f. physik. Chem. u. Elektrochem. *Z. physik. Chem., Abt. A*, 138 459-62(1928).—Zeise, *C. A.* 23, 557, found that isotherms for the adsorption of gases by charcoal can be expressed by Langmuir's adsorption formula and urged this as proof of the correctness of L.'s theory. However, the theory requires that one of the two consts. of L.'s formula be independent of temp. and that the other decrease exponentially with temp. Since expt. reveals that neither const. behaves in the required way, L.'s theory must be rejected. The discrepancies cited by Z. against P.'s theory can be accounted for satisfactorily and there is other exptl. evidence that confirms it.

F. L. BROWNE

Adsorption phenomena in solutions. XVII. The different modifications of activated charcoal. MICHAEL DUBININ. Tech. Hochschule, Moscow. *Z. physik. Chem., Abt. A*, 140, 81-8(1929); cf. *C. A.* 22, 3329.—Sugar charcoal has different adsorbing properties according to the temp. at which it is activated. A charcoal activated at 550° adsorbed mineral acids from aq. solns. of equiv. concn. in the order $HCl < H_2SO_4 < H_3PO_4$ and org. acids according to Traube's rule, i. e., propionic < valeric < hep-

tylic acid. This is called *covalent adsorption*. A charcoal activated at 800° adsorbed both the mineral and the org. acids in the reversed order. This is called *oriented adsorption*. The difference between the charcoals probably lies in the formation of amorphous C at the surfaces of the one activated at 550° and a fine cryst. C at the surfaces of the one activated at 800°. Neither charcoal adsorbs alkali when free from CO₂. An active charcoal of the cryst. type was made by careful heating of a raw wood charcoal.

F. L. BROWNE

The heat of adsorption of oxygen on charcoal. III. DOUGLAS MCKIE. *J. Chem. Soc.* 1928, 2870-89; cf. *C. A.* 22, 531.—A method is described for measuring the heat of adsorption of gases on solid surfaces and the details of construction of a *vacuum calorimeter* are given. Measurements are reported on the heat of adsorption of O₂ on C. The mean molar heat varies from 70 cal. at 20° to 116 cal. at 200°. J. B. A.

Behavior, with regard to time, of the adsorption on silica gels of gaseous mixtures containing alcohol and ether in addition to air. I. LADISLAUS VON PLETNOKY AND GEZA VON SZELNYI. *Z. Elektrochem.* 34, 805-13(1928).—A new dynamic method was devised, suitable for measuring the adsorption of alc. and Et₂O. A 3-chamber gas interferometer was used as analyzing instrument. The adsorption was measured on 5 samples of com. SiO₂ and one sample prepd. by hydrolysis of SiCl₄. The simultaneous adsorption of alc. and Et₂O from air depends on the abs. amt. of these compds. in the atm. and on their relative amts. The ratio: alc./ether in the vapor is not the same as that in the adsorbed phase; they are interdependent, and the former is always smaller than the latter. The relative concns. in the vapors can be so adjusted that the ratio of the adsorbed amts. will equal 1; these concns. are the same with every sample of SiO₂ used; they are little affected by the abs. concns. The adsorption velocity decreases with time, but the ratio: adsorbed alc./adsorbed Et₂O remains nearly const. throughout.

ALBERT L. HENNE

Thermal and magnetic investigations on absorbed gases. FRANZ SIMON. *Z. Elektrochem.* 34, 528-31(1928).—Investigations by S. and his collaborators on the absorption of A and H₂ by chabasite are reviewed. By heating chabasite at reduced pressure the H₂O originally contained in it can be driven out without disturbing the crystal lattice, leaving a sort of honey-comb structure. The absorption isotherm for A, at 90° abs. and concns. from 0 to 1.5 mols. per mol. of chabasite shows a definite break at 1 mol. This indicates an integral no. of gas mols. in each cell. Measurements of the magnetic susceptibility of chabasite contg. various amts. of adsorbed O₂ confirm the conclusion. The curves of susceptibility vs. adsorbed O₂ show definite breaks at 1 and 2 mols. of O₂ per mol. of chabasite. While these results indicate a uniform distribution of gas mols. throughout the cells, the question remains whether the gas mols. are relatively firmly bound in the interior of the cells or are free to move therein. Sp. heat measurements now in progress should make it possible to distinguish between these two cases since the degrees of freedom are different. Some results for the mol. heat of absorbed H₂ at about the temp. of liq. N₂ show no clear relationships. The behavior of "electron gases" in metals is also mentioned.

W. W. S.

Studies in adsorption. XXII. The adsorption of Cu and of cupric salts in the precipitation of cupric hydroxide. M. R. MEHROTRA and N. R. DHAR. Allahabad Univ., India. *J. Phys. Chem.* 33, 216-25(1929); cf. *C. A.* 22, 1073.—The object of the study was to det. whether the high results obtained in estg. Cu by pptn. of sol. Cu salts with NaOH or KOH and igniting the ppt. are due to adsorbed alkali. Cu(OH)₂ pptd. from solns. of CuSO₄ or CuCl₂ adsorbs KOH or NaOH and the ppt. from CuCl₂ adsorbs more alkali than that from CuSO₄. Both Cu⁺⁺ and SO₄⁻⁻ are adsorbed by Cu(OH)₂, the 2 ions in equiv. amt. CuCl₂ is similarly adsorbed. Because of this adsorption Cu is completely pptd. from soln. by slightly less than the equiv. amt. of alkali. The adsorption data suggest a compd. 3Cu(OH)₂.CuSO₄. For the adsorption of NaOH and KOH the formula, $a = A[(KC)^{1/n}/(1 + (KC)^{1/n})]$, holds in which a is the amt. adsorbed, A the max. adsorption, and K and n are consts.

F. L. B.

Adsorption of ions by sols of aluminum hydroxide and vanadimumpent oxide. D. N. CHAKRAVARTI AND N. R. DHAR. Allahabad and Nagpur. *J. Indian Chem. Soc.* 5, 539-43(1928).—The adsorption equation of C. and D. (cf. *C. A.* 22, 1073, 3079) agrees better with the results of adsorption expts. on Al₂O₃ and on V₂O₅ than the adsorptions calcd. by Freundlich's equation. The order of adsorption of anions on Al₂O₃ was: BrO₃⁻ > Cl⁻ > IO₃⁻ > CrO₄⁻⁻ > Fe(CN)₆⁻⁻ > C₂O₄⁻⁻. A sol of V₂O₅ adsorbed more K⁺ than it adsorbed bivalent and multivalent radicals.

The physical basis of Naegeli's micella theory. H. MARK. *Naturwissenschaften* 892-900(1928).—A review of optical methods (ultramicroscopy and polarization) qual. examn. of micellae and the newer x-ray methods which give quant. data their structure. The structure of cellulose is specially discussed.

B. J. C. VAN DER HOEVEN

Studies on permeability. Friction constant, interfacial tension and surface layer. J. TRAUBE AND SIAR-HONG WHANG. *Techn. Hochschule, Berlin. Biochem. Z.* 203, 363-9(1928); cf. *C. A.* 23, 749.—The rate of flow of aq. solns. of capillary-active substances varies inversely as the surface tension. The permeability and resorption of a substance thus depend upon its surface tension activity or polarity, also on the activity of the wall.

S. MORGULIS

Membranes for ultrafiltration, of graduated fineness down to molecular sieves.

MCBAIN AND S. S. KISTLER. *Stanford Univ. J. Gen. Physiol.* 12, 187-200

Cellophane, which consists of cellulose and a trace of glycerol, and may be in sheets, is recommended for membranes in ultrafiltration. After swelling in water, it retains the finest colloidal particles but permits mols. such as sucrose to pass. Dense ultrafilters may be made (1) by clogging the cellophane membrane with a suspension of cellulose in water, the suspension being formed by dilg. cellulose in Schweitzer reagent, and (2) by filtering a suspension of cellulose through a membrane that has previously been swollen in water. The behavior of cellophane in aq. and non-aq. solutions. Such membranes may be used for ultra-filtration but do not differ from other membranes. A membrane from cow's intestine, filters rapidly colloids. Different types of membranes may be prepd. by drying it to dry until brittle. Porosity increases with swelling.

Such membranes will retain a fair proportion of colloids. The chief factor in ultrafiltration. The relation to diffusion, dialysis, osmosis, electro-

The influence of mixtures of electrolytes on the viscosity of sols of lyophilic substances. H. J. C. TENDELOO. *Rec. trav. chim.* 48, 23-8(1929).—Expts. on prote

that the influence of electrolytes on the viscosity of lyophilic sols is of

character. Ions alter the elec. charge of the micelles which corresponds to a diminution of the degree of hydration. The magnitude of the effect depends upon the valence of the ions absorbed. KCl , $BaCl_2$ and $Co(NH_3)_6Cl_3$ being used, the influence of different concns. and mixts. on the viscosity of a 1% sol of gum arabic was detd. If a single electrolyte is added, the viscosity decreases as the valence of the anion increases or the concn. of the electrolyte increases. The effect of equiv. concns. of mixed electrolytes is additive. The influence seems proportional to the total amt. of electrolytes present.

DON BROUSE

The coagulation of rod-shaped colloids by electrolytes. I. Rapid perikinetic coagulation. GEORG WIEGNER AND C. E. MARSHALL. Tech. Hochschule, Zürich. *Z. physik. Chem., Abt. A*, 140, 1-38(1929).—The coagulation was observed by counting the particles in the slit ultramicroscope, orienting the rod-shaped ultramicrosols at right angles to the illuminating light by means of an a. c., so that all particles were visible. Coagulation of V_2O_5 sols and of benzopurpurin sols, in which the particles are rod-shaped, takes place more rapidly than in sols with spherical particles, but benzopurpurin sols with approx. spherical particles exhibit normal rapid coagulation, conforming to v. Smoluchowski's theory. The abnormally rapid coagulation of rod-shaped particles does not depend upon the chem. nature of either sol or coagulant. At the beginning of the coagulation it is more rapid the greater the ratio of length to thickness of the particles and the greater the initial no. of particles in the sol. As rapid coagulation progresses, the secondary particles that are formed continue to coagulate less rapidly until finally they follow v. S.'s theory. The velocity of rapid coagulation of the secondary particles is influenced by shaking the sol but that of the primary particles is much less so. II. Slow perikinetic coagulation. *Ibid* 39-63.—In amicroscopic and submicroscopic sols of benzopurpurin AB slowly coagulated with $NaCl$, v. S.'s law was followed as long as the particles were spherical. Shaking had less influence on the slow than on the rapid coagulation. In a typically rod-shaped V_2O_5 sol slow coagulation took place more rapidly in the early stages of the process than in the later, just as was found for rapid coagulation. In the early stages, slow coagulation of rod-shaped particles may be faster than rapid coagulation of spherical particles. On passing gradually from rapid to slow coagulation by adding $NaCl$ the retarding of the rate of coagulation is more marked for rod-shaped than for spherical particles. The relation between concn. of coagulant and no. of particles present after a definite time interval is the same for rod-shaped V_2O_5 particles as it is for spherical lyophobic particles in general. In benzopurpurin sols aged in the presence of small quantities of $NaCl$, the particles become more nearly spherical and the coagulation departs less from v. S.'s law.

F. L. BROWNE

The effect of non-electrolytes on the coagulation of colloids. III. Copper ferro cyanide sol. SUBODH GOBINDA CHAUDHURY AND NIRMALA PADA CHATTERJEE. Univ. Calcutta, India. *J. Phys. Chem.* 33, 244-9(1929); cf. *C. A.* 23, 1332.—The influence of $MeOH$, $EtOH$, urea, cane sugar, gelatin and H_2O_2 on the coagulating concns. of HCl , H_2SO_4 , citric acid, KCl , $BaCl_2$, and $AlCl_3$ for $Cu_2Fe(CN)_6$ sol were detd. The results are compared with previous studies with As_2S_3 and $Fe(OH)_3$ sols. "It is obvious that several factors are at work and that it is *a priori* difficult to predict what is going to happen in a particular case. The specificity of stabilizing or sensitizing effect is to be attributed to the fact that what we observe is the net result of changes in a large no. of variables which affect the coagulating concn." "It is unjustifiable to discuss the observations on coagulation with mixts. of electrolytes and in the presence of non-electrolytes on the basis of amts. of adsorption of the coagulating ion necessary for coagulation as affected by simple considerations in changes in adsorbability or variation in the original charge. . . . There are other equally influential factors such as the elec. forces opposing collisions, the elec. adsorbability, the changes in the energy associated with the agglomeration of the particles, and most of all the change in the critical potential of the sol on the addn. of a non-electrolyte."

F. L. BROWNE

Further studies on the precipitating action of protective colloids. E. MENEGHETTI. *Boll. soc. ital. biol. sper.* 3, 779-81(1928).—Colloidal Sb_2S_3 was made by bubbling H_2S through a soln. of $K(SbO)$ tartrate in the presence of gelatin. The max. concn. of colloidal Sb_2S_3 depends upon the amt. of gelatin used as a protective colloid. When the concn. of gelatin in % is, resp., 0, 0.47, 0.88, 1.68, and 3.80, the max. concn. of Sb_2S_3 is 0.304, 0.151, 0.308, 0.404 and 0.607%. Although in sufficient concn. gelatin exerts a protective action, in small amts. it reduces the max. concn. of Sb_2S_3 in solution.

PETER MASUCCI

Sol and gel transformations by mechanical working. H. FREUNDLICH. *Kolloid Z.* 107, 288-99(1928).—F. believes sol and gel closely related and that the fluid state

is always the dispersion medium from expts. with gels transformable by mech. work into sol which again gel on standing. The effect of p_H and of added electrolytes on gelling time is discussed. Such transformable gels, i. e., *thixotropic* gels, show double refraction in the moving sol indicating some attractive forces between the particles. $Fe(OH)_3$ and $Al(OH)_3$ gels are the best examples although gelatin may be made to behave in the same manner. This transformation occurs in biol. media and is hence of great importance.

L. F. MAREK

Free and bound fluid in gels. W. B. HARDY. *Kolloid Z.* 46, 268-77(1928).—Attraction between ions of a soln. due to elec. properties is a special case of cohesion. This attraction is great enough to affect vapor pressure and f. p. and is measurable through such changes. It is selective. H. believes that the range of cohesion at the surface of steel, copper, glass or quartz is large and is the sum of the attractions of the individual mols. The effect of orientation is to increase cohesion range. To demonstrate bound water H. describes effects obtained in freezing a gelatin gel. Frozen joints of a lubricant between metal surfaces are broken to show the range of influence of metal in preventing crystn. in the adsorbed material. Bound fluid is that which is held more strongly by the dispersed particles than by any other phase present. A gel with positive syneresis is one in which the attraction of the dispersed phase for itself is greater than its attraction for dispersion medium. A study of the range of surface attraction in colloids is of more importance than that of the question of whether a colloidal particle is cryst. or amorphous.

L. F. MAREK

Syneresis. ALFRED KUHN. *Kolloid Z.* 46, 299-314(1928).—The hydration equil. may be approached from both sides, i. e., by syneresis or by swelling. Results of syneresis expts. of others are reviewed. The influences of temp., dispersing medium, alcohol, admixtures, mech. treatment, surface area, etc., are discussed with reference to various exptl. results. Composition of expressed fluid is discussed. From theoretical standpoints syneresis is analogous to crystn., is due to decrease in adsorption, and results in structural changes due to desolvation.

L. F. MAREK

Thermal, mechanical, and x-ray analysis of swelling. R. O. HERZOG AND K. WISSENBERG. *Kolloid Z.* 46, 277-89(1928).—Gels and jellies may be analyzed from material and energy standpoints. With the aid of physical and chem. methods the structure of the micelle, molecule and atom has been studied. In the thermodynamic analysis the system is looked on as a single homogeneous phase and the changes due to energy additions are studied. Mech. energy is divided into elastic energy and a combination of kinetic and heat energy. The kinetic theory involves consideration of translatory, rotational and oscillatory energy of the gel. By optical means the system is divided into phases which are then studied individually. Swelling phenomena are associated with chem. interaction and the consequent changes in aggregation are due to formation of a new substance. Orientation plays an important part in detg. structural characteristics.

E. SCHOTTE

The influence of the solvent on optical rotational dispersion. A. L. TH. MOESVELD. Univ. Utrecht. *Verslag. Akad. Wetenschappen Amsterdam* 37, 823-34(1928).—It was found that for bornyl acetate in various solvents the rotation α_λ can be represented by a single Drude term $k/(\lambda^2 - \lambda_0^2)$ and thus the influence of the solvent expressed in k and λ_0 . The const. k depends upon the stiffness of the vibrating system and deviations of k can be expected whenever considerable deformations of the mol. take place, especially in the case of mixed solvents which are differently attracted by the 2 sides of the solute mol. For the exptl. work a monochromator according to van Cittert was used with arc light. The polarization app. was that of Landolt-Lippich with a plate field and 22.0-cm. tube at 30.0°. Seven colors were used close to known crystal spectral lines; the wave lengths were checked by a standardized quartz plate (Lorenz equation). The bornyl acetate was carefully purified; it m. 27.7 and 715. The accuracy of the angle measurements was better than 0.03°.

For the Drude const. of pure bornyl acetate at 30.0° was found $k = 13.75$, $\lambda_0^2 = 0.03236$. The solns. of bornyl acetate contained usually 20% ester (20 g. per 100 cc.) and followed Drude's equation within 0.2%. In abs. alc. $k = 14.17$, $\lambda_0^2 = 0.03383$ (20% soln.). For a 5% soln. $k = 14.86$, $\lambda_0^2 = 0.02195$ and for a 1% soln. 15.32 and 0.02163, indicating that more alc. mols. are available for each ester mol.; consequently there is more distortion. If enough water is added in a water-alc. mixt. to make the 20% ester soln. a satd. one (38.5% water, 61.5% alc.) k was found to be 14.58, $\lambda_0^2 = 0.2990$. For a 20% soln. was found in AcOH $k = 14.84$, $\lambda_0^2 = 0.03052$; in heptane 13.79, 0.03277; AcOH-heptane 1:1 14.94, 0.03036; nonane 13.82, 0.03253; AcOH-nonane 1:1 14.79, 0.03108; PhH 12.72, 0.03349; AcOH-PhH 1:1 14.24, 0.02904; decalin 13.80, 0.03067; AcOH-decalin 1:1 14.74, 0.03341; EtOH-decalin 1:1 14.55, 0.03154; benzyl alcohol 13.88, 0.03388; benzyl alcohol-heptane 1:1 14.26, 0.03162; decalin-PhH 1:1 13.07, 0.03190; EtOH-PhH 1:1 13.84, 0.03138; benzyl alcohol-EtOH 1:1 14.36, 0.02735; benzyl alcohol-decalin 1:1 14.29, 0.03163; decalin-heptane 1:1 13.79, 0.03145; PhH-benzyl alcohol 1:1 13.59, 0.3419; PhH-heptane 1:1 13.27, 0.02855. In the most indifferent media such as heptane and decalin the value 13.79 is equal to that of the pure ester where there is no deformation. PhH and AcOH have opposite effects, resp., lowering and raising k , due to the localization of forces on the Ph and the AcO group of the ester. The action of benzyl alcohol is small because of internal compensation of these effects. EtOH raises k slightly. Mixing of indifferent media gives nearly additive results but large discrepancies appear for mixts. with AcOH (specially PhH-AcOH) indicative of the above-mentioned effect of increased deformation. In those mixts. where the solute induced complete mixing of the originally immiscible solvent components (EtOH-decalin, benzyl alcohol-PhH) the discrepancy is more than 3%. The values found were always larger than those calcd. for simple mixing.

B. J. C. VAN DER HOEVEN

Separation of thorium and uranium by means of ether. P. MISCIATTELLI. *Atti accad. Lincei* 7, 1019-24(1928).--The literature shows a difference of opinion on whether U and Th may be sep'd. by means of Et₂O. In order to help solve the problem, M. measures the solubilities of UO₂(NO₃)₂ and Th(NO₃)₄ in Et₂O, as follows:

Compn. of upper layer			Compn. of lower layer		
UO ₂ (NO ₃) ₂	Th(NO ₃) ₄	Et ₂ O	UO ₂ (NO ₃) ₂	Th(NO ₃) ₄	Et ₂ O
22%	0%	78%	—	—	—
22.5	1.02	76.48	40.1%	0.52%	59.38%
24	3.5	72.57	48.3	15.6	36.1
24	3.43	72.50	43	20	37
19.2	4.5	76.3	12	40	48
18	5	77	—	—	—
16.5	5.6	77.90	13	27	60
12.2	7	81	9	30	61
8.2	8.3	82.5	7	26	67
3	8	89	1.8	48.5	39
0	5.8	94.2	—	—	—

A small amt. of Th increases the soly. of U. The satd. soln. contains 24% U salt, 3.4% Th salt. The variation of the satd. soln. with temp. is shown below.

Temp.	Compn. of soln.			Compn. of soln.		
	UO ₂ (NO ₃) ₂	Th(NO ₃) ₄	Et ₂ O	UO ₂ (NO ₃) ₂	Th(NO ₃) ₄	Et ₂ O
0°	24%	3.43%	72.57%	48.3%	15.6%	36.1%
16	17.7	1.7	80.6	28.2	20.4	51.4
19	10.5	0.4	89.1	39.2	15	46.8
20	8.78	—	91.22	15.5	26	58.5
22	8	—	92	13.2	23	63.8
25	7.37	—	92.63	12.2	30	57.8

Therefore, at 20° it is possible to sep. the two, providing the Et₂O is satd. with U salt.

A. W. CONTIERI

Effect of neutral salts on the rotary power of tartaric acid and of the tartrates. E. DARMOIS. *Ann. phys.* 10, 70-115(1928).—The large variations in the sp. rotatory power (α) of H₂C₄H₄O₆ with the concn., temp., and addition of neutral salts have been ascribed heretofore to the presence of two or three active forms of the acid having different rotations and dispersions. In mixts. of H₂C₄H₄O₆ and CaCl₂ the variation in (α) followed closely that of the H⁺ ion concn., indicating that, in this case, the degree of disson. of the acid was the important factor rather than the relative proportion of two hypothetical forms of the acid. An attempt to establish the existence

of these hypothetical forms of $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$ requires first a study of α for the $\text{C}_4\text{H}_4\text{O}_6^{--}$ ion. For this purpose α was detd. in solns. of different concn. of the neutral tartrates of the elements of the first three groups of the periodic table. The tartrates which are insol. in H_2O are usually sol. in the presence of an excess of a salt of the metal, and were thus studied. Although these tartrates may be considered largely dissociated in soln., α is not independent of the concn.; and it varies in a regular manner on passing from one element to the following one in the periodic system. These variations are thought to be the resultant of several effects: (1) A dehydration of the ion $\text{C}_4\text{H}_4\text{O}_6^{--}$ in the presence of the cations of the added salt, which increases α . (2) A deformation of the ion $\text{C}_4\text{H}_4\text{O}_6^{--}$ in the field of the other ions, especially the cations. This is the most important effect; it may be demonstrated in the presence of any salt of a metal; and it is large enough in some cases to cause a reversal of the sign of α . The deformation increases with the charge of the ion for cations having the structure of the rare gases. (3) An assocn. of the two ions of the tartrate occurs, especially in the case of multivalent ions. Because of this assocn. in concd. soln. the deformation mentioned in (2) does not increase indefinitely as the concn. increases. The elements Cu, Zn, Hg, etc., which have a structure quite different from that of the alkalis and the alk. earths, give more or less complex tartrates. In fact, the rotary power of the ion $\text{C}_4\text{H}_4\text{O}_6^{--}$ has proved to be a reagent very sensitive to the field of the ions present with it in soln., and by its use one may detect certain deformations and associations postulated by Fajans and Bjerrum for strong electrolytes. The study of the sp. rotary power is a valuable aid in furthering our general knowledge of electrolytes. The above detailed study of the $\text{C}_4\text{H}_4\text{O}_6^{--}$ ion does not permit fixing definitely the forms present in a soln. of $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$, but it does demonstrate the variable sp. rotary power of this ion, further study of which may lead to a more complete knowledge of the still enigmatic substance, tartaric acid.

R. H. LOMBARD

Crystal growth in aqueous solutions. I. Theory. WARREN L. McCABE. Univ. of Michigan. *Ind. Eng. Chem.* 21, 30-3(1929).—Equations are developed for calcg. the yield and screen analysis of crystals obtained when seed crystals of known wt. and size are suspended in the satd. soln. which is cooled under controlled conditions. It is assumed that no new nuclei are formed and that the wt. of solid phase sepg. can be calcd. from the amt. of soln., the change in temp., and the change in soly. with temp. It is further assumed, with theoretical substantiation, that all geometrically similar seed crystals grow at the same rate in each of their linear dimensions, regardless of the original size of the crystals. **II. Experimental.** *Ibid* 112-9.—Seed crystals of known wt. and screen analysis were suspended in satd. soln. at const. temp. for 18 hrs., then removed, weighed and screened. There was no tendency for large crystals to grow at the expense of small ones although there was a 5-fold difference in size. Of 31 expts., 12 were incomplete or obviously inaccurate and 19 satisfactory, of which 13 were made with KCl needles, 3 with KCl spheres and 3 with $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$. Exptl. study of 10 variables verified the basic postulate of the theory that during crystn. all of the crystals grow but the distribution of their relative sizes remains the same.

W. C. EBAUGH

Solubility of magnesium carbonate in aqueous solutions charged with carbonic acid gas. KIYOMATSU TERADA. *Bull. Inst. Phys. Chem. Research* (Tokyo) 7, 452-65 (1928); *Abstracts* 1, 41-2.— MgO , $\text{MgCO}_3 \cdot 3\text{H}_2\text{O}$ and the basic carbonates have widely different soln. velocities in H_2O charged with CO_2 . MgO or Mg(OH)_2 dissolves quickly in H_2O whose satn. with CO_2 is maintained; a state of supersatn. is reached, a metastable soln. of $\text{Mg(HCO}_3)_2$ being formed. $\text{MgCO}_3 \cdot 3\text{H}_2\text{O}$ dissolves slowly and no metastable soln. is yielded. The soly. curve shows that the transition point: $\text{MgCO}_3 \cdot 5\text{H}_2\text{O}$ to $\text{MgCO}_3 \cdot 3\text{H}_2\text{O}$ is at 13.5° . Basic carbonates dissolve very slowly and are not easily transformed into neutral carbonates. The above-mentioned metastable soln. decomposes readily by addn. of some MgCO_3 crystals, giving off CO_2 and pptg. $\text{MgCO}_3 \cdot 5\text{H}_2\text{O}$, $\text{MgCO}_3 \cdot 3\text{H}_2\text{O}$ or basic carbonates. The soly. of $4\text{MgCO}_3 \cdot \text{Mg(OH)}_2 \cdot 3\text{H}_2\text{O}$ is lower than that of $\text{MgCO}_3 \cdot 4\text{H}_2\text{O}$ except near 0° . The transition point: $4\text{MgCO}_3 \cdot \text{Mg(OH)}_2 \cdot 5\text{H}_2\text{O}$ to $4\text{MgCO}_3 \cdot \text{Mg(OH)}_2 \cdot 4\text{H}_2\text{O}$ is at 29° . Under high CO_2 pressure, MgO dissolves readily, forming a supersatd. soln.

ALBERT L. HENNE

Solubility of calcium sulfate from 0° to 200° . EVERETT P. PARTRIDGE AND ALFRED H. WHITE. Univ. of Michigan. *J. Am. Chem. Soc.* 51, 360-70(1929).—Values for the soly. of CaSO_4 in H_2O between 100° and 200° were redetd. Within this range gypsum and anhydrite are the only stable phases. The transition temp. of gypsum into anhydrite lies near 40° . Hemihydrate is metastable in the range 90 – 130° , showing decreasing stability below 90° and above 130° .

LOUISE KELLEY

The solubility of mercuric bromide in ethyl and methyl alcohols. K. L. MAL-

ROTRA. *J. Indian Chem. Soc.* **5**, 545-7(1928).— HgCl_2 of 99.76% purity was dissolved in $\text{C}_2\text{H}_5\text{OH}$ whose purity was 99.78%, in wet alc. 87.73% $\text{C}_2\text{H}_5\text{OH}$, and in 99.88% CH_3OH at several temps. for each solvent. The solubilities in g. per 100 g. of 99.76% $\text{C}_2\text{H}_5\text{OH}$, for the temps. indicated are: 0.0° , 24.04; 16.15° , 26.25; 24.95° , 28.40; 29.15° , 29.28; 31.35° , 30.05; 34.30° , 31.29; 41.60° , 33.53; 44.80° , 34.55; 48.60° , 35.87; 53.20° , 37.80; 58.00° , 39.80; 60.15° , 40.63; 64.80° , 43.10; 79.25° , 60.15. The solubilities of HgCl_2 in g. per 100 g. of 87.73% $\text{C}_2\text{H}_5\text{OH}$ at the temps. indicated are: 39.20° , 17.22; 42.13° , 21.44; 45.20° , 22.91; 49.07° , 25.35; 55.85° , 28.61; 61.60° , 31.84; 68.97° , 37.11. The solubilities of HgCl_2 in g. per 100 g. of 99.88% CH_3OH at the temps. indicated are: 22.10° , 67.62; 27.40° , 68.81; 30.80° , 70.25; 36.10° , 72.21; 40.90° , 84.43. When a satd. soln. of HgCl_2 in CH_3OH stands for a few hrs needle-like crystals form. The probable compn. of the crystals is $\text{HgBr}_2 \cdot \text{CH}_3\text{OH}$.

F. E. BROWN

Cryoscopic studies on the transition points of the compounds of organic solvents with salts. I. HAJIME OSAKA. Univ. Tokyo. *Bull. Chem. Soc. (Japan)* **3**, 289-97 (1928); cf. *C. A.* **23**, 20.—The lowering of the transition point at which $\text{NaI} \cdot 3\text{Me}_2\text{CO}$ loses Me_2CO by soln. of foreign substances was studied and the mol. depression referred to 100 g. Me_2CO found to be 24.0. The transition point was also detd. as 25.5° . The method may be regarded as cryoscopy with an artificially elevated m. p. and can be used practically for the detn. of mol. wts. A similar study was made with $\text{HgCl}_2 \cdot \text{Me}_2\text{CO}$. The mol. depression was found to be 24 and the transition point 20.7° . However, this system shows some inaccuracy so that it can hardly be applied in practical cryoscopy.

ALBERT L. HENNE

The significance of the relaxation time of the ionic atmosphere for the irreversible processes of electrical conduction in strong electrolytes. H. FALKENHAGEN AND J. W. WILLIAMS. *Z. physik. Chem.* **137**, 399-420(1928); cf. *C. A.* **22**, 3573.—In solns. of strong electrolytes there are on the av. more ions of unlike sign than of like sign about any particular ion. For this ionic atm. there are 2 characteristic quantities, its thickness $1/\kappa$, and its relaxation time θ . For the thermodynamics of strong electrolytes only κ is of significance, but for the irreversible processes of elec. cond. both κ and θ are important. The Wien effect is next discussed and it is shown that in a 0.0001 *M* soln. of KCl under a field strength of 100,000 v./cm., the ions move about twenty-five times the thickness of the ionic atmosphere in the time that it is necessary to build up the ionic atmosphere; hence the inter-ionic attractive forces between the ions no longer can exert their braking forces and the cond. of the soln. corresponds to that at infinite diln. The Wien effect can be partially calcd. (cf. *C. A.* **22**, 2861) theoretically by making several successive approximations. The agreement is of the right order of magnitude.

MALCOLM DOLF

Condition of iodic, hydrofluoric and chromic acids and their salts in aqueous solution. N. R. DHAR. *J. Indian Chem. Soc.* **5**, 585-92(1928).—An analysis of the data of others on elec. cond., lowering of f. p., elevation of b. p. and coagulation of $\text{Fe}(\text{OH})_3$ sols by iodic and hydrofluoric acids and their salts shows that the negative ion of iodic acid and iodates is $\text{I}_2\text{O}_6^{--}$ and of hydrofluoric acid and fluorides is F^- . The second disson. const. of H_2CrO_4 is about 5×10^{-8} . $\text{K}_2\text{Cr}_2\text{O}_7$ exists partly in soln. as KHCrO_4 (cf. *C. A.* **16**, 3274).

F. E. BROWN

The determination of the activity of one substance from that of another by a cell with a liquid junction. RALPH F. NIELSEN AND HERMAN A. LIEBHAFSKY. Univ. of Nebraska. *J. Am. Chem. Soc.* **51**, 223-4(1929).—It is pointed out that the measurements by Schuhmann (*C. A.* **18**, 615) on the cell $\text{H}_2, \text{HCl} (c) | \text{HClO}_4 (c)$, II, show that the activity coeff. of the H ion is substantially the same in HClO_4 as in HCl , up to a concn. of 1.1 molal, but do not prove that the mean activity coeff. of HClO_4 is the same as that of HCl .

E. R. SMITH

Solid solutions by precipitation. G. NATTA AND L. PASSERINI. Reale Politecnico, Milano. *Gazz. chim. ital.* **58**, 597-618(1928).—Expts. have already shown (cf. N. and Reina, *C. A.* **20**, 3399) that the simultaneous pptn. of 2 hydroxides is an easy way to obtain solid solns. The x-ray lines of such solns. were known to differ from those of the components, but it is only now with the development of a new app. and technic that it is possible to measure the lines quantitatively. With a chamber of special construction for measurements by the Laue powder method, the slight deformations in the lattice on substituting some atoms for others with only slightly different diams. could be detd. The precision of the method was better than 0.005 Å. U. An extensive series of expts. in which hydroxides, carbonates and sulfides were pptd., yielded solid solns. wherever it was theoretically possible to obtain them. The present paper deals with solid solns. prepd. by pptn. with alkalis from aq. solns. of Ni, Co, Mg,

Cd, Mn and Ca salts, the x-ray structure of the rhombohedral hydroxides and their solid solns. being detd. The following data give the lattice consts. (a , c , c/a and d , resp.) of the individual hydroxides, expressed in A. U.: $\text{Mg}(\text{OH})_2$, 3.11, 4.73, 1.52, 2.40; $\text{Ni}(\text{OH})_2$, 3.075, 4.61, 1.50, 4.09; $\text{Co}(\text{OH})_2$, 3.195, 4.66, 1.46, 3.75; $\text{Mn}(\text{OH})_2$, 3.34, 4.68, 1.40, 3.26; $\text{Cd}(\text{OH})_2$, 3.475, 4.71, 1.355, 4.92; $\text{Ca}(\text{OH})_2$, 3.32, 4.93, 1.40, 2.30. The systems: $\text{Ni}(\text{OH})_2$ - $\text{Co}(\text{OH})_2$, $\text{Ca}(\text{OH})_2$ - $\text{Cd}(\text{OH})_2$, $\text{Cd}(\text{OH})_2$ - $\text{Ni}(\text{OH})_2$, $\text{Mg}(\text{OH})_2$ - $\text{Co}(\text{OH})_2$, $\text{Mg}(\text{OH})_2$ - $\text{Ni}(\text{OH})_2$, $\text{Cd}(\text{OH})_2$ - $\text{Mn}(\text{OH})_2$, $\text{Zn}(\text{OH})_2$ - $\text{Mg}(\text{OH})_2$, $\text{Zn}(\text{OH})_2$ - $\text{Ni}(\text{OH})_2$ and $\text{Zn}(\text{OH})_2$ - $\text{Co}(\text{OH})_2$ were examd. Not all pairs of hydroxides of the rhombohedral series are capable of forming solid solns. even though they have the same cryst. form and similar elementary cells. Simultaneous pptn. results in solid solns. only with hydroxides whose cations have atomic radii not too different. Thus $\text{Mg}(\text{OH})_2$ forms solid solns. with $\text{Co}(\text{OH})_2$, $\text{Ni}(\text{OH})_2$ and $\text{Mn}(\text{OH})_2$, but not with $\text{Cd}(\text{OH})_2$ or $\text{Ca}(\text{OH})_2$. It also forms solid solns. with $\text{Zn}(\text{OH})_2$; in fact though $\text{Zn}(\text{OH})_2$ is generally considered rhombic, it forms solid solns. with a rhombohedral structure by pptn. with $\text{Mg}(\text{OH})_2$, $\text{Ni}(\text{OH})_2$ and $\text{Co}(\text{OH})_2$. The soly. of $\text{Zn}(\text{OH})_2$ in $\text{Mg}(\text{OH})_2$, $\text{Ni}(\text{OH})_2$ and $\text{Co}(\text{OH})_2$ should not be attributed to a polymorphism of $\text{Zn}(\text{OH})_2$, which has not been proved exptly., but rather to the great similarity in the dimensions of the Zn ion and the ions of Mg, Ni and Co. As has been observed already in other types of compds., the chief (if not the only) cause of isomorphism in the hydroxide series lies in the dimensions of the isomorphous groups. The similarity in the dimensions of the Zn, Mg, Co, Ni and ferrous ions allows a miscibility in the solid state. In all cases of solid solns., there was a very great regularity in the variations of the lattice consts. and relative intensities of the lines of the x-ray photographs, and in no case was there observed the formation of solid solns. with regular distribution of atoms of the type assumed by Tammann. The axial ratios, the vol. of the elementary cell and the d were always intermediate between those of the components, and conformed to the calcd. values based on a linear function of the compn. The law of Vegard was thus followed. The following data are for solid solns. contg. 50% of the components, and give the values of a , c , c/a and d (in A. U.), resp.: $(\text{Mg}, \text{Co})(\text{OH})_2$, 3.15, 4.66, 1.48, 3.11; $(\text{Mg}, \text{Ni})(\text{OH})_2$, 3.09, 4.67, 1.51, 3.242; $(\text{Co}, \text{Ni})(\text{OH})_2$, 3.13, 4.63, 1.48, 3.92; $(\text{Ca}, \text{Cd})(\text{OH})_2$, 3.50, 4.83, 1.38, 3.57; $(\text{Mg}, \text{Cd})(\text{OH})_2$, 3.40, 4.655, 1.37, 4.28; and the following data the same consts. for solns. contg. 25-35% $\text{Zn}(\text{OH})_2$: $(\text{Zn}, \text{Mg})(\text{OH})_2$, 3.09, 4.76, 1.54, 2.98; $(\text{Zn}, \text{Ni})(\text{OH})_2$, 3.04, 4.62, 1.52, 4.268; $(\text{Zn}, \text{Co})(\text{OH})_2$, 3.15, 4.66, 1.48, 3.948. By assuming that solid solns. of $\text{Zn}(\text{OH})_2$ follow, as do the others, the law of Vegard, calens. show for a hypothetical rhombohedral modification of $\text{Zn}(\text{OH})_2$ an elementary cell with a dimension around 3.03 A. U. and an axial ratio around 1.60.

C. C. DAVIS

Importance of crystalline form in the formation of solid solutions. II. Thermal analysis of the system lithium chloride-cadmium chloride. A. FERRARI AND A. BARONI. *Atti accad. Lincei* 7, 1040-3(1928); cf. C. A. 23, 744. The chlorides of Mg, Li, Co, Ni⁺⁺, Fe⁺⁺, Mn⁺⁺ and Cd all form crystals whose structures are very similar and, therefore, might be expected to form double salts. The m. ps. of mixts. of LiCl and CdCl_2 were detd. and the equil. curves showed the existence of the compds. $3\text{CdCl}_2 \cdot 4\text{LiCl}$, m. 522° and $3\text{CdCl}_2 \cdot 2\text{LiCl}$, m. 516°.

% CdCl_2	M. p.	Mol. % CdCl_2	M. p.	Mol. % CdCl_2	M. p.
0%	603°	52.0%	506°	75.2%	516°

III. Thermal analysis of the systems: manganese chloride-cobalt chloride; cadmium chloride-cobalt chloride and magnesium chloride-cobalt chloride (anhydrous). A. FERRARI AND A. INGANNI. *Ibid* 8, 238-43(1928).—The equil. curves for the m. ps. of mixts. of MnCl_2 and CoCl_2 , of CdCl_2 and CoCl_2 and of MgCl_2 and CoCl_2 are shown. The curves are perfectly smooth with no max., min., or eutectic points, showing complete miscibility in the solid state for these systems. Thus complete miscibility with similarity of crystal form is shown. IV. The thermal analysis of the systems: magnesium chloride-iron chloride and cadmium chloride-iron chloride (anhydrous). *Ibid* 306-9.—The equil. curves here also are smooth, the m. ps. of all mixts. being

by H ions of an heterogeneous reaction like the hydrolysis of cotton cellulose in solns. of HCl, both alone and in the presence of KCl, NaCl or LiCl. With dil. acid solns. the ultimate product of the hydrolysis is hydroxycellulose, and under such conditions there is a linear relation between the rate of hydrolysis and the H-ion activity of the soln. In strongly acid solns., velocity measurements are untrustworthy, because of the tendency of the hydrocellulose to hydrolyze further. The linear relationship between H-ion activity and rate of hydrolysis does not hold in acid-salt solns. Over the range of concns. examd., the velocity of reaction is higher in a soln. contg. both acid and salt than in an acid soln. of the same H-ion activity but without the salt. It is suggested that the added salt lowers the activity coeff. of the "critical complex" [(cellulose) $\text{H}^+\cdot\text{H}_2\text{O}$].

ALBERT L. HENNE

Influence of a magnetic field on the reaction velocity of gases. GERTRUD KORN FELD. Univ. Berlin. *Naturwissenschaften* 16, 1029(1928).—Contrary to the results in a previous note (C. A. 19, 3207), it is now concluded that the reaction $2\text{NO}_2 = \text{O}_2 + \text{NO}$ is not influenced by a magnetic field.

B. J. C. VAN DER HOEVEN

Kinetic studies of ethylene oxides. J. N. BRØNSTED, MARY KILPATRICK AND MARTIN KILPATRICK. Polytech. Inst., Copenhagen. *J. Am. Chem. Soc.* 51, 428-61 (1929).—The ethylene oxides react in aq. solns. in 4 different ways. (1) They unite spontaneously with H_2O to form glycols. (2) The same reaction proceeds, catalyzed by H ions (H_3O^+). (3) They react with anions and H_2O taking up acid. (4) They add acids directly. These reactions were studied separately for ethylene oxide, glycid and epichlorohydrin. (1) and (2) were measured dilatometrically. A special titrimetric procedure in artificially controlled buffers was devised for measuring (3). (4) was measured by elec. cond. The ethylene oxides exhibit apparently basic properties in certain solns. They are, however, not bases or pseudo-bases. Their "basicity" is due to their addition acids (reactions (3) or (4)). The oxides may also add bases and thus appear as acids. The rate of reaction (2) is detd. by the concn. of the H ion. There is considerable positive primary salt effect, which is linear in character. The velocity of reaction (3) is proportional to the anion concn., and shows slight negative primary salt effect. The velocity const. increases in the order Cl^- , Br^- , CSN^- , I^- and in the order formate, benzoate, acetate, trimethylacetate ion. The direct addn. of strong acid (reaction (4)) was studied with glycid and HBr. The velocity followed the theoretical equation for such reactions, exhibiting an exponential negative salt effect of the predicted magnitude. The velocity consts. k_1 , k_2 , k_3 and k_4 for reactions (1), (2), (3) and (4) are approx. related by the equation $k_1/k_2 = k_3/k_4$. R. L. D.

Free energy of formation of fused alkaline hydroxides. GIOVANNI DEVOTO. Reale Univ. Milano. *Gazz. chim. ital.* 58, 450-7(1928); cf. C. A. 23, 558. The decompn. potentials of fused alk. hydroxides measured by earlier investigators (cf. *Z. anorg. allgem. Chem.* 28, 385(1901); *Z. Elektrochem.* 8, 697, 817, 939(1902); Neumann and Bergve, C. A. 10, 556; Mazza, *Atti II congresso naz. chim. pura applicata* 1926, 719) are limited in their temp. range, so further measurements were made at other temps. and with better app., the latter being that used by Cambi and D (cf. C. A. 22, 1716), with Ni electrodes. The results, which are for the *polarization potentials of NaOH from 342° to 804°, of KOH from 370° to 710° and of LiOH from 475° to 712°*, are given in tabular and graphical form. The values are much higher than those obtained by the discharge-potential method. With the intensity applied to the system, the Jahn formula (cf. *Z. physik. Chem.* 16, 45(1895)) did not apply, a const. state of saturation being reached. Depolymerization occurred only with LiOH, with no supertension at the temps. used, so that the potentials of polarization and of formation were identical. This allowed the use of the Gibbs-Helmholtz law, with the aid of which the entropy could be calcd. The following data give the affinity in calories for NaOH and KOH, resp., at the particular temps.: 400°, 53,620, 52,720; 500°, 50,330, 49,470; 600°, 47,420, 46,190; 700°, 43,350, 40,650.

C. C. DAVIS

Catalysis with metals of the platinum group. G. R. LEVI. *Atti accad. Lincei* 8, 409-14(1928).—The catalytic effect on the rate of the reaction $\text{SO}_2 \xrightarrow{\text{Pt}} \text{SO}$ and Pt-group alloys was studied. The alloys were Pt + 10% of other Pt-group metal. The order of increasing effectiveness was Pt-Ir, Pt-Rh, Pt-Pd, Pt, Pt-Ru, Pt-Os. X ray studies indicated that particle size, i. e., the phys. properties of the catalyst, does not det. the efficiency as a catalyst.

A. W. CONTIERI

Poisoning effect of certain substances on the iron catalyzer in the decomposition of carbon monoxide. TOKUNOSUKE WATANABE. *Bull. Inst. Phys. Chem. Research* (Tokyo) 7, 1078-87(1928); *Abstracts* 1, 102-3.—CO from formic acid is decompd. in an iron pipe on iron gauze, and the resulting gas is analyzed. The effects of H_2O ,

N, H, CH_4 , C_2H_2 , C_6H_6 , C_8H_8 , H_2S and $\text{C}_4\text{H}_4\text{S}$ on the catalysis are investigated. N, CH_4 , C_6H_6 and C_2H_2 have no effect, except that C_2H_2 liberates C. H_2O gives some CO_2 , H_2 and CH_4 . H gives CH_4 . Naphthalene causes a progressive drop in the catalysis efficiency, but the fall is temporary; by passing pure CO over the poisoned catalyst, the initial efficiency is recovered. S compds. kill the catalyst. A. L. H.

The autoxidation of benzaldehyde. RICHARD KUHN AND KARL MEYER. Eidgen. Tech. Hochschule, Zürich. *Naturwissenschaften* 16, 1028-9(1928).—By repeated vacuum distn. in CO_2 and fractional crystn. with liquid air BzH was prepd. of such purity that it did not show any autoxidation in air. Small addns. of Fe, Cu, Ni or Mn salts accelerate the oxidation considerably, 1 mol. FeCl_3 per 1200 mols. BzH being sufficient to cause the oxidation of half of it into BzOH in 40 min. contact with air at 20° . HCN and $\text{H}_4\text{P}_2\text{O}_7$ inhibit this catalysis. Ferrous salt is 15 times more active than ferric salt (BzH in C_6H_6 soln. shaken with aq. catalyzer soln.). The rate of the catalysis by ferric salt increases rapidly after an induction period, the BzH layer turns orange-brown and the aq. layer becomes colorless. Ferrous salt gives this orange coloration immediately. Fifty times more active than ferrous salt is hemin iron; the difference between phosphate hemin and pyridine hemin is notable, the former being completely inactive. B. J. C. VAN DER HOEVEN

Autoxidation and anti-oxygen action. The catalytic properties of arsenic and its compounds. CHARLES MOURKEU, CHARLES DUFRAISSE AND MARIUS BADOCHÉ. *Compt. rend.* 187, 917-21(1928).—The catalytic autoxidative properties of 22 substances were examd. A distinct anti-oxygen action with benzoic aldehyde is shown by As. With turpentine oxidation is first accelerated and then retarded. As_2O_3 retards the oxidation of Na_2SO_3 , and is an anti-oxygen in the case of furfurole, while its effect is not so marked with benzoic aldehyde. The org. oxygen compds. of As are in general more active than the inorg. compds., while the halogen compds. of As are more active than either. L. T. FAIRHALL

The system: Aluminum chloride-potassium chloride-hydrochloric acid-water between 0° and 80° . G. MALQUORI. Reale Univ., Roma. *Gazz. chim. ital.* 58, 562-8 (1928). The possibility of sepg. AlCl_3 and KCl from the soln. from the attack of leucite by the Blanc process (cf. C. A. 19, 1616) depends upon the variations of the soly of the 2 salts with temp. and acidity. For this reason the polythermic diagram of the system AlCl_3 -KCl-HCl- H_2O was constructed for the temp. range of 0 - 80° . Most of the data essential to this have already been published (cf. C. A. 22, 529, 3852), the other necessary data being obtained by further expts. The isotherms show that the only solids in contact with satd. solns. under any of the conditions studied were KCl and $\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$. With these data and the diagrams constructed from the various isotherms it was possible to establish the compn. of a soln.: $x\text{A} + y\text{B} + z\text{C} + \text{H}_2\text{O} = 100$ which is satd. with respect to C and having a const. ratio $(x\text{A})/(y\text{B})$, when it is assumed that the satn. curves for different contents of B are similar to those of the ternary system: A-C- H_2O . For the construction of the polythermic diagram, a triangular prism was used, the projection of which on the KCl- AlCl_3 face, and therefore on the vertical plane, is reproduced. The vertices of the triangular base of the prism indicate the 3 components of the solute, viz., KCl, AlCl_3 and HCl, while the altitude represents temps. In the interior of the prism are traced the isotherms for different temps. The superposition of the isotherms forms the surface, every point of which represents the relations of KCl, AlCl_3 and HCl for solns. satd. with respect to the 2 salts. To include the H_2O , the 2-dimensional method of Lodochnikov (cf. C. A. 20, 1939; 22, 2101) was utilized. The resulting diagram, with the surface of the satd. quaternary solns. of the 2 salts within, allows the detn. of the compn. of a soln. with any % HCl. C. C. DAVIS

Heat of combustion and of solution of dihydroxyacetone. MARIA KOBEL AND WALTHER A. ROTH. Kaiser Wilhelm-Inst. für Biochemie, Berlin-Dahlem. *Biochem. Z.* 203, 159-63(1928).—Freshly prepd. dihydroxyacetone yields 343.1 kg. cal. per mol. upon complete oxidation. The heat of combustion of 2 mols. dihydroxyacetone is 12-16 kg. cal. greater than the molar combustion heat of known hexoses. The heat of soln. is 3.98 kg. cal. per mol. The temp. change during soln. indicates that the substance undergoes a transformation in the soln. which follows a monomol. course. S. MOROULIS

A thermal effect described by Q. Majorana. A. L. TH. MOESVELD. Univ. Utrecht. *Chem. Weekblad* 25, 702-3(1928).—The effect described by Majorana (C. A. 21, 851) of self-heating of metals after previous chilling is attributed here to establishment of equil. in a metastable system. The order of magnitude of the heat effect (12 cal. per day) is correct as expected for a slow transition. The explanation by air absorption (Schirmann, *Physik. Z.* 29, 676(1928)) is less probable. B. J. C. v. d. H.

by H ions of an heterogeneous reaction like the hydrolysis of cotton cellulose in solns. of HCl, both alone and in the presence of KCl, NaCl or LiCl. With dil. acid solns. the ultimate product of the hydrolysis is hydroxycellulose, and under such conditions there is a linear relation between the rate of hydrolysis and the H-ion activity of the soln. In strongly acid solns., velocity measurements are untrustworthy, because of the tendency of the hydrocellulose to hydrolyze further. The linear relationship between H-ion activity and rate of hydrolysis does not hold in acid-salt solns. Over the range of concns. examd., the velocity of reaction is higher in a soln. contg. both acid and salt than in an acid soln. of the same H-ion activity but without the salt. It is suggested that the added salt lowers the activity coeff. of the "critical complex" [(cellulose) H⁺, H₂O].

To include the H_2O , the 2-dimensional method of Lodochnikov (cf. C. A. 20, 1939; 22, 2101) was utilized. The resulting diagram, with the surface of the satd. quaternary solns. of the 2 salts within, allows the detn. of the compn. of a soln. with any % HCl. C. C. DAVIS

Heat of combustion and of solution of dihydroxyacetone. MARIA KOBEL AND WALTHER A. ROTH. Kaiser Wilhelm-Inst. für Biochemie, Berlin-Dahlem. *Biochem. Z.* 203, 159-63(1928).—Freshly prepd. dihydroxyacetone yields 343.1 kg. cal. per mol. upon complete oxidation. The heat of combustion of 2 mols. dihydroxyacetone is 12-16 kg. cal. greater than the molar combustion heat of known hexoses. The heat of soln. is 398 kg. cal. per mol. The temp. change during soln. indicates that the substance undergoes a transformation in the soln. which follows a monomol. course. S. MORGULIS

A thermal effect described by Q. Majorana. A. L. TH. MOESVELD. Univ. Utrecht. *Chem. Weekblad* 25, 702-3(1928).—The effect described by Majorana (C. A. 21, 851) of self-heating of metals after previous chilling is attributed here to establishment of equil. in a metastable system. The order of magnitude of the heat effect (12 cal. per day) is correct as expected for a slow transition. The explanation by air absorption (Schirmann, *Physik. Z.* 29, 676(1928)) is less probable. B. J. C. v. d. H.

The determination of the heat of dilution of potassium chloride solutions at infinite dilution. E. LANGE AND P. A. LEIGHTON. *Z. Elektrochem.* **34**, 566-71(1928).—Improvements in the differential adiabatic calorimeter make possible measuring calorimeter temps. to 0.0000005°. The heats of diln. of KCl solns. were measured down to 0.0005 *M*. In very dil. solns. heats of diln. are proportional to ionic strength. The factor of proportionality agrees at 25° within exptl. error with that calcd. from Debye's equation. At 12° agreement is not so close. F. R. BICHOWSKY

Heat capacities in aqueous salt solutions. MERLE RANDALL AND FREDERICK D. ROSSINI. Univ. Cal. *J. Am. Chem. Soc.* **51**, 323-45(1929).—A calorimeter is described for measuring differentially the heat capacities of aq. salt solns. with a precision greater than 0.1 per 1000. Methods of calibrating and operating for direct and for differential heat-capacity measurements are also described. Methods of detg. and calcg. the apparent molal heat capacity of the solute, the partial molal heat capacities of the solute and solvent, and the sp. heat of the soln. are given. Data are reported for the nitrates, chlorides, bromides, iodides and sulfates of Na and K in aq. soln. from 1.0 or 2.5 *M* to infinite diln. A theoretical equation based on the Debye-Hückel theory is derived for the molal heat capacities of the solute which agrees well with the exptl. data. The partial molal heat capacity of an ion depends upon its charge, size and configuration. The partial molal heat capacities of ions are shown to be additive at infinite diln. The bearing of the data upon the hydration of ions and on the temp. coeff. of the heat of soln. of a strong electrolyte in a large amt. of H₂O is discussed. J. H. PERRY

The metastability of elements and compounds as a consequence of enantiotropy and monotropy. XII. Heats of solution. I. ERNST COHEN AND J. KOOP. *Z. physik. Chem., Abt. A*, **139**, 273-350(1928); cf. *C. A.* **23**, 555.—The literature indicates that the heat of soln. of some salts depends on their thermal history. Cohen and Koop confirm this and explain it on the basis of the formation of metastable mixts. of allotropic forms. An adiabatic elec. calorimeter of the type described by Cohen (*C. A.* **19**, 1509) was used. The following observations are reported: (a) K_2SO_4 occurs in two modifications. The heat of soln. at 20.0° of $\alpha K_2SO_4 \rightarrow K_2SO_4 \cdot 400H_2O$ is -6284 ± 4 cal. If the salt has been heated above the transition point the heat of soln. deviates from the above value, the amt. of deviation depending upon the rate of cooling. K_2SO_4 which has been melted and gives a neutral reaction shows this deviation. If the salt has an alk. reaction after melting a large deviation due to the influence of alkali on the change αK_2SO_4 to βK_2SO_4 appears. On standing, spontaneous change to the stable form occurs. (b) KNO_3 shows enantiotropy. The heat of soln. at 20.0° for the stable $\alpha KNO_3 \rightarrow KNO_3 \cdot 200H_2O$ is -8336 ± 2 cal. At 20.5° the heat effect for $\alpha KNO_3 \rightarrow KNO_3 \cdot 350H_2O$ is -8426 ± 2 cal. If the salt is heated above its transition point a deviation in the heat effect appears which vanishes on standing. (c) Tl_2SO_4 has been reported previously only in the rhombic modification. The heat of soln. for $Tl_2SO_4 \rightarrow Tl_2SO_4 \cdot 300H_2O$ at 20.0° is -7940 ± 60 cal. When crystd. in the cold from water or pyridine-water mixts, when melted and quenched or when melted and cooled slowly, the salt has the same heat of soln. as when crystd. from water and heated to 170°. If the water soln. is pptd. with MeOH or EtOH the product shows a deviation. On heating to 160° this deviation disappears. (d) $KCl \rightarrow KCl \cdot 200H_2O$ shows the following heat effects: at 20.0° -4373 ± 2 cal.; at 25° -4191 ± 2 cal. These values are independent of the thermal history. (e) For $NaCl \rightarrow NaCl \cdot 100H_2O$ they found at 20.0° a value of -1100 ± 4 cal. and at 25.0° -965 ± 2 cal. No deviations due to thermal history were observed. J. B. AUSTIN

Influence of x-rays on the structure of bismuth and tellurium. III. E. ADINOLFI. *Atti accad. Lincei* **8**, 381-8(1928); cf. *C. A.* **19**, 3216. —The sp. heat of Bi and Te is increased 5.2% and 4.8%, resp., by chilling the fused metals. By exposing these metals to x-rays the sp. heats are increased 11% for Bi, and 14% for Te, indicating that changes in crystal structure have occurred in both cases. A. W. CONTIERI

The heats of formation of the double chlorides of cadmium and potassium. AGOSTINI. *Atti accad. Lincei* **8**, 393-4(1928).—The heats of formation of the two known double salts $KCl \cdot CdCl_2$ (m. = 431°); and $4KCl \cdot CdCl_2$ (m. = 461°) were measured. $KCl \cdot CdCl_2$: the reaction $KCl \cdot CdCl_2 + 2KOH$ aq. = $3KCl$ aq. + $Cd(OH)_2 \downarrow + Q$ where Q = sum of heat of dissocn. of the double salt + heat of pptn. of a mol. of $Cd(OH)_2$. Subtracting these two values $(+2.01) - (+5.66) = -3.65$, or $+3.65$ as the desired heat of formation. $4KCl \cdot CdCl_2$: The heat of pptn. gave $Q = +4.67$ so that heat of pptn. is $+4.67 - 5.66 = -0.99$ or heat of formation = $+0.99$, which agrees with the fact that this is a very unstable salt. A. W. CONTIERI

Heats of formation of the double chlorides of copper and potassium. P. AGOSTINI. *Atti accad. Lincei* 7, 1030-2(1928).—As the salts $\text{CuCl}_2 \cdot 2\text{KCl}$ and $\text{CuCl}_2 \cdot \text{KCl}$ on soln. dissociate into the component salts, the heats of formations are measured by the heat of soln. minus the heats of soln. of KCl and CuCl_2 . $\text{K}_2\text{CuCl}_4 = 2\text{KCl} + \text{CuCl}_2 + -4.09 \text{ cal.}$ and $\text{KCuCl}_3 = \text{KCl} + \text{CuCl}_2 - 4.59$, the heats of formation are therefore, +4.09 and +4.59 cal.

A. W. CONTIERI

Heats of formation and hydration of the double salts of cobalt and potassium and of copper and sodium. F. DE CARLI. *Atti accad. Lincei* 7, 1033-6(1928).—The heat of formation of $\text{K}_2\text{CO}_3 \cdot \text{CoCO}_3$ was detd. from the reaction $\text{K}_2\text{CO}_3 \cdot \text{CoCO}_3 + 4\text{HCl aq.} = 2\text{KCl aq.} + \text{CoCl}_2 \text{ aq.} + 2\text{CO}_2 + 2\text{H}_2\text{O}$. 460.17 is the heat of formation of the component salts + heat of combination $\text{K}_2\text{CO}_3 \text{ soln.} + \text{CoCO}_3 \text{ ppt.}$; so that the heat of addition = +5.76 cal. and the heat of hydration = +11.37 cal. Similarly the heat of formation of the double salt $\text{Na}_2\text{CO}_3 \cdot \text{CuCO}_3 = +10.33 \text{ cal.}$, and its heat of hydration ($3\text{H}_2\text{O}$) = +9.296 cal.

A. W. CONTIERI

Oxide cells of cadmium, copper, tin and lead. CHARLES G. MAIER. Bureau of Mines. *J. Am. Chem. Soc.* 51, 194-207(1929).—Oxide electrodes of Cd , Cu^I , Cu^{II} , Sn^{II} , Sn^{IV} and Pb^{IV} were compared to the H or HgO electrode in solns. of Ba(OH)_2 . Free energies of formation and heats of formation calcd. from the results are summarized in the following table.

Substance	ΔF°_{298} of formation (cal)	ΔH_{298} of formation from cell coeff.
CdO	-55,064 \pm 500	-62,305 \pm 500
Cd(OH)_2	-112,178 \pm 500	-131,850 \pm 500
Cu_2O	-34,672 \pm 200	-38,400 \pm 2000
CuO	-30,800 \pm 200	-38,652 \pm 1000
SnO	-61,332 \pm 300	-80,000 \pm 15000
SnO_2	-123,200 \pm 400

3—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

S. C. LIND

Address of the President (High-frequency radiation). ERNEST RUTHERFORD. *Proc. Roy. Soc. (London)* B104, 97-119(1929).—Recent developments in the production and study of high-frequency radiations of the x-ray type are discussed.

Temperature radiation of the fixed stars. A. BRILL. *Z. Physik* 52, 767-95 (1928).—Discussion and critique of existing data. JOSEPH S. HEPBURN

Does a universal relation exist between the electron charge e and the Planck quantum h ? JOSEF PERLES. *Naturwissenschaften* 16, 1094-5(1928).—Between h and e an arbitrary numerical relation $h = [1/(\pi - 1)](m_P/m_E)(c^2/c)$ is shown to exist, m_P and m_E being proton and electron masses. GEORGE GLOCKLER

A pragmatic system of notation for electronic valence conceptions in chemical formulas. HARRY SHIPLEY FRY. Univ. of Cincinnati. *Chem. Reviews* 5, 557-69 (1928).—Pragmatic chemists are more vitally concerned with the adoption of a system of electronic valence notation which is primarily designed to indicate and correlate the actual chem. behavior of the atoms and the radicals of the mol. as displayed under specific exptl. conditions than with the imposition upon structural formulas of an electronic system of notation which is complicated by metaphysical speculation involving the unsolved problems of the constitution of the atom and the disposition of the hypothetical electron shells or the elusive electron orbits of its valence electrons. B. J. C. VAN DER HOEVEN

Degrees of freedom in wave mechanics. V. S. VRKLIJAN. *Z. Physik* 52, 735-8 (1928).—Two problems (H atom with and without motion of the nucleus) are treated with fewer degrees of freedom than are actually present and the correct results are obtained. ALBERT L. HENNE

The scattering power of a bare nucleus according to wave mechanics. G. TEMPLE. Imperial College. *Proc. Roy. Soc. (London)* A121, 673-5(1928).—In parabolic coordinates the wave equation solution for scattering from a nucleus is much simplified. The result is the same as in the classical mechanics. GEORGE GLOCKLER

Test of Schroedinger's theory. II. J. L. SNORK, JR. *Z. Physik* 52, 654-6 (1928).—The previously mentioned (*C. A.* 23, 26) measurements on the absorption of $H\alpha$ and $H\beta$ are repeated under different conditions. Similarly the ratio of $H\beta$ to $H\gamma$ is detd. The values found for the ratio of total absorption and for the double ratio of the doublet components are in satisfactory agreement with the theory. F. R. BICHOWSKY

Quantum mechanics of electrons in crystals. F. BLOCH. *Z. Physik* 52, 555-99 (1928).—The motion of an electron in a crystal lattice is studied on the basis of wave mechanics. By the use of Fermi statistics it is possible to make deductions regarding the part of the sp. heat of a crystal due to the electrons. If the thermal vibrations of the lattice are taken into account, then qualitatively order of magnitude and temp. dependence of elec. cond. can be detd. in agreement with expt. GEORGE GLOCKLER

Davisson-Germer effect (scattering of electrons by crystals). K. SHAPOSHNIKOV. Iwanowo-Wosnessensk. *Z. Physik* 52, 451-2(1928); cf. *C. A.* 21, 1927; 22, 350, 538, 4354.—The effect is explained on the basis of a mechanical light quantum hypothesis. GEORGE GLOCKLER

A symmetrical treatment of the wave equation. A. S. EDDINGTON. *Proc. Roy. Soc. (London)* A121, 524-42(1928).—Dirac's formulation of dynamics gives unsymmetrical matrices, and transformation equations not of tensor form. By picking out a proper set of symmetrical matrices, the same wave equation is derived (to first order) the formulation of spin conditions becomes less artificial and derivation of the two-electron wave equation is simplified. F. R. BICHOWSKY

The generalized dispersion formula. IVAR WALLER. *Z. Physik* 51, 213-31 (1928); cf. *C. A.* 22, 912.—W. derives from wave mechanics and from classical quantum statistics equations for the scattering of x-rays by many-electron systems. The results

are worked out for both the scattering due to the fixed atom and that due to thermal motion.

Valence electrons of silver. J. M. ADAMS. *Z. Physik* 52, 882(1928).—Referring to Rosenfeld and Witmer on photoelec. work function (*C. A.* 22, 3577), A. points out that Ag may be thought of as having 3 valence electrons per atom since compds. of trivalent Ag are known.

F. R. BICHOWSKY

Stability of silver nucleus. J. KAPLAN. *Z. Physik* 52, 883(1928); cf. preceding abstract.—The 10 4d electrons of Ag must form a group of great stability, since Ag is usually univalent and its spectra are alkali-like. However, its crystal lattice must have 3 free electrons and hence the 4d shell has not the stability of the rare-gas shells.

GEORGE GLOCKLER

Rutherford satellite theory. G. SENTILE. *Atti accad. Lincei* [vi], 7, 346-9 (1928).—Arguments are advanced to show that nuclear systems discussed in Rutherford's theory are unstable and that the theory is therefore invalidated.

B. C. A.

Quantum theory of the nucleus. M. v. LAUR. *Z. Physik* 52, 726-34(1928).—The theory of radioactivity of the nucleus proposed by Gamov (*Ibid.* 51, 204(1928)) is discussed and certain mathematical steps in the derivation are corrected. A phys. significance is assigned to the two const. of the Geiger-Nuttall relation.

G. G.

Quantum theory of nuclear disintegration. G. GAMOV. Inst. for Theoretical Physics, Copenhagen. *Nature* 122, 805-6(1928).—In the nuclear model adopted, the region of inverse-sq.-law forces extends from without inwards to a crit. distance r_0 , which is appreciably less than the classical value for the closest approach of α -particles at which inverse-sq. scattering at large angles is still observed. Within r_0 the attractive forces vary very rapidly with distance. While the potential barrier at r_0 would maintain a classical α -particle for an infinite time within the nucleus, it cannot prevent the gradual leaking out of waves which represent the escape of α -particles on the wave theory. The theory gives the Geiger-Nuttall relation between the decay const. and the velocity of the α -particle. The same model allows the calcn. of the upper limit of the probability of nuclear disintegration by α -particles, on the assumption that disintegration takes place only if the α -particle penetrates within the potential barrier. The curves representing the probability of such penetrations plotting no. particles against the atom. no. of the element bombarded fall steeply to zero with large atomic nos. and are in satisfactory agreement with Rutherford's observation of no disintegration of atoms heavier than P, but at variance with the observations of Pettersson and Kirsch.

W. WEST

The application of Geiger's point counter in experiments on atom disintegration. NORBERT KREIDL. Inst. f. Radiumforschung, Wien. *Sitzb. Akad. Wiss. Wien, Abt. IIA*, 136, 589-602(1927).—The Greinacher method was used (*C. A.* 20, 2116) with acoustic or visual observation of the impacts. For measuring chamber the usual cylindrical one (2 cm. diam.) brass tube was used with the tip on one end and a brass shield at the other end, 1200 to 1900 v. being used. As the action of the point was limited to a radius of 3 mm. around it, efforts were made to use a knife edge instead of a point, no satisfactory results were obtained. Difficulties in differentiation of α - and β - (also γ - and H-) rays were experienced. Other methods, retrograde observation, etc., were tried out. On Po radiation the method gave too high results owing to Ra E radiation. It is concluded that a counting chamber without point is preferable for this type of work.

B. J. C. VAN DER HORVEN

Radium in rocks. I. Radium content of some representative granites of the eastern seaboard of the United States. CHARLES S. PIGGOT. Carnegie Inst., Washington. *Am. J. Sci.* 17, 13-34(1929).—A weighed amt. of pulverized rock was decomd. in a stream of pure dry CO_2 gas by fusion with mixed Na and K carbonates. The gases were scrubbed by an aq. soln. of 1 NaOH:3.5 aq., passed over stick NaOH and collected over Hg. Rn was detd. by an emanation electroscope. The granites examined and their respective Ra contents were (all $\times 10^{-12}$ g. per g. rock), Stone Mountain, Georgia (muscovite), 4.826; Mt. Airy, N. C. (biotite), 0.655; Woodstock, Md. (biotite diorite, with epidote), 1.448; Milford, Mass. (pink mottled biotite), 0.378; Rockport, Mass. (hornblende biotite), 0.955; Hurricane Island, Maine (biotite), 3.74. The analyses for these rocks are given. The Ra content is considered to be associated with minerals of high sp. gr. and particularly with the interstices between and the surfaces of grains. Part of the radioactivity can be extd. by hot water.

S. L. B. E.

Analysis of a radioactive pyromorphite from Gennammari (Sardinia). P. MISCIATELLI. *Atti accad. Lincei* 7, 929-32(1928).—A radioactive pyromorphite having the compn PbO 80.243, P_2O_5 14.640, Cl 2.4, As_2O_3 trace, SiO_2 1.06%, Sn and Sb traces, as well as traces of rare earths, was found to deflect an electroscope equiv. to the de-

Analysis of a radioactive pyromorphite from Gennammari (Sardinia). P. MISCIANTILLI. *Atti accad. Lincei* 7, 929-32(1928).—A radioactive pyromorphite having the compn. PbO 80.243, P_2O_5 14.640, Cl 2.4, As_2O_3 trace, SiO_2 1.06%, Sn and Sb traces, as well as traces of rare earths, was found to deflect an electroscope equiv. to the de-

flexion of 0.0028 g. U oxide. However, U was not found present, nor was Th. The activity must be derived from traces of Ra present in radioactive waters in the vicinity. A similar incident was first noted by Danne in 1905 (*Compt. rend.* 140, 241(1905)).

A. W. CONTIERI

The long-range α -particles of radium C. K. PHILIPP AND K. DONAT. *Z. Physik* 52, 759-66(1928); cf. *C. A.* 20, 3380.—The former app. is improved by taking stereoscopic pictures of the Wilson cloud chamber tracks with an ordinary motion-picture film. In 3000 pictures there are formed 221 long-range tracks. These fall into two groups of 9- and 11-cm. range. A very few α -particles of even longer range were observed. Out of 10^6 normal α -particles there are 29 of range 9.2 cm., 4 of range 11 cm. and 0.5 of even greater range.

GEORGE GLOCKLER

Ionization curve of α -rays from polonium in pure oxygen. TADASHI ONODA. *J. phys. radium* 9, 185-6(1928).—O was prepd. by electrolyzing NaOH soln. between Ni electrodes and purified by passing over red-hot Pd, through concd. H_2SO_4 and over $CaCl_2$ and P_2O_5 . Po was deposited upon a plate of Ni from a soln. of Po slightly acid with HCl. The ionization curve for air corresponded to the one measured by Mme. Curie. The ionization curve for O is given. Tracing a tangent from the point of inflection in the terminal portion of the curve which has a steep slope to the intersection with the abscissa gives a range of 3.63 ± 0.01 cm. at 15° 160 mm. and 3.49 ± 0.01 cm. at 0° 760 mm. From the ionization curve for air, the range is found to be 3.87 ± 0.01 cm. at 15° 760 mm. The stopping power for O is $3.87 \div 3.63 = 1.066 \pm 0.01$. This accords with the value of Gibson and Eyring.

FRANK MARESH

The β -ray spectrum of radiothorium. L. MEITNER. *Z. Physik* 52, 637-44 (1928).—The β -ray spectrum of Rd-Th taken in a magnetic field shows six lines. Four of these come from the L and M levels and are produced by two γ -rays whose energies exactly correspond to the energies of the α lines of the reaction product. This would mean that the α -particles of Rd-Th excite the K radiation of the decompn. product. The difficulties of such a view are discussed.

GEORGE GLOCKLER

New method for the determination of the direction of γ -rays. WERNER KOLHÖRSTER. *Naturwissenschaften* 16, 1044-5(1928).—Two Geiger counters register occasional simultaneous current impulses due to effects from the same secondary electron. In hard γ -radiation the secondary electrons will follow the directions of the γ -ray and by counting of the no. of coincidences in the 2 Geiger instruments locating them in various relative spatial directions, the direction of the γ -ray can be found. For 10 cm. Pb armor 3 times as many coincidences were found in the vertical as in the horizontal direction, in consequence of cosmic radiation. B. J. C. VAN DER HOEVEN

New method for absorption measurements of secondary β -rays. W. BOTHE AND W. KOLHÖRSTER. *Phys. tech. Reichsanstalt, Berlin-Charlottenburg. Naturwissenschaften* 16, 1045(1928).—Placing an absorbing screen between 2 Geiger counters (preceding abstract) gives a method for detn. of the absorption curve and range of the electrons. Even with 1 cm. Pb in between, coincidences were still observed in the records of the instruments. The electrons causing this effect are attributed to cosmic radiation.

B. J. C. VAN DER HOEVEN

The γ -ray spectrum of radiothorium in emission. L. MEITNER. *Z. Physik* 52, 645-9(1928).—Thibaud (*C. A.* 20, 1943-4) has found two γ -rays for Rd-Th at 145 and 168 X. U. The second line could not be observed indirectly by studying the β -ray spectrum of Rd-Th. A repetition of the measurement on Rd-Th with and without the decompn. products shows that the line at 168 X. U. is really double and belongs to Th B.

GEORGE GLOCKLER

γ -Radiation and evolution of heat of radium and mesothorium. D. K. YOVANOVITCH. *J. phys. radium* [6], 9, 297-306(1928).—A calorimetric method for the evaluation of the amount of Ms-Th contained in Ra salts is offered. The method is based on measuring the heat given off in the formation of Rd-Th. A microcalorimeter is used.

L. D. ROBERTS

Theory of scattering of electrons and impact probability. J. HOLTSMARK. *Z. Physik* 52, 485-95(1928); cf. *C. A.* 22, 2710.—Mathematical. GEORGE GLOCKLER

The reason why an elementary quantum of electricity cannot break up into smaller charges. WILHELM ANDERSON. *Ann. Physik* 87, 536-42(1928).—If an electron or proton exploded into infinitesimal particles the resultant gas must be fully degenerate, and according to the Fermi statistics must have infinite energy, which is impossible. If the elementary charges are supposed to be spheres of space-distributed charge, Fermi statistics show that there must be a min. charge that can explode. This min. depends on the spread of the charge, and is of the order of the charge of an electron or proton.

F. R. BICHOWSKY

Liberation of electrons from metal surfaces by slow positive ions. O. KLEMPERER. *Z. Physik* 52, 650-3(1928).—The probability of liberation of an electron from a metal surface by means of a positive ion is calcd. in two different ways: (1) from measurements of current-potential relations by Townsend and (2) from the min. sparking and ionization potential for electrons in gases. The two methods of calcn. check.

GEORGE GLOCKLER

Oscillating discharges in hydrogen. Z. BAY AND W. STEINER. Univ. Berlin. *Z. Elektrochem.* 34, 657-62(1928); cf. *C. A.* 23, 1052.—The continuous H spectrum is always obtained by oscillating discharges through thoroughly dry gas in well-dried electrodeless quartz tubes. This spectrum is to be attributed to H, not to impurities. Several types of tubes have been constructed. They are specially suitable for high c. d., they give a very intense continuous H spectrum, and they are good sources of high absorption measurements between 3300 and 1900 Å. U. ALBERT L. HENNE

The electric charging effect of glass by cathode rays. Its practical application. P. SELENYI. Lab. "Tungsram," Budapest-Ujpest. *Z. tech. Physik* 9, 451-4(1928).—In an electron tube of high vacuum with perforated plate (acting as grid element) and circular Mg anode (10 to 12 kv.) on the side wall the cathode rays reaching the back wall leave traces which can be "developed" on the outside of the tube by dusting with S powder. The effects of magnet coils with alternating field can thus be made visible, a single exposure suffices, i. e., for 1 μ amp. intensity of the (focused) radiation the writing velocity is 3000 cm. per sec., corresponding to 1 e. s. u. per cm. The curves obtained shown from photographs are quite sharp. Under special conditions peculiar light and shadow effects appeared on the irradiated glass, depending on the cond. of the latter.

B. J. C. VAN DER HOEVEN

Abnormal "g" values in the spectrum of ionized argon (A II). C. J. BAKKER. Lab. "Physica," Univ. Amsterdam. *Verslag Akad. Wetenschappen Amsterdam* 37, 835-9(1928).—Calcn. on the basis of the coupling scheme of Russell and Saunders (*C. A.* 19, 1661) of g values for the A II spectrum. Four different classifications are developed and compared with observed values for terms between 4p and 5s; none of them is exactly correct.

B. J. C. VAN DER HOEVEN

The Zeeman effect in the spectrum of ionized neon (Ne II). C. J. BAKKER. Univ. Amsterdam. *Verslag Akad. Wetenschappen Amsterdam* 37, 890-7(1928).—The expl. app. was that of previous work on A (cf. preceding abstract); Ne pressure was 2 to 3 cm.; field 41,400 gauss max. The g values (Landé) of terms from the 3s and 3p electrons were specially detd.; the results are given in tables. For the 3s electrons all normal g values were found. For 3p two anomalous ones (3p²S, and 3p²P) occurred. The sum rule was confirmed.

B. J. C. VAN DER HOEVEN

Note on the communication: The Zeeman effect of the spectrum of ionized argon (A II). C. J. BAKKER, T. L. DE BRUIN AND P. ZEEMAN. Univ. Amsterdam. *Verslag Akad. Wetenschappen Amsterdam* 37, 840-1; *Proc. Acad. Sci. Amsterdam* 31, 780-99 (1928); cf. *C. A.* 22, 2326.—Owing to a slight error in the visual observation of the multiplets of the Zeeman effect several values are now given from improved photometric measurements. They agree better with the theory.

B. J. C. VAN DER HOEVEN

A predecessor of the quantum theory. M. FAERBER. *Naturwissenschaften* 16, 1045(1928).—A historical note on Fechner.

B. J. C. VAN DER HOEVEN

Structure of the spectrum of ionized Argon (A II). T. L. DE BRUIN. *Proc. Acad. Sci. Amsterdam* 31, 771-9(1928).—See *C. A.* 22, 4371.

E. H.

The spectra of ionized neon (Ne II) and ionized argon (Ar II). (Second communication.) T. L. DE BRUIN. *Proc. Acad. Sci. Amsterdam* 31, 593-602(1928).—See *C. A.* 22, 2326.

E. H.

Electrical polarization in insulators produced by acceleration. E. BRODY. *Z. Physik* 52, 884-9(1928).—The possibly induced elec. moment in crystals produced by a gravitational or rotational field is calcd. The magnitude of the effect depends on the relative masses of anion and cation.

GEORGE GLOCKLER

Diffraction of cathode rays by mica. III. SEISHI KIKUCHI. Inst. Phys. Chem. Research. *Proc. Imp. Acad. (Japan)* 4, 354-6(1928); cf. *C. A.* 22, 4052.—A further discussion and description of the black and white lines, previously mentioned, is given. IV. *Ibid* 471-4.—By using monochromatic rays, the previous view is confirmed that the net-like pattern may be due to the diffraction by a 2-dimensional lattice, of which scattering centers are arranged in an equilateral triangular net work. The origin of the sets of concentric rings and pairs of black and white lines is also confirmed.

C. J. WEST

The role of conductivity electrons in ferromagnetism. J. DORFMAN AND R. JAANUS. Phys. tech. Lab., Leningrad-Soosnovska. *Naturwissenschaften* 16, 1026(1928).—From

the magnetomechanic behavior of ferromagnetic substances it is probable that the "spin" moment, not the orbital moment of the electrons, causes ferromagnetism. The authors endeavor to decide whether it is due to the free cond. electrons or to the electrons bound in the pos. metal ion. At the Curie point the heat motion of the elementary magnets destroys the ferromagnetism; at the same point therefore the sp. heat of the elementary magnets will show a discontinuous change, which had already been demonstrated calorimetrically. Considering the metal as a mixt. of ions and electrons it remains uncertain, however, to which one this change is due. A decision is possible by means of W. Thomson's thermodynamic theory for the thermoelec. effect: $eT(d^2E/dT^2) = \sigma_A - \sigma_B$, in which σ is sp. heat of the cond. electron (per electron) in metal A and B . By using for A and B Ni and Cu or Pt, resp., a ferromagnetic and a nonferromagnetic metal, the value of $T(d^2E/dT^2)$ was measured between 220° and 460° (Curie point at 360°). Actually a jump in σ_A was observed identical in magnitude and direction with the calorimetrically detd. jump for Ni (per atom). It means that for Ni the free electrons, equal in no. to the atoms, cause ferromagnetism. Preliminary data show that for Fe and Co the same conclusion holds.

The magnetic moment of the lithium atom. J. B. TAYLOR. *Z. Physik* 52, 846-52 (1928).—If it is assumed that the magnetic moment of the Li nucleus can only assume a parallel or an antiparallel position in the field, then the expts. show that the magnetic moment of the Li nucleus is less than $1/3$ Bohr magneton. The method of Stern and Gerlach was used.

Zeeman effect and term order in single ionized chromium. E. KRÖMER. *Z. Physik* 52, 531-48 (1928).—The Zeeman effect of 50 Cr^+ lines is studied and the magnetic fine structure factors are detd. The term system so found agrees with theory. The electron configuration for each term-multiplet is detd.

The influence of hydrogen on the photoelectric emission of potassium. R. SUHRMANN AND HANS THEISSING. Univ. Breslau. *Z. Physik* 52, 453-63 (1928).—Purified, dried mol. H_2 has no influence upon the photoelec. emission of a solid K surface. However, a monomol. layer of K on a spongy Pt surface has its emission considerably reduced when satd. with mol. H_2 . An elec. discharge has an enormous influence upon the photoemission of K.

The properties of Fournier photoelectric cells. R. DUBOIS. *J. phys. radium* [6] 9, 310-36 (1928).—These cells consist of a very thin deposit of metallic sulfides whose resistance varies with illumination. Their properties differ from Se cells, with sensibility extending into the visible and infra-red, $\lambda = 0.5\mu$ to $\lambda = 1.3\mu$. Their properties are very complex.

Recommended equipment of a modern x-ray laboratory for the study of structures of materials. GEORGE I. CLARK. Univ. of Illinois. *Ind. Eng. Chem.* 20, 1386-90 (1928).—A detailed description is given of the various types of complete x-ray app. such as may be employed advantageously in the study of fine structures of materials by the diffraction method. The equipment is essentially that installed in the new x-ray lab. at the Univ. of Illinois. The more important improvements are special cassettes for the pinhole and oscillation methods to be used with the multiple-diffraction app.; the design and set-up of gas-type, copper-target tubes with the power plant to operate these; a fine leak to regulate air pressure in these tubes; details of manipulation based upon experience; the applicability of various methods to certain types of problems; reproductions of typical diffraction patterns obtained in the study of industrial materials and processes; enumeration of useful auxiliary equipment for a laboratory of this type. In general, an effort is made to give an est. of the present status of the problem of the most dependable and economical installation of x-ray app.

The determination of chemical composition by means of x-rays. P. GÜNTHER. Berlin. *Z. Metallkunde* 20, 394-9 (1928).—The explanation of the origin of the different lines in the x-ray emission and absorption spectra is presented at some length in terms of the Rutherford-Bohr atom. The identification of an element can be made by means of x-ray spectra with relative simplicity because of the relatively few lines compared with optical spectra and because of the simple relationship connecting the wave lengths with at. no. For the quant. detn. of constituents a method depending on adsorption is preferable. This does not require that the material investigated be placed inside the x-ray tube. The absorption edges are characteristic of the elements with only very little change as the result of chemical combination. In favorable cases the process based on measurement of the absorption edges has been developed to a precision and sensitivity comparable to that of chem. analysis. So many factors influence the intensity of the different lines of the emission spectra that quantitatively it is not usable

except in very special cases where calibrations can be made; but recently published work by Glocker (cf. *C. A.* 22, 2880) has demonstrated the possibility of a quant. method making use of secondary radiation. This has the manipulative advantage again that the material does not have to be on the inside of the x-ray tube.

A. W. KENNEY

Applying of Röntgen rays to the investigation of materials. B. LÁNYI. *Technika* (Budapest) 9, 247-51(1928).—A short description of the new Röntgen app. of the Electrochem. Inst. of the Univ. for Technical Sciences at Budapest, Hungary. The investigations of materials which can be made with the app. are briefly summarized.

Š. S. DE FINÁLY

Total reflection of x-rays. V. E. LASHKAREV AND S. D. HERTZRÜCKEN. *Kiew. Z. Physik* 52, 739-42(1928).—A simple total reflectometer for x-rays is described.

GEORGE GLOCKLER

K radiation of the light elements (beryllium to aluminum). M. SODERMAN. *Z. Physik* 52, 795-808(1928).—The wave lengths of the K series of the elements from Be to Al were measured by means of an optical grating of 220 lines per mm.

GEORGE GLOCKLER

X-rays produced by α -rays. W. BOTHE AND H. FRÄNZ. *Z. Physik* 52, 466-84(1928); cf. *C. A.* 22, 1902.—The K, L and M lines of the x-ray spectrum of various elements were excited by means of α -rays from Po. The general radiation is very small in intensity. An attempt is made to det. the ionization function. G. G.

Relation of multiple terms and series limits. F. HUND. *Z. Physik* 52, 601-9(1928).—Theoretical discussion of assignment and designation of terms in band spectra.

GEORGE GLOCKLER

Spectrographic investigation of spark discharge. UKITIRŌ NAKAYA AND YOSHIO FUJIOKA. Inst. Phys. Chem. Research, Tokyo. *Proc. Imp. Acad. (Japan)* 4, 464-6(1928). Photographs are given of the spectrum of a "three-part" spark and of a flame like violet spark. In the former there are 3 distinct zones, corresponding to the positive, middle and negative parts of the spark. The "short" spark with "splitted" structure resembles the middle part of the 3-part spark. The broken-line spark, obtained by attaching a needle to the negative electrode has a stronger elec. field in the positive than in the negative part. The flame-like spark spectrum consists of well-developed positive band systems of N. C. J. WEST

Time lag in the emission of spectral lines excited in vacuum. HANTARO NAGAOKA AND TETSUGORO FUTAGAMI. Inst. Phys. Chem. Research, Tokyo. *Proc. Imp. Acad. (Japan)* 4, 361-3(1928).—Photograms taken in vacuum by applying a strong magnetic field revealed an easy means of distinguishing arc and spark lines. The discharge took place when the vacuum reached a state of producing green fluorescence. During the initial phase of the discharge, the gases remaining in the cylinder give rise to emission of arc lines. Many spark lines are emitted but the arc lines do not appear at the initial moment. It takes a half oscillation (about 10^{-8} sec.) or more before the lines appear; they go on increasing in intensity, reach a max. and gradually fade away. An explanation is offered. C. J. WEST

The polarization of light from hydrogen canal rays. ANTON WEIGL. Univ. Prag. *Naturwissenschaften* 16, 1042(1928).—The polarization of H canal-ray light in an elec. field with lines of force perpendicular to the canal ray is such that the degree of polarization decreases with increasing field down to zero; further increase of the field gives a linear polarization in the field direction which approaches a satn. value. For a 45° angle between field and canal ray the linear polarization becomes elliptical, for a 600 v. per 3 cm. field, almost circular. The observations were visual by interference polariscope; pressure 0.1 mm. Hg. The results are in agreement with Hanle's theory (*C. A.* 20, 2117). B. J. C. VAN DER HOEVEN

Polarization of radiation in helium and neon. K. STEINER. *Z. Physik* 52, 516-30(1928). The degree of polarization of radiation produced by a 50-v. electron beam from a hot cathode is studied. GEORGE GLOCKLER

Depolarization of secondary radiations in the complex light resulting from the molecular diffusion of a monochromatic radiation. JEAN CABANNES. *Compt. rend.* 187, 651-6(1928).—Depolarization measurements on the mol. diffusion of C_6H_6 and Et_2O lead to the conclusion that: If a liquid is radiated with different radiations N, N', \dots , all the secondary rays $N - n_1, N' - n_1, \dots$, relative to the same diminution of frequency, have the same depolarization, which varies widely according to the diminution of frequency considered and may be less (or more) than the depolarization of radiations diffused without change in wave length. The results are discussed and explained in terms of Raman's (*C. A.* 22, 1079; 23, 37) recent discoveries. A. T. F.

Intercombination and new terms in the spark spectrum of sulfur (S II). LÉON AND EUGÈNE BLOCH. *Compt. rend.* 188, 160-2(1929).—Intersystem combinations in the spectrum of S II are given which link together the systems of doublet and quartet terms already established. Combinations between the new terms and those already known are also given. C. C. KIESS

The absorption spectra of oxygen and ozone in the ultra-violet. J. DUFAY. *Compt. rend.* 188, 162-4(1929).—A table is presented in which the wave lengths of the ultra-violet absorption bands of liquid O and gaseous O under high pressure are compared with those ascribed to ozone. The agreement between the 2 appears to be more than accidental. This is supported by the fact that in the ultra-violet beyond 2400 Å. U. the absorption of "ozone" becomes continuous as does that of compressed O. C. C. KIESS

The progression of values of the K absorption edges of simple substances. V. DOLEJŠEK AND K. PESTRECOV. *Compt. rend.* 188, 164-6(1929).—New measurements of the K absorption limits of Fe, Co, Ni, Cu and Zn are given, which together with those detd. by others for elements of at. nos. 15 to 25, give values for ν/R which are well represented by the formula $\nu/R = a' + b'N + c'N^2 + d'N^3 + e'N^4$. The differences between the observed and computed values for the elements Na to Zn vary periodically, being greatest but of opposite sign near $N = 21$ (Sc) and $N = 29$ (Cu). C. C. KIESS

The ultra-violet spectra emitted by a mixture of hydrogen and mercury vapor. HENRYK JEZEWSKI. University of Warsaw, Poland. *J. phys. radium* [6] 9, 278-96(1928); cf. C. A. 22, 4370. C. C. KIESS

Structure of the third-order spectrum of sulfur (S III). J. GILLES. *Compt. rend.* 188, 63-4(1929).—Forty lines of S III, between 4528 and 3323 Å. U. have been classified as resulting from combinations of S, P and D terms of the triplet system. C. C. KIESS

Intensity relations in the spectra of titanium. I. Line intensities in the stronger multiplets of Ti I and Ti II. GEORGE R. HARRISON. Stanford Univ. *J. Optical Soc. Am.* 17, 389-416(1928).—A method of photographic photometry is described which was applied to det. the intensities of lines in the arc and spark spectra of Ti. Detailed results are tabulated for 26 multiplets of Ti I and 8 of Ti II. The measured relative intensities were in agreement with the theoretical intensities in more than half the multiplets examd. in each spectrum. And in the abnormal multiplets the majority of the lines had intensities agreeing with theory. Of all the lines measured 86% had intensities agreeing with theory. No definite correlation was found between intensity abnormalities and departures from Landé's interval rule, although in 17 multiplets having abnormal intervals 10 had abnormal intensities. C. C. KIESS

The continuous spectrum of mercury. JOHN K. ROBERTSON, K. A. MACKINNON AND W. H. ZINN. Queen's University, Kingston, Canada. *J. Optical Soc. Am.* 17, 417-27(1928).—The continuous bands of Hg with intensity max. at 4600, 3300, and 2536 Å. U. were obtained either by rolling a drop of Hg horizontally in an evacuated and heated quartz tube or by exciting the same tube, when heated, with a high-frequency electrodeless discharge. When the latter method of excitation was employed a fourth band with max. intensity at 2650 Å. U. was also obtained. The spectrum thus obtained appears to be identical with that observed in fluorescent vapor, and in vapor subjected to electronic bombardment. Conclusion: The radiation emanates from excited mols., and is not due to a recombination of an electron with an ionized atom to change it from the $(p+1)$ th to the p th state, as suggested by Balasse (C. A. 22, 1277). C. C. KIESS

Transmission of ultra-violet radiations by quartz prism monochromators. WM T. ANDERSON, JR., HUGH D. FRASER AND LESTER BIRD. Hanovia Research Lab. *J. Optical Soc. Am.* 17, 454-62(1928).—A new design of ultra-violet monochromator is described which favors the transmission of the shorter wave lengths. The instrument transmits about 11% of the incident ultra-violet radiations. C. C. KIESS

Transfer of excited mercury atoms to the metastable state. H. KLUMB AND P. PRINGSHEIM. *Z. Physik* 52, 610-26(1928).—The absorption of λ 4047 in Hg vapor with addn. of other gases (He-Nc, A, N₂, CO, CO₂, H₂O) was studied. The line was produced in a water-cooled arc and the absorbing Hg vapor was illuminated at right angles so as to produce a few Hg atoms in the 2^3P_1 state. The absorption was studied as a function of the pressure of the added gas, the pressure of impurities and the intensity of the light coming into the absorption vessel at right angles. The results are compared with certain theoretical deductions. The extreme effect in N₂ is thought to be due to a resonance phenomenon (2^3P_1 — 2^3P_0 0.21 v. and the vibration quantum in N₂ is 0.28 v.). GEORGE GLOCKLER

Intensity ratio at the edges of strongly reversed multiplets. W. BLEEKER. *Z. Physik* 52, 808-14(1928).—With the Na doublet $1s \rightarrow 2p$ it is shown that the intensity ratio near the edges of the lines approaches the theoretical value of 2:1. The same is true with the K and Zn doublets. In the Cs doublet the above ratio is 5.5:1 (cf. *C. A.* 22, 3582).

GEORGE GLOCKLER

Secondary radiation observed in the molecular diffusion of light by fluids (Raman effect). P. DAURE. *Compt. rend.* 186, 1833-5(1928).—The frequencies of the secondary radiations are given by the formula $N - n_p$, where N is the frequency of the exciting radiation and n_p represents the characteristic const. of the fluid and is probably related to its infra-red absorption spectrum. Values of the latter are given. It has been shown for Me_2O , EtOH , C_6H_6 , PhMe , and aq. solns. of salts that spectra of fluids having a common radical contain some rays in common, some different and some slightly displaced. Rays corresponding with the same molecular frequency have the same degree of polymerization, and the spectrum of a C_6H_6 - PhMe mixt. is superposition of the constituent spectra. The intensities probably depend on that of the exciting ray and of the molecular density.

ALBERT L. HENNE

The band spectrum of lithium. K. WURM. Einstein Inst., Astrophys. Observat., Potsdam. *Naturwissenschaften* 16, 1028(1928).—Of the two visible Li absorption band systems (blue-green and red) the first one has been classified by a nucleus vibration scheme. The fluorescence spectrum of Li at 600° to 700° in sunlight is identical with it. A table of its frequency values is given. Dispersion is 14 Å. U. per mm. and 138 Å. U. per mm. for some. The edge formula obtained is $\nu = 20398.4 + (267.5n' - 3.2n'^2) - (347.5n'' - 2.2n''^2)$, from which a dissociation energy of 1.69 v. for the unexcited molecule follows.

B. J. C. VAN DER HOEVEN

Helium bands. Y. FUJIOKA. *Z. Physik* 52, 657-67(1928).—The difference in relative intensity of He bands when excited with d. c. and condensed discharge is studied. Two bands, which appear more strongly in d. c. excitation, are analyzed in detail.

GEORGE GLOCKLER

Band spectra of carbon monoxide. GERHARD HERZBERG. *Z. Physik* 52, 815-45 (1928).—In an electrodeless ring discharge a new band system of CO is found, with the same final state as the Ångström bands. The initial state is a 1D -state. A series of observations on the intensity distribution on these bands shows an analogy to certain N_2 bands. An energy diagram is given and the dissociation of CO and CN are discussed. The behavior of the Swan and CN bands in electrodeless discharge is described.

GEORGE GLOCKLER

A new band spectrum of carbon monoxide. GERHARD HERZBERG. *Tech. Hochschule, Darmstadt. Naturwissenschaften* 16, 1027-8(1928).—Continuing the work on electrodeless ring discharge in N_2 (*C. A.* 22, 3354, 3582) H. examd. CO in a similar way. Weak excitation and 1 mm. pressure gave the well-known Ångström bands. Group "a" was very intense, group "b" failed to appear. In the neighborhood of "b" a group was found like the others in fine structure (30 to 10 Å. U. per mm. dispersion needed), and in dependence on discharge conditions and intensity distribution. In Birge's (*C. A.* 21, 1062) edge scheme the new bands could not be classified however, the value of n being 2.5 from the const. frequency difference between the new group and group "a" (5004 per cm.). It is concluded that the initial term of this group is one different in electron arrangement from that of either of the Ångström bands. It is called the "C" condition; it lies at 91898 per cm. (the Ångström "c" is at 92086). Wave lengths and frequencies of the new bands are given in a table and compared with the "a" bands.

B. J. C. VAN DER HOEVEN

New absorption vessel of variable length. C. LEISS. *Z. Physik* 52, 748-9(1928).—A container for liquids whose absorption of light is to be measured is so designed that the liquid can come into contact with glass only.

GEORGE GLOCKLER

Measurement of light absorption. H. VON HALBAN AND J. EISENBRAND. *Z. phys. Phot.* 25, 138-52(1928); cf. *C. A.* 21, 3831.—The different photoelec. cells show unexpectedly large variations, which need explanation, in the dependence of sensitivity on wave length. Exact knowledge of the properties of the cells employed is especially of importance when measurements have to be carried out with not quite monochromatic light.

E. R. BULLOCK

The action of light rays upon potassium chloride. JACQUES RISLER AND ROYAU DE COUMELLERS. *Compt. rend.* 187, 944-5(1928).—KCl exposed to sunlight and subsequently placed on photographic plates in a dark room registered a photographic impression. On testing different sources of light and different filters it was shown that unfiltered ultra-violet rays produced this effect most rapidly. The authors attach

some significance to these results in view of Zwardemaker's observation of the effect of season in the role of the cardiac action of KCl. The increase in microradioactivity of KCl under the action of luminous rays explains the particularly energetic function of the element in the growth of plants under the action of sunlight. L. T. F.

Fluorescence of fluorspars excited by light of different wave lengths. HISAMITU NISI AND KYŪTIRO MIYAMOTO. *Kyushu Imp. Univ. Proc. Imp. Acad. (Japan)* 4, 357-60(1928).—Fluorspars are classified into 3 groups—those which show blue and red fluorescence, those which show blue only and the 3rd, which have no appreciable fluorescence. The 1st group is here studied. Results are tabulated for the Cd, Fe, Mg and Ni spark and the Fe, Hg and Ni arc. The wave lengths of definite fluorescent lines are const. within the exptl. error, whatever the exciting source may be and nearly const. for different specimens. The blue fluorescence practically disappears when Wratten esculin filter or Wood's glass of about 2 cm. is inserted between the specimen and the exciting source, but a thin Wood's glass has no appreciable effect upon it. Thus, the principal wave lengths able to excite the blue fluorescence is less than 3850 and greater than 3000 Å. U. The red fluorescence is excited by wave lengths from Fe, Ni and Mg sparks of about 2300, 2500 and 2800 Å. U. C. J. WEST

Influence of magnesium metal on the formation of formaldehyde and sugars by the action of ultra-violet rays on calcium bicarbonate solutions. G. MEZZADROLI AND E. VARETON. *Atti accad. Lincei* 8, 511-5; *Zymol. chim. col. e zucch.* 3, 165-71(1928). When a soln. of $\text{Ca}(\text{HCO}_3)_2$ (of about $p_H = 7.5$) is exposed to ultra-violet rays small amts. of CH_2O and sugars are formed. If Mg metal is added, in an open vessel, somewhat more of the reducing substances are formed, while if the reaction is allowed to take place in a closed quartz vessel considerably larger amts. of sugars are formed; represented as cc. 0.1 N I_2 , the max. reduced is 1.2 cc. in 1st instance, 1.5 cc. in 2nd, while in quartz = 2.9 cc. I_2 are used up, although a longer time is required to attain this figure. Mg may act to remove O_2 formed which would, otherwise, destroy the products by oxidation as fast as formed. A. W. CONTIERI

Preliminary studies of action of light on silver nuclear hydrosols and their derivatives. A. GALECKI AND R. SPYCHALSKI. *Roczniki Chem.* 8, 394-404 (404 German) (1928).—The silver nuclear hydrosols and their derivs. were prepd. according to Galecki and Kempf (*C. A.* 22, 4027) and electrometric, viscosity, and cond. measurements of illuminated hydrosols performed. Hydrosols subjected to ultra-violet illumination were decolorized the more readily, the smaller were the colloidal particles of sols. The increased cond. and decreased viscosity point to the partial conversion of Ag into ions. On further illumination with ultra-violet light the process is reversed, whereby the Ag ions, just formed, are reduced out as colloids. All the consecutive changes in various portions of the same sols, prepd. separately, differ considerably. Also in *Z. anorg. allgem. Chem.* 177, 337-44(1928). JAROSLAV KUČERA

The action of x-rays on chloroform and similar compounds. PAUL GÜNTHER, H. D. VON DER HORST AND GEORG CRONHEIM. *Phys.-chem. Institut, Berlin Z. Elektrochem.* 34, 616-25(1928); cf. *C. A.* 15, 2241; 22, 3841. The source of x-rays in this work was a Coolidge tube with an Fe target and a Lindemann window. The tube was operated at 50-75 kv. with 1-3 milliamp. The material radiated was about 10 cm. from the focal point and was contained in a vessel about 10 mm. wide inside of thin Jena glass. When HCCl_3 is radiated with x-rays, HCl is formed in amts. proportional to the energy input, provided that the character of the radiation is const. The HCl was detd. by extn. with H_2O and subsequent titration. By changing the distance between the sample and the x-ray tube it was shown that the yield was inversely proportional to the square of the distance. HCCl_3 in different degrees of purity gave fairly reproducible results. Hexachloroethane is one of the products of the decomposition. Although other org. products could not be identified, presumably other compds. of C, Cl, and H are formed. The yield of acid depends to a large degree on the amt. of H_2O present in the HCCl_3 . In a sp. instance about four times as much acid formed in HCCl_3 satd. with H_2O as in HCCl_3 dried with Na. The effect of the hardness of the x-rays on the yield was observed by using filtered radiation; the harder x-rays are more effective. If CCl_4 is radiated with x-rays Cl_2 is formed, but in extremely small amts. In the presence of other solvents such as ligroin or cyclohexane much larger, though still small, quantities of HCl are formed, suggesting a reaction between CCl_4 and ligroin. It is to be noted that photochem. reactions may be induced by x-rays which are not at all affected by visible light, but there is evidence in the optical region to indicate that the splitting off of HCl and its oxidation in the presence of H_2O and O_2 can take place. HCl_2 was studied in a manner similar to HCCl_3 . I_2 was liberated, presumably the result of a primary splitting off of HI and subsequent

oxidation by O_2 of the air. Mixts. with ligroin and cyclohexane were studied, but the greatest effect was produced in mixts. of HCl_3 and $HCCL_3$. The fact that I_2 is set free when HCl_3 is added to $HCCL_3$ which has been radiated with x-rays has been ascribed to the formation of $HOCl$ from the $HCCL_3$. Quantitatively this explanation is not sufficient and it is suggested that some other compd. than HI forms and can be oxidized by the air. This, in analogy to CCl_4 above, may be a compd. between $HCCL_3$ and ligroin. When the concns. are varied it is found that beyond a certain point the addn. of more ligroin does not have any effect; and from this concn. calcns. indicate the possibility of a combination between 117 mols. octane and one HCl_3 . In the absence of atm. O_2 and in pure $HCCL_3$ the yield of I_2 is proportional to the HCl_3 concn. The photochem. effect of radiation from Ra is presumably similar to that of x-rays.

A. W. KENNEY

Oxidations promoted by ultrasonic radiation. F. O. SCHMITT, C. H. JOHNSON AND A. R. OLSON. Univ. of Calif. *J. Am. Chem. Soc.* **51**, 370-5(1928).—Ultrasonic radiation was found to cause an oxidation of iodide ion, and so to affect bromide and chloride solns. that they would immediately liberate I_2 from KI . The formation of H_2O_2 in the solns. is suspected on the basis of positive evidence with the titanium sulfate reagent; O_3 may be formed but was not indicated by the tests. H_2S solns. give colloidal S when radiated. Aqueous CCl_4 solns. contg. starch and KI become intensely colored; CCl_4 and aq. KBr (two-phase system) impart a yellow coloration of Br_2 to the water when treated. Ferric ion solns. with H_2 are not affected. Bromothymol blue is altered, the blue-green cast giving way to yellow upon radiation (the H -ion concn. increases). This work may tend to vitiate the studies of Richards and Loomis (*C. A.* **22**, 721). The pressures of O_2 above KI and H_2S solns. were varied and there was found a crit. pressure above which a diminution in reaction rate occurred; pressure apparently influences the formation of H_2O_2 .

WILLIAM E. VAUGHAN

Theory of the valence octet in the torulus atom. I. General theory. DAN RADULESCU. *Bul. soc. stiinte Cluj* **4**, 263-79(1928).—The fundamental hypotheses of the torulus atom (cf. *C. A.* **18**, 2640) lead to the octet theory. They make it possible to predict, without accessory assumptions, the stability of chem. substances, the polarity of the various components of the mol., the structure of coordination compds., and their general properties. **II. The valence octet theory in organic chemistry.** *Ibid* 280-91.—Present symbols are grossly insufficient. The use of symbols based on the electronic valence octet affords a decided improvement. Physical and chem. properties of conjugated double bonds can be predicted. Formulas are proposed for benzene, naphthalene and anthracene. These formulas explain the role of the substituting group polarity. **III. General relations between the absorption spectrum and the chemical properties of organic substances. General resonance theory.** *Ibid* 292-305.—A new absorption theory is proposed; general resonance is defined. The so-called "slackening" of the valence electrons is discussed. The Staudinger law is erroneous. A general theory of selective absorption is outlined. **IV. New examples of relations between the absorption spectrum and the chemical properties.** *Ibid* 306-11.—Relations have been found between the red front of the absorption bands and the chemical properties of the chromogens: these relations are exactly the contrary of what was expected from the Staudinger law. The results are easily explained by the general resonance theory. **V. New general theory of halochromy.** *Ibid* 213-22.—Examples are given, explaining the constitution of the metallic derivatives of Schlenk and Bergmann (*C. A.* **22**, 4493) of triarylmethyls and the so-called "carbonium" salts. A general theory of the "true halochromy" and of the coordination halochromy is discussed. The structure and constitution of the resonators are developed in every case. **VI. Relations between photochemical properties and polarity of the substituting groups in the octet theory.** *Ibid* 323-5.—Photochemically active nitro derivatives have a mobile H; polarity of the substituting groups is of great importance. This is easily explained by the torulus electronic octet theory. **VII. New general theory of fluorescence and phosphorescence.** *Ibid* 326-32.—A new theory is proposed, based on the general resonance theory. Fluorescence is due to harmonic oscillation of the resonators, without infra-red harmonics, i. e., without at. vibration. From this a very simple theory of fluorescence and phosphorescence is derived, which is in perfect agreement with exptl. data. A. L. H.

Arsenides of Mg and Zn (NATTA, PASSERINI) 6. Some physical constants of Re (NODDACK) 2. Ionization potentials and grating energies of atoms in the solid state (BISWAS) 2. A fluorescent salt for x-ray screens, calcium tungstate. M. G. BOGOSLOVSKII, A. A. MAMUROVSKII and P. V. SAVITZKAYA. Russ. 5013, Mar. 31, 1928. CaWO_4 is prepd. by fusing wolframite with soda, dissolving the melt in water, pptg. CaWO_4 by means of CaCl_2 , heating in a muffle furnace, and then adding 0.01 to 0.5% of tin oxide.

Fluorescent salts for x-ray screens. M. G. BOGOSLOVSKII, A. A. MAMUROVSKII and P. V. SAVITZKAYA. Russ. 5012, Mar. 31, 1928. Compounds which are used in fluorescent screens for x-ray apparatus are prepared from ZnSO_4 and MgSO_4 pptd. from soln. by means of water glass and soda. One part by wt. of this ppt. is dried at 150–200° and mixed with 0.2 to 1 part of dry NaCl, heated to 1200–1300° and the NaCl is finally washed off with water.

4—ELECTROCHEMISTRY

COLIN G. FINK

A simple high-frequency vacuum furnace for laboratory use. F. W. FELL. Tech. Hochschule Aachen. *Arch. Eisenhüttenwesen* 1, 659–61(1928); cf. C. A. 22, 2718 — An induction furnace for melting 1–1.5 kg. of metal, operating at 8000 cycles and giving a vacuum of 0.5–3 mm., $\frac{1}{2}$ hr. after starting the pump, is described. Essentially, it consists of a bell-jar (300 mm. diam. and 440 mm. high) which sets on a glass plate with an air-tight joint. Inside the jar is placed a crucible thermally insulated from the rest of the app. with Al_2O_3 and H_2O jackets, and surrounded by an induction coil (Cu tubing 160 mm. high, exterior diam. 160 mm. and interior diam. 110 mm.). Means of obtaining the vacuum, of seeing into the furnace, and of making alloys are indicated.

J. BALOZIAN

Electric furnace for the firing of ceramic ware. MAURIZIO KORACH. Laboratorio Sperimentale Ceramico, Faenza. *Corriere ceram.* 9, 495–7, 499, 501, 503(1928). — K. emphasizes the value of elec. furnaces in the ceramic industry. He gives a detailed description of an elec. furnace built by the firm Scei (Novara).

G. SCHWOCH

Brown-Boveri electric furnaces with electro-hydraulic regulation of the electrodes. E. DE MULINEN. *Génie civil* 93, 143–5(1928); *J. four élec.* 38, 9–11(1929). — A large-capacity Heroult furnace (20 tons) installed in Italy is described. It consists of 3 essential parts: (1) furnace bed with crucible, 3 electrodes and auxiliary motor for moving electrodes, (2) electro-hydraulic automatic control arrangement for electrodes, (3) transformer and distribution app. The regulator operates with optimum pressure between 5 and 10 atm.; a small current excess causes a slow elevation of the electrodes while a short circuit causes elevation of electrodes at max. speed. The hydraulic motors are in the form of cylinders with a piston whose rod acts directly on the carrier of each electrode.

M. McMAHON

Electrothermic manufacture of yellow phosphorus. I. E. SHIKHUTZKII. State Inst. Appl. Chem. *J. Chem. Ind. (Moscow)* 5, 979–82(1928). — Preliminary to the installation of a factory for the manuf. of P by distn. of phosphorites and apatites with sand and coal, expts. were instituted to find the best operating conditions. It was found that if the mass is introduced into the elec. furnace in finely divided form it melts faster and the operation runs more smoothly than when using large pieces; in the latter case a greater expense of energy and a stronger current would be required, and this would lead to greater damage to electrodes and to apparatus. Continuous operation was found to be best, as it avoids the waste of heat required to warm up the furnace; considering that the mass, when it melts, occupies approximately half of its former volume, a new batch may be introduced without unloading the residue of the first. The sudden drop of temp. occasioned by the introduction of a new batch on the top of the old one can be avoided by adding the second batch in small portions which may preliminarily be heated to 200–300° by the use of the flues. Instead of using for the mixt. cryst. silica sand, it is advisable to use amorphous SiO_2 obtained by heating

kaolin up to 550°; with this grade of silica the operation takes place with a 21% decrease in expenditure of energy and a corresponding economy of time. B. N.

Industrial electric heating. The (electric) resistor furnace. N. R. STANSEL AND C. DANTSZEN. *Gen. Elec. Rev.* 32, 162(1929); cf. *C. A.* 23, 341.—A review.

J. H. MOORE

The progress of electrodeposition during 1928. SAMUEL FIELD. *Metal Ind.* (London) 34, 48(1929). F. C. M.

Wood's metal as cathode in electrolysis. H. A. J. PIETERS. *Chem. Weekblad* 25, 706-7(1928).—Wood's metal recommended by Paweck and Weiner (*C. A.* 22, 554) was found well suited for cathode material after purification with HCl. It was successfully used for electrolytic analysis of Cu, Cd, Zn, Hg, Ni and Co; it is not recommended for chlorides and nitrates. The results with Pb, Ag and Fe were unsatisfactory. A Pt spiral was used as anode. B. J. C. VAN DER HOEVEN

Electrochemical preparation of anthranilic acid. L. B. ALVAREZ. *Mon. farm. therap.* 34, 121-2(1928).—Sixty g. of *o*-nitrobenzoic acid was dissolved in a mixt. of 20 cc. of alc. and 100 cc. of H₂SO₄ and used as cathode liquid; 100 cc. of H₂SO₄ served as anode liquid. Lead and PbO₂ electrodes and a c. d. of 1 amp. were required. J. L. POWERS

Electrochemical synthesis of anesthesine. L. B. ALVAREZ. *Mon. farm. therap.* 34, 281 2(1928). The ethyl ester of *p*-nitrobenzoic acid was prepd. electrochemically, platinum electrodes being used. For anode liquid there was used a satd. aq. soln. of K *p*-nitrobenzoate and an equiv. amt. of K propionate, and for the cathode liquid a 10% aq. soln. of potassium propionate. Conversion of the nitro into the amino ester was effected by the addition of HCl to the reaction mixture which served as the cathode liquid. 10% H₂SO₄ was used around the anode. Lead and nickel electrodes were employed. J. L. POWERS

The question of the activation of hydrogen in the silent electrical discharge. GEORG-MARIA SCHWAB AND FRANZ SEUFERLING. *Z. Elektrochem.* 34, 654-7(1927).—Electrolytic H passed through an ozonizer at 50 mm. and then through S gives a test for HS about 10 times the blank (due to S in the glass of the ozonizer). Active H reacts with As, but its form is not identified. It may be atomic H. F. R. BICHOWSKY

Tube light as source of artificial daylight (Moore light). M. PÜCHLER. *A. E. G. Mitteilungen* 1929, 42 3.—Illustrated description of app. consisting of 5-m. long Moore-light tubes (CO₂ filled), movable window, transformer and switch, which operates on a c. with special current regulator with current consumption of 1 kw. The blue-white light obtained from tubes is particularly advantageous for spinning, weaving, color and paper industries. M. McMAHON

Life of glass in rectifiers on trains. H. SCHLEUSNER. *A. E. G. Mitteilungen* 1929, 2 1.—Glass rectifiers can be satisfactorily used on trains in place of iron rectifiers. On the basis of statistics a life of over 10,000 hrs. was obtained with glass rectifiers. M. McMAHON

Tests of bakelized paper. I. KUMLIK. *Elektrizitätswirtschaft* 27, 423 31(1928).—Paper prepd. from a series of (wood-free, thin glaze) paper layers either pressed in plate form or wound in the form of a wood cylinder with binding agent either of bakelite or shellac was tested for elec. properties. Various causes of puncture were considered: (a) failure to reach a final favorable state of bakelite or shellac with the result that chem. changes occur after they are applied to paper; (b) air content; (c) bubble-like formation was observed on microscopic investigation as the starting point of the spark which creeps along in canals before puncturing. Values obtained for hardness, cleavage, ductility, elasticity, absorption of water and oil are tabulated. M. McMAHON

Preventing electrolytic corrosion in steam condensers or other apparatus. E. CUMBERLAND. Brit. 293,909, April 19, 1927. In a system for preventing corrosion, such as that described in Brit. 277,417 (*C. A.* 22, 2518), lamps or other suitable fault-indicating devices are included across the actual or suspected source of stray currents.

Electrolytic precipitation of metals. HJALMAR F. SUNDBERG. Fr. 644,548, Sept. 15, 1927. Metals or metallic compds. of the 4th to the 7th group, such as Cr, Ta and Mo, are pptd. electrolytically using solns. in water, glycerol or pyridine, of simple or complex compds. of the metal at higher or lower degrees of oxidation, e. g., compds. contg. O and H, B, C, Si, N, S, Se, Te or P, such as a fluoborate, fluosilicate or selenate of the metal.

Nickel. SOC. ANON. "LE NICKEL." Fr. 643,879, April 13, 1927. See Brit. 288,605 (*C. A.* 23, 568).

Electrolytic diaphragm cell suitable for producing oxygen and hydrogen. WILLIAM G. ALLAN (to Farley G. Clark). U. S. 1,702,924, Feb. 19. Structural features.

Cell for electrolytic manufacture of oxygen and hydrogen. DE NORDISKE FABRIKER DE-NO-FA A.-S. and CARL FREDERIK HOLMBOE. Ger. 467,399, Nov. 16, 1924. The cell contains a no. of electrodes, the cathodes being enclosed in diaphragm-bags having a small hole in the bottom. Fresh addns. of electrolyte are made as required to the bags enclosing the cathodes.

Electrolysis of alkali chlorides. FRANZ GERLACH. Fr. 33,372, April 16, 1927. See Brit. 269,513 (C. A. 22, 1285).

Electrodeposition of iron. I. G. FARBENIND. A.-G. Brit. 293,442, July 8, 1927. In deposition for subsequent removal, e. g., deposition on a rotating cylinder from which the iron is continuously removed as a band, a cathode of "V2 A" steel or similar acid-resisting alloy is used.

Alloys. LE MATÉRIEL TÉLÉPHONIQUE (Société anonyme). Fr. 644,301, Nov. 21, 1927. Alloys of metals are obtained by depositing the metals electrolytically simultaneously on a cathode, the electrolyte being chosen so that the potentials at the cathode remain practically equal for the series of current densities used. The method is particularly useful for the formation of thin sheets of an alloy of Fe and Ni.

Electroplating apparatus. RIEDEL & Co. Ger. 470,517, Mar. 29, 1927. Means are described for vertically raising and lowering the rotary frames which carry the goods under treatment.

Electroplating apparatus. RIEDEL & Co. Ger. 470,681, Jan. 8, 1927. Improvements are described in the construction and arrangement of the spring grips holding the goods and of the arms which support the grips.

Electrolytic furnace for producing light metals such as aluminum. P. L. HULIN (to Compagnie de produits chimiques et électrométallurgiques Alais, Froges et Camargue). Brit. 293,353, July 4, 1927. Various structural features are specified.

Electric furnace of the tunnel type traversed by trucks. BERNARD J. MOORE, ARTHUR J. CAMPBELL and GIBBONS BROTHERS, LTD. Fr. 644,392, Nov. 23, 1927. Method of supporting the heating resistances.

Electric furnace for the production of iron, steel or steel alloys. EMIL G. T. GUSTAFSSON. Fr. 644,553, Sept. 26, 1927.

Electrode holder for electric furnaces. EINAR MOLMARK. U. S. 1,702,359, Feb.

Protective device for electrical apparatus. M. BUCHHOLZ. Brit. 293,705, July 8, 1927. Evolution of gas by decompn. in elec. transformers or switches under abnormal conditions is utilized to operate an automatic cut-out.

Electric conductors (wire) insulated with rubber overlaid with pyroxylin. GEORGE T. JONES (to Davis-Jones Insulated Wire Co.). U. S. 1,702,652, Feb. 19.

Electric conductors. ANTOINE BORENSZTEDT. Fr. 644,430. Elec. conductors are made on a basis of cellulose nitrate or acetate by adding to the cellulosic soln. 5-10% AgNO₃ and 1-3% HNO₃, reducing with H₂S and treating it in an electrolytic bath.

Electrical treatment of hydrocarbons and fatty oils. SIEMENS & HALSKE A.-G. Ger. 466,413, Aug. 5, 1923. The viscosity of hydrocarbons and fatty oils is increased by treatment under reduced pressure with a silent elec. discharge developed by 2 stationary electrodes, e. g., 2 glass electrodes or 1 glass and 1 metal electrode, in contact with the liquid under treatment. Comparatively pure H which may be used, e. g., for hydrogenating fats is generated in the treatment and renders the known practice of introducing gas from the outside unnecessary. Suitable app. is described.

Material for rectifying alternating electric currents. ALLGEMEINE ELEKTRICITÄTS-GES. (to Patent-Treuhand-Ges. für Elektrische Glühlampen). Brit. 293,300, July 2, 1927. A rectifier may consist of a Cu plate forming one terminal element, a Cu₂I₂ layer in contact with or formed on the plate and an iodide coating on a Ag or Pb plate forming the other terminal element. Details of manuf. are given.

Ozone generator using high-frequency alternating current. WILHELM ESMARCH (to Siemens & Halske A.-G.). U. S. 1,702,254, Feb. 19.

Electric gas-purification plant. OSCAR MURY, MARC PELET and SOCIÉTÉ D'ENTREPRISE ET D'EXPLOITATION ATELIERS D'ARLOD. Fr. 33,312, April 6, 1927. Addn. to 617,411.

Removing dust from gases. SIEMENS-SCHUCKERTWERKE AKTIENGESELLSCHAFT. Fr. 643,860, Nov. 15, 1927. Explosions in elec. app. for removing dust from gases are prevented by placing in the purification chamber a fusible wire so arranged that it will melt on the production of a fire and release safety devices connected therewith.

Electrothermic reduction processes. SOC. ELECTRO-MÉTALLURGIQUE DE MONT-RICHER. Ger. 466,755, July 28, 1926. The furnace is charged for the most part with the usual homogeneous mixt. of reducing agent and material to be reduced, but in the vicinity of the electrode this charge is interspersed with layers of a non-conducting material. Better lateral distribution of the current is so obtained.

Electric incandescent lamps. PATENT-TREUHAND GES. FÜR ELEKTRISCHE GLÜH-LAMPEN (to General Electric Co., Ltd.). Brit. 293,675, April 17, 1928. Caps are coated with a heat-resisting material which forms a thin and glassy layer for preventing their oxidation, especially during the cement-baking operation, as described in Brit. 285,009 (*C. A.* 22, 4393), and which also acts as a flux for soldering the leading-in wires. "Boric acid water-glass" comprising one mol. Na_2O to 3 or 4 mols. of B_2O_3 , or similar phosphoric acid compds., may be used.

5—PHOTOGRAPHY

C. E. K. MEES

Processes of color photography. F. J. TRITTON. *Nature* 122, 687-8, 701(1928). The color processes applicable to prints on paper in use are covered briefly; some of the difficulties involved are mentioned. Methods evolved by the Colour Photographs, Ltd., from the Martinez patents, are discussed in detail; better register and greater ease of manipulation by the use of cellophane films are claimed. Tri-packs, having 3 selectively light sensitive films, are also described.

R. M. EVANS

New effect of chromic acid on photographic plates. E. P. WIGHTMAN AND S. E. SHEPPARD. *Phot. J.* 68, 201-5(1928).—Certain plates made with inert gelatin were treated with chromic acid soln. and it was observed that they apparently showed fog and sensitivity increase above the untreated plate. This phenomenon has been investigated further and it has been found that the increase in sensitivity passes through a max. with time of treatment and finally for treatments of 4 hrs. or longer there is a small desensitizing effect. The phenomenon disappears when the plates are washed thoroughly in rapidly running water prior to desensitizing. The effect may be caused (1) by the liberation of Br from sol. bromide in the plate by the chromic acid- H_2SO_4 . The Br when set free may act, according to a hypothesis proposed by Hickman (*C. A.* 21, 1066) and Wightman and Quirk (*C. A.* 21, 1066). The effect may be caused also (2) by a lessening of the no. of competing sensitivity specks by the chromic acid, the remaining specks thus becoming more effective; or, (3) by the specific action of chromic acid on something in the gelatin giving rise to a new sensitizer. Acid- KMnO_4 does not produce the effect. This effect will be studied over a wider range of conditions

E. P. WIGHTMAN

Effect of environment on photographic sensitivity. I. S. F. SHEPPARD and E. P. WIGHTMAN. *Phot. J.* 69, 22-35(1929).—The reversible p_H effect upon the speed of emulsions as observed by Rawling (*C. A.* 21, 863; cf. also Rawling and Glassett, *C. A.* 537) has been investigated. Aged plates, treated by bathing, give small and uncertain effects. Fresh emulsions appear to show the effect more definitely. Considerably more work is required before the nature of the effect can be definitely established. The possible causes appear to fall in four classes: (1) an action on AgBr ; (2) an action on Ag nuclei; (3) an exhalation of a Br acceptor function of the Ag_2S nuclei during exposure as suggested by Hickman (*C. A.* 21, 1066); and (4) a reversible effect on gelatin.

E. P. WIGHTMAN

Influence of the fixing agent on post-fixation development of reversed or solarized photographic plates. H. BELLIOU. *Compt. rend.* 188, 167-9(1929).—Several fixing agents were used in alkaline as well as acid soln. prior to physical development with either Hg or Ag developers. The results with alk. bath confirm those of Lumière and Seyewetz that post-fixation development is impossible following an alk. fixing bath unless the sensitive grain centers have been pre-treated with a suitable reducing agent. It is concluded that the nucleus of the image consists of three kinds of grains: (1) those directly reduced by the exposure; (2) those which have been rendered developable by the formation of a latent image; (3) and some of those grains, immediately adjacent, which are acted upon by the fixing bath as a reducing agent.

G. A. C.

Artificial silk, films, etc. (Brit. pat. 293,350) 23. Plasticizing cellulose esters and ethers (Brit. pat. 294,008) 23.

Color photography. S. A. SPLENDICOLOR. Ger. 470,411, Feb. 10, 1928. Simultaneous application of color layers to the gelatin layers on both sides of a film is effected by pressing on to the film strips of gelatinized paper which carry the color layers and are allowed to remain in contact with the film for a sufficient time.

Lighting system for color photography. H. BERTLING. Brit. 293,709, July 9, 1927. In supplying colored light of graduated intensity, the red and yellow rays may be produced separately by tubular lamps, having, resp., cathodes of K and Na, with or without fillings of inert gases such as Ne and He.

Films for color photography. SOC. CIVILE POUR L'ETUDE DE LA PHOTOGRAPHIE ET DE LA CINEMATOGRAPHIE EN COULEURS. Brit. 293,306, July 2, 1927. The uncoated surface carries minute refractive elements, and the emulsion layer contains a coloring agent or neutral salt for subduing the activity of rays reflected in the layer without impairing the actinic efficiency of the direct rays. Dyes such as indulines may be used in emulsions for making negatives and tartrazine in emulsions for making positive; salts such as Ag chromate also may be used and are added to the emulsion before coating. The dyes may be added either before or after coating.

Photographic sensitive materials. R. SCHWICKERT Ges. and E. BURG. Brit. 293,347, July 4, 1927. Processes as described in Brit. 284,253 (C. A. 22, 4395) are modified by using as the light-sensitive media compds. produced by the action on diazo or nitroso compds. such as diazotized 1-amino-2-naphthol-4-sulfonic acid, nitrosophenacetin, nitrosophenlactin, or aminophenol substituted by succinic acid, of alkali or alk. earth salts of aliphatic and oxyacids, aromatic carboxylic acids or sulfo acids, amino acids, etc., such as acetic, succinic, lactic, citric, tartaric, oxalic, benzoic, benzenesulfonic, cinnamic and phenylacetic acids. The products, either alone or with coupling compds., yield on exposure visible pictures which require no development, and if mixed with a small quantity of alkali and coupling compds. do not couple in the dark. They yield positive pictures directly; but if given a short exposure in the presence of coupling compds. and alkali in small quantity yield negative pictures. Various details and examples are given. Cf. C. A. 23, 783.

Photographic films of cellulose acetate composition. L. WĘSTRON. Brit. 293,269, Jan. 5, 1928. In order to prevent shrinking or crinkling in the developing or other baths of films contg. cellulose acetate together with aryl phosphates, aryl ethers or ales (and which may also contain NH_3 compds. and glycerol esters) the film base is treated for 6 hrs. or longer (and before it is coated with sensitive emulsion) with water at a temp. not exceeding 70° (suitably for 12–48 hrs. at 30 – 50°). The process may be accelerated by the addn. of a small quantity of an alkali such as NH_3 or an amido or amino compd. such as trimethylamine, aniline, acetamide, phenylacetamide, urea, pyridine, $(\text{CH}_3)_3\text{N}_4$ or benzidine.

Photographic paper. GEORG ENGELMANN. Ger. 470,519, June 9, 1927. Tissue paper is secured to a paper support by means of starch and made sensitive to light in the usual way. The tissue paper adheres to its support during developing and fixing, but can be detached after drying and a very thin picture so obtained.

Printing photographic gelatin layers. I. G. FARBENIND. A.-G. (Hermann Lummerzheim and Eduard Schnitzler, inventors). Ger. 470,618, Jan. 28, 1928. An aq. soln. of a dye is used to which a hardening agent for gelatin is added. The soln. may contain also a wetting agent, e. g., $\text{PhCH}_2\text{COONa}$ or saponin, and a lyophile colloid. According to one example, a soln. of "para-alkali blue" in 40% CH_2O soln. gives an impression which becomes water-resistant after some days and hence can be used for writing on crude cinematograph films. An aq. soln. of "para-alkali blue" and $\text{K}_2\text{Cr}_2\text{O}_7$ is also suitable.

Producing photographic records on sensitive surfaces by use of varying corona discharges. AUSTIN G. COOLEY (49% to Charles C. Henry). U. S. 1,702,595, Feb. 19.

Arc carbons for photographic use. COMPAGNIE LORRAINE DE CHARBONS LAMPES ET APPAREILLAGES ELECTRIQUES. Fr. 644,197, Apr. 21, 1927. Substances such as Si, B, Zr, V or carbides of these metals, with rare earths of the Ce group or with alkalies are incorporated in the arc carbons to give the max. stability to the arc flames.

Photometallization. PIERRE GIGUET and FRANÇOIS GIGUET. Fr. 644,463, Nov. 25, 1927. In metallization the reserves necessary to limit the deposition to desired parts is obtained photographically. Thus, a metal plate is coated with dichromate paste, then placed under a photographic positive and exposed to a suitable source of light. The plate is developed, washed and dried and placed in the electrolytic bath.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Indophenol reaction in inorganic chemistry. J. STIEPOVICH AND A. SA. *Rev. Cent. Estud. Farm. Bioquim.* 16, 384-5(1927).—In the indophenol test for Cl the production of hypochlorite is necessary, Na or K hydroxide or carbonate, but not hydrogen carbonate, being added. Carbonate can be detected in a diln. of 1 in 5000. Tertiary phosphates yield indophenol-blue immediately in the cold; secondary phosphates react slowly in the cold but rapidly on warming, while primary phosphates do not react.

B. C. A.

Chlorides of ruthenium. $\text{Ru}(\text{OH})\text{Cl}_2$, RuCl_3 and RuCl_4 . H. REMY AND A. LÜTHRS. *Ber.* 62B, 200-9(1929); cf. *C. A.* 22, 2521; 23, 352.— RuO_4 reacts with concd. HCl with the formation of RuO_2Cl_2 . This is further reduced by excess HCl to RuCl_4 . The latter is not stable and decomposes according to the circumstances into RuCl_3 and free Cl_2 , or into $\text{Ru}(\text{OH})\text{Cl}_2$ by hydrolysis. Before the hydrolysis is finished, it is possible, by passing through an indifferent gas, to obtain reduction to R^{++} . The reduction stops at the 4th stage when the Cl_2 is taken away after the hydrolysis. The valence was estd. according to the method of Howe (cf. *C. A.* 21, 3851).

E. SCHOTTE

Boron hydrides. XII. $\text{B}_{10}\text{H}_{14}$. A. STOCK AND E. POHLAND. *Inst. Tech. Karlsruhe.* *Ber.* 62B, 90-9(1929); cf. *C. A.* 21, 541.— $\text{B}_{10}\text{H}_{14}$ is a by-product of the prepn. of B_2H_6 on the heating of B_4H_{10} . It m. $99.6-99.7^\circ$, b. 213° . The vapor pressure is expressed by $\log p = -(3218.5/T) + 1.75 \log T - 0.005372 T + 7.4106$. d_4 (solid) = 0.92, d_{100} (liquid) = 0.78. Its gas d. indicates a mol. wt. of 122.9. Heating for 24 hrs. at 250° gives decompn. into H_2 and B_{10}H_6 . By heating with about 1% H_2O for 15 hrs. at 100° in an evacuated tube, H_2 and a yellow soln. are obtained. Evapn. at room temp. of this soln. gives a stable compd. which reduces KMnO_4 but not Cu and Ni soln. On acidifying, the yellow color disappears with H_2 evolution. Air and O_2 do not affect $\text{B}_{10}\text{H}_{14}$ at $50-60^\circ$. Heating in a closed tube at 100° with O_2 gives an explosion. $\text{B}_{10}\text{H}_{14}$ is insol. in H_2O but sol. in NaOH . $\text{B}_{10}\text{H}_{14}$ combines with about 6NH_3 at low temp. but this is given off at room temp. Heating with NH_3 causes evolution of H_2 without formation of $\text{B}_2\text{N}_2\text{H}_6$; different complex compds. are formed, varying with the temp. The compds. are electrolytes. HCl does not react with the hydride but I is easily substituted. $\text{B}_{10}\text{H}_{12}\text{I}_2$ is sol. in H_2O and in NaOH with H_2 evolution.

E. SCHOTTE

Arsenides of magnesium and zinc. G. NATTA AND L. PASSERINI. *Reale politecnico, Milano.* *Gazz. chim. ital.* 58, 541-50(1928).—The lack of knowledge of the chemistry, particularly the lattice structure, of binary compds. of metalloids of the 5th group and metals of the 2nd group induced the authors to undertake a systematic study by means of x-rays of these compds. to det. the *isomorphic and morphotropic relations of N, P, As and Sb*. The present paper deals only with Mg_3As_2 and Zn_3As_2 . Mg arsenide was prepd. by heating Mg and a slight excess of As out of contact of air. Thus prepd. it was gray with a metallic aspect, fragile, microcryst., d. 3.165, and m. 800° . Analysis showed Mg_3As_2 . Zn arsenide was prepd. by heating the calcd. proportions of Zn and As at 800° out of contact of air, under which conditions it was a compact but fragile mass with conchoid fracture and d. 5.578. Analysis showed Zn_3As_2 . Both Mg_3As_2 and Zn_3As_2 were examd. with x-rays by the powder method, radiation from a Philips electron tube and a Cu anticathode being used. Each has a cubic lattice contg. 2 mol. of Me_3As_2 in the elementary cell. Zn_3As_2 has an elementary cell with $a = 5.81$ A. U. and a calcd. d. of 5.854 and Mg_3As_2 has an elementary cell with $a = 6.10$ A. U. and a calcd. d. of 3.26. The arrangement of the atoms in the lattice of Mg_3As_2 and of Zn_3As_2 represents a *new type of lattice structure*, which is defined by the coördinates: As = $(\frac{1}{4}, \frac{1}{4}, \frac{1}{4})$; $(\frac{3}{4}, \frac{3}{4}, \frac{3}{4})$; $(\frac{1}{4}, \frac{3}{4}, \frac{3}{4})$; $(\frac{3}{4}, \frac{1}{4}, \frac{3}{4})$ and Mg or Zn = $(\frac{1}{2}, 0, 0)$; $(0, \frac{1}{2}, 0)$; $(0, 0, \frac{1}{2})$; $(0, \frac{1}{2}, \frac{1}{2})$; $(\frac{1}{2}, 0, \frac{1}{2})$; $(\frac{1}{2}, \frac{1}{2}, 0)$. distance Mg-Mg is 3.05, that of Zn-Zn is 2.90, that of Zn-As is 2.52, that of As-Mg is 2.64, while that of As-As is 4.11 and 4.31 for Zn_3As_2 and Mg_3As_2 , resp. Based on these data, calcs. show the at. radii of Zn and of Mg to be 1.45 and 1.525 A. U., resp., values which correspond roughly to those of neutral Zn and Mg atoms calcd. from the lattices (1.33 and 1.02 A. U., resp.). From the distances Zn-As and Mg-As and the at. radii, the at. diam. of As is calcd. to be 1.19 and 1.02 A. U., resp., which is close to that of the neutral As atom calcd. by Goldschmidt (1.16 A. U.). The x-ray analysis shows that the structure of the arsenides is non-ionic, a conclusion which is confirmed by a detn. of the heat of formation. The heat of formation of Zn_3As_2 is 30.3 cal. per g.-mol., which is low in comparison with that of blende which

though²contg. only 1 atom of Zn in the mol. has a heat of formation of 43 cal. per g.-mol. C. C. DAVIS

The nitrites of platinum. II. I. I. CHERNYAEV. *Ann. inst. platine* 1927, No. 5, 102-18; *Chem. Zentr.* 1927, II, 1556-7; cf. *C. A.* 21, 2620 and following abstract.—In generalizing the rules given in the previous article C. states that in the complex compds. of Pt the stability of the union of a mol. or radical linked in a coordinative way may be weakened by the NO₂ group being in the *trans*-position; other acid radicals exert a weaker "*trans*-effect." This rule explains a series of reactions, which have been verified by C. Thus K₂PtCl₄ and K₂Pt(NO₂)₄ in H₂O give I, because after Cl has substituted the 1st NO₂ group in K₂Pt(NO₂)₄, the 2nd and 4th NO₂ groups are linked more loosely than the 3rd one. If it is assumed, however, that Cl in K₂PtCl₄ is replaced by NO₂, *trans*-K₂[Pt(NO₂)₂Cl₂] has first to be formed; then 2 mols. of *trans*-K₂[Pt(NO₂)₂Cl₂] will give 2 mols. of *cis*-K₂[Pt(NO₂)₂Cl₂]. Likewise *trans*-[Pt(NH₃)₂Cl₂] and *trans*-[Pt(NH₃)₂(NO₂)₂] in H₂O will yield *trans*-K₂[Pt(NH₃)₂Cl(NO₂)]; *trans*-[Pt(NO₂)₂(NH₃)Py] and *trans*-[PtCl₂(NH₃)Py] will give II (Py = pyridine). The displacement of a *cis*-group proceeds slowly; thus to complete the reaction: *cis*-[Pt(NH₃)₂(NO₂)₂] + *cis*-[Pt(NH₃)₂Cl₂] = 2 *cis*-[Pt(NH₃)₂Cl(NO₂)] heating for 10 hrs. on the waterbath is required. The compd. *cis*-[Pt(NH₃)₂Cl(NO₂)] may be cryst. from aq. NH₃, pyridine, H₂NCH₂CH₂NH₂, etc.; with AgNO₃ it becomes turbid only very slowly. Triamines of the quadrivalent Pt may be prep'd. from the corresponding triamines of the bivalent Pt in 2 ways: 2[A₁A₂A₃Pt(NO₂)]NO₂ + 8HCl = 2[A₁A₂A₃Pt(NO₂)Cl₂]Cl + N₂ + Cl₂ + 4H₂O, or: [A₁A₂A₃Pt(NO₂)Cl]Cl + Cl₂ = [A₁A₂A₃Pt(NO₂)Cl₂]Cl. Thus were obtained: [Pt(NH₃)₃(NO₂)Cl₂]Cl (yellowish plates), [Pt(NH₃)₃Py(NO₂)Cl₂]Cl (white needles), [Pt(NH₃)₃(H₃CNH₂)Py(NO₂)Cl₂]Cl (greenish yellow plates) and [Pt(NH₃)₃(EtNH₂)Py(NO₂)Cl₂]Cl (greenish yellow plates), in which the "Cl" in the inner sphere are always situated in *trans*-position to each other, with NH₃ or amines in *cis*-position. One of these Cl atoms may be replaced by the NO₂ group by means of NaNO₂. Under the influence of alkali, these compds. lose 1 mol. HCl. Thus the compds [A₁A₂Pt(NH₃)₂(NO₂)₂Cl₂] or [A₁A₂Pt(NH₃)₂(NO₂)₂Cl], resp., are formed, which with HCl will give the original salts. The expected compd. [Pt(NH₃)₂(NH₂)₂(NO₂)Cl₂] could not be isolated because it is probable that simultaneously the compd. [Pt(NH₃)₃(NO₂)Cl₂]OH was formed. In the compd. [Pt(NH₃)₃(NO₂)Cl₂]Cl reacting with NH₃, the activation of Cl caused by the Cl in *trans*-position gives rise to formation of [Pt(NH₃)₄(NO₂)Cl]Cl₂ even in the cold. This latter salt is converted into the greenish yellow [(NH₃)₄Pt(NH₂)(NO₂)Cl]Cl upon addn. of more NH₃ or alkali. Since in the compd. [Pt(NH₃)₄(NO₂)Cl]Cl₂ the inner Cl is situated opposite the NH₃, it is not exchanged for NH₃. The transition [Pt(NH₃)₄(NO₂)Cl]Cl₂ → [Pt(NH₃)₃(NH₂)(NO₂)Cl]Cl is entirely analogous to the transition MeNH₃Cl → MeNH₂ and therefore could be explained by the older structural theories (Jørgensen), but it does not follow from Werner's theory. C. did not succeed in splitting the salts of the cations [Pt(NH₂OH)Py(NH₃)(NO₂)]⁺ and [Pt(MeNH₂)Py(NH₃)(NO₂)]⁺ into optically active isomers, which agrees with the assumption that the coordinated radicals lie in a plane. The following salts were synthesized: *cis*-[PtPy₂(NO₂)(NH₃)₂(PtCl₄)] salt III (m about 100° (decompn.)) and salt IV (rose-colored plates). Since in contrast to salt V and similar salts, salt IV does not contain a ring structure, it is split by 10% HCl, while V is resistant towards HCl of all concns.

G. SCHWOCH

Platinum nitrites. III. I. I. CHERNYAEV. *Ann. inst. platine* 6, 23-39 (1928); cf. *C. A.* 21, 2620.—*cis*-Nitritochloroplatinates of the general type [A₂PtNO₂Cl]⁺ produced by the action of NH₃ or ethylenediamine on K₂[PtCl₂NO₂], ob-

tained by the action of NaNO_2 on K chloroplatinite. The complex $[\text{en PtClNO}_2]$ yields on treatment with excess of NH_3 the base $[\text{en NH}_3\text{PtNO}_2]\text{Cl}$, which with HCl gives the base $[\text{en NH}_3\text{PtCl}_3]\text{Cl}$, which reacts with alkali hydroxides to produce the amide $[\text{en NH}_2\text{PtCl}_3]$. Where pyridine is substituted for NH_3 in the above series of reactions, the trichlorotriammine base $[\text{en C}_5\text{H}_5\text{NPtCl}_3]\text{Cl} \cdot 2\text{H}_2\text{O}$ is produced, which with dil. alkalis yields $[\text{en C}_5\text{H}_5\text{NPtCl}_3]\text{OH}$; this, when dried at 140° , loses a mol. of water to form the imide $[\text{NH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{NH} : (\text{C}_5\text{H}_5\text{N})\text{PtCl}_3] \cdot \text{H}_2\text{O}$. The substance $[\text{en C}_5\text{H}_5\text{NPtNO}_2]\text{Cl}$ reacts in soln. with Cl to yield $[\text{en C}_5\text{H}_5\text{NPtNO}_2\text{Cl}_2]\text{Cl}$, from which $[\text{en} (\text{C}_5\text{H}_5\text{N})(\text{NO}_2)_2\text{ClPt}]\text{Cl} \cdot 2\text{H}_2\text{O}$ is derived by the action of NaNO_2 , and this product again yields with 25% NH_3 $[\text{en} (\text{C}_5\text{H}_5\text{N})(\text{NO}_2)_2\text{ClPt}]\text{OH}$. NH_3 substitutes only one Cl atom of $[\text{en C}_5\text{H}_5\text{NPtNO}_2\text{Cl}_2]\text{Cl}$, the product being $[\text{en C}_5\text{H}_5\text{N} \cdot \text{PtNH}_2\text{NO}_2\text{Cl}]\text{Cl} \cdot 2\text{H}_2\text{O}$, readily convertible into $[\text{en C}_5\text{H}_5\text{NNH}_3\text{PtNO}_2\text{Cl}]\text{Cl}$ by the action of HCl. The *cis*-tetrammines yield Cleve's salt on reduction to bivalent Pt. The tetrammine $[\text{en} (\text{NH}_3)_4\text{PtNO}_2\text{Cl}]\text{Cl}_2$ is sepd. into its optical antipodes, for which $[\text{M}]_D$ is -137° and $+145^\circ$, resp. Two stereoisomerides of $[\text{en C}_5\text{H}_5\text{NPtNO}_2\text{Cl}_2]\text{Cl}$ are prepd. and 3 of $[\text{en NH}_3\text{PtNO}_2\text{Cl}_2]\text{Cl}$. When quadrivalent is reduced to bivalent Pt in these complexes, the 2 substituent groups which are attached to one coordinate are invariably eliminated. IV. *Ibid* 55-97.—The following nonelectrolytic nitrates

of bivalent Pt have been prepd.: dinitrodihydroxylaminoplatinum,
$$\begin{array}{c} \text{NO}_2 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{Hx} \end{array} \begin{array}{c} \text{Hx} \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NO}_2 \end{array} \quad (\text{Hx} =$$

NH_2OH), its stereoisomeride
$$\begin{array}{c} \text{Hx} \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{Hx} \end{array} \begin{array}{c} \text{NO}_2 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NO}_2 \end{array}, \text{dinitroplatinumdiammine}, \begin{array}{c} \text{NO}_2 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NH}_3 \end{array} \begin{array}{c} \text{NH}_2 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NO}_2 \end{array},$$

$$\begin{array}{c} \text{Hx} \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NO}_2 \end{array} \begin{array}{c} \text{Hx} \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NO}_2 \end{array} \quad \text{PtCl}_4 \cdot 2\text{H}_2\text{O}$$
 and
$$\begin{array}{c} \text{NH}_3 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{C}_5\text{H}_5\text{N} \end{array} \begin{array}{c} \text{Hx} \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NO}_2 \end{array} \quad \text{PtCl}_4$$
 and amminopyridinomethylaminonitroplatinum chloroplatinite. The complex
$$\begin{array}{c} \text{NH}_3 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NO}_2 \end{array} \begin{array}{c} \text{NH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{NH}_2 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NH}_3 \end{array}$$

$$\begin{array}{c} \text{NH}_3 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NO}_2 \end{array} \begin{array}{c} \text{NH}_2 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NO}_2 \end{array} \quad \text{PtCl}_4$$
 is obtained by the interaction of the complex
$$\begin{array}{c} \text{NH}_3 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NO}_2 \end{array} \begin{array}{c} \text{NH}_2 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{Cl} \end{array}$$
 with

mol. of ethylenediamine and the addn. of K chloroplatinite. The complex
$$\begin{array}{c} \text{Hx} \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NO}_2 \end{array} \begin{array}{c} \text{NH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{NH}_2 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NH}_3 \end{array} \quad \text{PtCl}_4$$
 is obtained in an analogous way

from
$$\begin{array}{c} \text{NO}_2 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{Hx} \end{array} \begin{array}{c} \text{NH}_3 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{Cl} \end{array}$$
 and the following complexes are prepd. similarly:
$$\begin{array}{c} \text{NH}_3 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NO}_2 \end{array} \begin{array}{c} \text{NH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{NH}_2 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NH}_3 \end{array} \quad \text{PtCl}_4$$
,
$$\begin{array}{c} \text{NH}_3 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NO}_2 \end{array} \begin{array}{c} \text{NH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{NH}_2 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{Hx} \end{array} \quad \text{PtCl}_4$$
 and

$$\begin{array}{c} \text{NH}_3 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NO}_2 \end{array} \begin{array}{c} \text{NH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{NH}_2 \\ \diagup \\ \text{Pt} \\ \diagdown \\ \text{NO}_2 \end{array} \quad \text{SO}_4$$
. Formula indicating the space orientation

of quadrivalent Pt bases are written $[\text{ABCDEFPt}]$, where A to F represents groups substituted within the octahedron in the order shown in formulas (I) and (II), the latter applying to ring derivs. contg. ethylenediamine. The following nonelectrolytic

derivs. of quadrivalent Pt are prepd. and described: *nitrotrichloroplatinumdiammine*, $[\text{NH}_2\text{CINH}_2\text{NO}_2\text{Cl}_2\text{Pt}]$, *pyridinonitrotrichloroplatinumammine*, $[\text{C}_5\text{H}_5\text{NNH}_2\text{NO}_2\text{Cl}_2\text{Pt}]$, and *ethylenediaminonitrotrichloroplatinum*, $[\text{en NO}_2\text{Cl}_2\text{Pt}]$. The following electrolytic quadrivalent Pt derivs. are prepd. and described: *triamminonitrodichloroplatinum chloride*, $[(\text{NH}_3)_3\text{NO}_2\text{Cl}_2\text{Pt}]\text{Cl}$, *triamminodinitrochloroplatinum chloride*, $[(\text{NH}_3)_3(\text{NO}_2)_2\text{ClPt}]\text{Cl}$, *diamminopyridinonitrodichloroplatinum chloride*, $[\text{C}_5\text{H}_5\text{NNH}_2\text{NO}_2\text{NH}_2\text{ClPt}]\text{Cl}$, optically active *diamminopyridinodinitrochloroplatinum chloride*, $[\text{C}_5\text{H}_5\text{NNH}_2\text{NO}_2\text{NH}_2\text{NO}_2\text{ClPt}]\text{Cl}$, *amminopyridinomethylaminodichloroplatinumammine chloride*, $[\text{C}_5\text{H}_5\text{NNH}_2\text{NH}_2\text{MeNO}_2\text{Cl}_2\text{Pt}]\text{Cl}$, optically active *amminopyridinomethylaminodinitrochloroplatinum chloride*, $[\text{C}_5\text{H}_5\text{NNH}_2\text{NH}_2\text{MeNO}_2\text{NO}_2\text{ClPt}]\text{Cl}$, *ethylenediaminopyridinonitrodichloroplatinum chloride*, $[\text{en C}_5\text{H}_5\text{NNO}_2\text{Cl}_2\text{Pt}]\text{Cl}$, its dextrorotatory stereoisomeride, $[\text{en C}_5\text{H}_5\text{NCINO}_2\text{ClPt}]\text{Cl} \cdot 2\text{H}_2\text{O}$, *d-ethylenediaminopyridinodinitrochloroplatinum chloride*, $[\text{en C}_5\text{H}_5\text{NNO}_2\text{ClNO}_2\text{Pt}]\text{Cl} \cdot 2\text{H}_2\text{O}$, *ethylenediaminopyridinotrichloroplatinum chloride*, $[\text{en C}_5\text{H}_5\text{NCl}_3\text{Pt}]\text{Cl}$, *amminothylenediaminonitrodichloroplatinum chloride*, $[\text{en NO}_2\text{NH}_2\text{Cl}_2\text{Pt}]\text{Cl}$, its *d*- and *l*-isomerides, $[\text{en NH}_2\text{ClNO}_2\text{ClPt}]\text{Cl}$ and $[\text{en NO}_2\text{ClNH}_2\text{ClPt}]\text{Cl} \cdot \text{H}_2\text{O}$, *amminoethylenediaminotrichloroplatinum chloride*, $[\text{en NH}_2\text{Cl}_3\text{Pt}]\text{Cl}$, *tetramminonitrochloroplatinum chloride*, $[(\text{NH}_3)_4\text{NO}_2\text{CINH}_2\text{Pt}]\text{Cl}$, optically active *triamminopyridinonitrochloroplatinum chloride*, $[\text{NH}_3\text{C}_5\text{H}_5\text{NNH}_2\text{NO}_2\text{NH}_2\text{ClPt}]\text{Cl} \cdot \text{H}_2\text{O}$, *l-diamminoethylenediaminodichloroplatinum chloride*, $[\text{en NH}_2\text{CINH}_2\text{ClPt}]\text{Cl}$, *l-diamminoethylenediaminonitrochloroplatinum chloride*, $[\text{en NH}_2\text{NO}_2\text{NH}_2\text{ClPt}]\text{Cl}$, optically active *amminoethylenediaminopyridinodichloroplatinum chloride*, $[\text{en C}_5\text{H}_5\text{NCINH}_2\text{ClPt}]\text{Cl} \cdot \text{H}_2\text{O}$, and optically active *amminoethylenediaminopyridinonitrochloroplatinum chloride*, $[\text{en C}_5\text{H}_5\text{NNO}_2\text{NH}_2\text{ClPt}]\text{Cl}$.

B. C. A.

Vanadium compounds and boiling sulfuric acid. A. SIEVERTS AND E. L. MÜLLER. *Z. anorg. allgem. Chem.* 173, 313–23 (1928).—Boiling concd. H_2SO_4 effects partial reduction of V_2O_5 to vanadyl sulfate and partial oxidation of vanadyl sulfate to V_2O_5 . If more than 0.12 g. of V per 100 cc. of acid is present, the salt, VOSO_4 , seps. (cf. Auger, *C. A.* 16, 31). In the presence of $(\text{NH}_4)_2\text{SO}_4$ both quinquevalent and quadrivalent V are completely reduced to the tervalent state by boiling concd. H_2SO_4 and the salt, $\text{NH}_4\text{V}^{III}(\text{SO}_4)_2$, seps. (cf. Rosenheim and Mong, *C. A.* 20, 2626). H_2SO_4 and K_2SO_4 decompose vanadyl sulfate into equimol. proportions of vanadic acid and the salt, $\text{KV}^{III}(\text{SO}_4)_2$ (cf. Eichner, *C. A.* 22, 550).

B. C. A.

Pseudo halogens. III. Tricyanomethyl and bromine tricyanomethylide. L. BIRKENBACH AND K. HUTTNER. *Ber.* 62B, 153–63 (1929); cf. *C. A.* 20, 345.— $\text{BrC}(\text{CN})_3$ is prepd. from $\text{AgC}(\text{CN})_3$ by treating at -10° with Br_2 in abs. Et_2O . *Silver tricyanomethylide* is obtained by treating disodium malononitrile with BrCN in alc. soln. The alc. is distd. off and the residue taken up with Et_2O to remove impurities. Further discoloration is obtained by treating the aq. soln. with charcoal. With NH_4OH and AgNO_3 the bromide is taken away. The filtrate contg. $\text{NaC}(\text{CN})_3$ acidified with HNO_3 gives $\text{AgC}(\text{CN})_3$ after the addn. of AgNO_3 . After dissolving in concd. NH_4OH and filtering, HNO_3 is added. A white salt is formed, which is stable to light. The nomenclature is discussed; $\text{HC}(\text{CN})_3$ is called *hydrogen tricyanomethylide* and the H_2O soln., *hydrotricyanomethylidic acid*. The degree of dissocn. is about equal to that of the halogen acids. $\text{BrC}(\text{CN})_3$ has oxidizing action. The $\text{C}(\text{CN})_3$ group is more electronegative than the Br part. $\text{BrC}(\text{CN})_3$ is sol. in most solvents. At 68° it changes from white to yellow-red and melts at 72° with decompn. to a red liquid. The cond. of the microbenzene soln. is detd.

E. SCHOTTE

Optical activity of platinum. I. I. CHERNYAEV. *Ann. inst. platine* 6, 40–55 (1928).—Two of the stereoisomerides of the complex $[\text{en NH}_2\text{PtCl}_2\text{NO}_2]\text{Cl}$ are resolved into optical antipodes, as are the complexes $[\text{en C}_5\text{H}_5\text{NPtNO}_2\text{Cl}_2]\text{OH}$ and $[\text{en}(\text{NH}_3)_2\text{PtCl}_2]\text{Cl}_2$. Stereoisomerism has a profound influence on the magnitude of the rotatory power and of the dispersion coeff. The application of the amino reaction, leading to the production of $[\text{en NH}_2\text{PtNO}_2\text{Cl}_2]$, brings about a change of sign of rotation, the appearance or the enhancement of Cotton's effect, and an increase in the abs. value of mol. rotation. The inversion of rotation takes place with ionic velocity and is completely reversible and the same applies to that of triamines and tetramines. *trans*-Trichlorotriamines react with ammonia to form *cis*-dichlorotetramines. Inversion of optical rotation is brought about by alkalis only in those complexes into the nucleus of which NH_3 enters.

B. C. A.

Reduction of dichromate to basic chromic salts. G. GRASSER AND T. NAGAHAMA. *J. Faculty Agr. Hokkaido Imp. Univ.* 24, No. 1, 25-38(1928). (In German).—Portions of $K_2Cr_2O_7$ soln. were boiled with 12 reducing agents without acid. Solns. were subjected to perchromate test for chromate, pos. tests indicating incomplete reduction. None of the agents tested gave complete reduction without acid. The amts. of H_2SO_4 , HCl , $AcOH$ and $HCOOH$ necessary to effect complete reduction with each agent were similarly detd. Of the acids, HCl was much more effective than $AcOH$ or $HCOOH$, and of the reducing agents, tartaric and lactic acids required the least acid.

H. B. MERRILL

Reactions of alkaline molybdates on malic and tartaric esters. F. DARMON. *Faculte de Sci., Paris. Bull. soc. chim.* 43, 1214-29(1928).—The reactions of molybdates on Et malate were studied at 80° and the rotation was studied as a function of time and concn. With MoO_3 and varying amts. of $NaOH$ the mutarotation increases until the soln. contains $MoO_3 + 2NaOH$, and then with more $NaOH$ it becomes less rapid. With the mixt. $2NH_4HMoO_4 + C_4H_4O_6(C_2H_5)_2$ sapon. takes place with the formation of a levorotatory complex and then complete decompn. of the malate with the formation of a dextrorotatory salt, showing the reaction to take place in 2 steps. With Na_2MoO_4 the complexes formed are of the type $MoO_3 \cdot 2C_4H_4O_6$. Tartaric acid and tartrates show exactly analogous reactions.

E. G. VAN DEN BOSCHE

Reaction between nitrogen peroxide and sulfur dioxide. E. BRINER, G. H. LUNGE AND A. VAN DER WIJK. *Helv. Chim. Acta* 11, 1125-44(1928).—The method for the study of the reaction between N_2O_4 and SO_2 has been elaborated on. In the liquid phase the reaction is: $\frac{1}{2}N_2O_4 + 2SO_2 \rightarrow S_2N_2O_8$ (I) + NO . I behaves as the anhydride of nitrosylsulfuric acid when treated with water, alkali, or SO_2 . It is stable at ordinary temps., but decomposes when heated into S_2NO_7 and N_2O_4 . The reaction between SO_2 and N_2O_4 in liquid forms is exothermic, 112 cal. In the gaseous phase the reaction takes place rather slowly at ordinary temps. and pressures and more rapidly at higher temps. The av. N content of reaction products above 80° is lower than that for I. In the presence of catalysts this reaction is very rapid but not complete.

FRIEDRICK C. HAHN

The molecular weight and constitution of hypophosphoric acid. ARTHUR ROSENHEIM AND HEINZ ZILG. *Z. physik. Chem., Abt. A*, 139, 12-21(1928).—The decomposition of hypophosphoric acid in aq. soln. into H_3PO_3 and H_3PO_4 is catalyzed by H ions. The rate of the hydrolysis corresponds to a monomol. reaction. This indicates that the formula of the acid is $H_4P_2O_6$ rather than $H_2P_2O_6$. This result agrees with the cryoscopic measurements of Cornec (*C. A.* 4, 725), but is contrary to the mol.-wt. detns. of the alkyl hypophosphates by Rosenheim (*C. A.* 4, 2778). A summary of the properties of the acid leads to the conclusion that the valence of the P atoms is 4 and that the formula is best represented by the coordination $[O_3P \dots PO_3]H_4$. Several new compds. of the acid were prepd. in order to study further the analogy between the hypophosphates and the pyrophosphates. These include the new sesquihydrate of the sodium salt, $Na_2P_2O_6 \cdot 1.5H_2O$ (I), the sodium ammonium salt, $Na_2(NH_4)_2P_2O_6 \cdot 7H_2O$ (II), the complex ammonium chromium phosphate, $(NH_4)_3[CrP_2O_6] \cdot 5H_2O$ (III), and the complex Cu and Ni salts, $(NH_4)[CuP_2O_6] \cdot 4H_2O$ (IV) and $Na_2[NiP_2O_6] \cdot 12H_2O$ (V). The transition pt. between I and the decahydrate lies at 74.6° . The electrolysis of solns. of IV and V indicate that the heavy metallic atom is in the anion.

H. F. JOHNSTONE

Synthesis of hypophosphorous acid. T. MILOBEDZKI AND J. WALCZYNSKA. *Poznanski Chem.* 8, 486-500 (501 French)(1928).—The synthesis of the ethyl ester of hypophosphorous acid was based on the following reaction: $(C_2H_5O)_2(O)PCl + NaOP(OC_2H_5)_2 \rightarrow NaCl + (C_2H_5O)_4P_2O_2$ (I) (cf. *C. A.* 21, 2457). The same product, bp. 114° , is obtained by the action of the chlorides of esters of phosphorous acid on the Na salts of esters of phosphoric acid: $(RO)_2(O)PCl + (NaO)OP(OR)_2 \rightarrow NaCl + (RO)_4P_2O_2$. The dissocn. of I gives diethyl phosphite and metaphosphoric acid: $(C_2H_5O)_4P_2O_2 \rightarrow (C_2H_5O)_2POH + HPO_3$. By dissocn. of menthyl hypophosphite menthene is obtained: $(C_{10}H_{19}O)_4P_2O_2 \rightarrow H_4P_2O_6 + 4C_{10}H_{18}$. These reactions lead for the first time to the synthesis of $H_4P_2O_6$.

JAROSLAV KUCERA

A new fluoboric acid. A. TRAVERS AND MALAPRADE. *Compt. rend.* 187, 765-7(1928).— $H_3PO_3 + 4HF$ is neutralized with KOH . The neutralization curve shows that H_3PO_3 reacts instantaneously with HF to form a new fluoboric acid, the salt of which is easily decompd. by alkali. Tetrafluoboric acid, HBF_4 , is then formed slowly, particularly in a cold medium, until equil. between the 2 fluoboric acids is established. The time taken and the amt. of the latter formed at equil. increase with the concn. of the reagents and the initial acidity of the mixt.

ALBERT L. HENNE

Silicic acids. W. DILTHEY AND E. HÖLTERHOFF. Univ. Bonn. *Ber.* 62B, 24–31 (1929).—The reaction $4\text{Ph}_3\text{COH} + \text{SiCl}_4 = 4\text{Ph}_3\text{CCl} + \text{Si(OH)}_4$ was performed in abs. Et_2O at varying temps. with 4.5 mols. of Ph_3COH . The H_2O content of the hydrates obtained ranged from 26.2 to 29.6%, Si(OH)_4 having 37.5% H_2O . With 3 mols. of Ph_3COH a product was obtained with about 1% higher H_2O content than H_2SiO_3 . Drying and rewetting of a product with 27.3% H_2O gave a const. product with about 25% moisture. The H_2O must be bound constitutionally. There is a possibility that H_2O is split off intramol., followed by polymerization of Si(OH)_4 to $(\text{HO})_3\text{SiOSi(OH)}_3 \rightarrow (\text{HO})_3\text{SiOSi(OH)}_2\text{OSi(OH)}_3 \rightarrow (\text{HO})_3\text{SiO}[\text{Si(OH)}_2]_n\text{OSi(OH)}_3$. For $n = 4$ the H_2O content is 25.1% (cf. C. A. 23, 787). The reaction carried out in different org. media at varying temps. gives varying H_2O contents. V. R. SCHWARZ AND H. RICHTER. *Ibid.* 31–6; cf. C. A. 22, 4028.—The gels from SiCl_4 made at 0° and dehydrated with org. liquids and liquid NH_3 (cf. C. A. 22, 3365) contain the hydrate $\text{SiO}_2 \cdot \text{H}_2\text{O}$. With liquid NH_3 the hydrate seems to undergo a partial dehydration. On raising the working temp. to 100° , hydrates with lower H_2O content were obtained. E. SCHOTTE

Per-acids of uranium, tantalum and niobium. A. SIEVERTS AND E. L. MÜLLER. *Z. anorg. allgem. Chem.* 173, 297–312 (1928).—Peruranic acid may be prepd. either by addn. of excess of 3% H_2O_2 soln. to a soln. of uranyl nitrate or by treating UO_3 with H_2O_2 . Pertantallic and pernibic acids are obtained by treating the corresponding K salts in concd. aq. soln. with the requisite quantity of H_2SO_4 . The acids are finely divided white and yellow powders, resp., contg. one atom of active O to one atom of metal. Both tantalic and niobic acids dissolve in 3% H_2O_2 , forming opalescent solns.; pertantallic acid is pptd. by alc. or NaCl from the soln. but pernibic acid cannot be isolated thus. B. C. A.

Spectrochemical studies on complex formations between mercuric salts and other metallic salts in dilute aqueous solutions. II. TOSHI INOUE. Tokyo Imp. Univ. *Japan J. Chem.* 3, 147–63 (1928); cf. C. A. 16, 2075, 3588; 17, 2217; 22, 1741.—The max. points in the absorption curves given by dil. solns. (concn. $1/15$ to $3/10$ N, where N denotes normality with respect to the Hg atom in the reaction product) contg. mixts. of Hg(CN)_2 with the chlorides of NH_4 , Na, K, Mg, Cd, Ca, Sr, Ba, Mn, Co and La indicate that the complex ion $[\text{Hg(CN)}_2\text{Cl}]^-$ may exist in aq. soln. Hg(CN)_2 in mixts. with the bromides of NH_4 , Na, K, Ca, Sr and Ba (concn. of soln.-mixts. $1/10$ to $1/2$ N) forms the complex ion $[\text{Hg(CN)}_2\text{Br}_2]^{--}$. With the thiocyanates of NH_4 , Na, K, Ca, Ba and Mg and in soln.-mixts. of concn. $1/10$ to $1/300$ N, the complex ion formed is $[\text{Hg(CN)}_2(\text{SCN})_2]^{--}$. In mixts. of dil. solns. of Hg(CN)_2 with the iodides of Na, K, Ca and Ba the complex ion $[\text{Hg(CN)}_2\text{I}_2]^{--}$ is produced, which on standing changes to $[\text{HgI}_4]^{--}$. With ZnI_2 and CdI_2 the ion $[\text{HgI}_4]^{--}$ is formed directly. Spectrochemical studies on the systems Hg(CN)_2 , $\text{K}_2\text{S}_2\text{O}_8$ and Hg(CN)_2 - AcONa in 0.1 M soln. show the existence of the complex salts $[\text{Hg(CN)}_2\text{S}_2\text{O}_8]\text{K}_2$ (Fock and Krüss, *Ber.* 24, 1355 (1891)) and $[\text{Hg(CN)}_2(\text{AcO})]\text{Na}$. LOUISE KELLEY

Spectrochemical studies on complex formations between mercuric salts and other metallic salts in dilute aqueous solutions. I. TOSHI INOUE. Tokyo Imp. Univ. *Japan J. Chem.* 3, 131–46 (1928).—See C. A. 22, 1741. LOUISE KELLEY

A spectroscopic method of studying the formation of complex salts in dilute solution. II. YUJI SHIBATA AND TOSHI INOUE. Tokyo Imp. Univ. *Japan J. Chem.* 2, 109–15 (1926); cf. C. A. 16, 2075, 3588; 17, 2217; 22, 1741.—Making use of the method described previously, S. and I. have studied the formation of complex salts in dil. soln. Stable in 0.005 M soln. were HgCl_2 - LiCl (1:1); HgCl_2 - NaCl (1:1); HgCl_2 - KCl (1:1); HgCl_2 - NH_4Cl (1:1); HgCl_2 - NaBr (1:1). Stable in 0.0025 M soln. were HgCl_2 - MgCl_2 (1:1); HgCl_2 - SrCl_2 (1:1); HgCl_2 - BaCl_2 (1:1); HgCl_2 - CoCl_2 (1:1). Stable in 0.002 M soln. were HgCl_2 - AlCl_3 (1:1); HgCl_2 - $[\text{Co(NH}_3)_6\text{Cl}_3]$ (1:1). Stable in 0.0005 M soln. were HgCl_2 - KBr (1:4); HgCl_2 - NH_4Br (1:4); HgCl_2 - ZnBr_2 (1:2); HgCl_2 - CdBr_2 (1:2); HgCl_2 - KSCN (1:3); HgCl_2 - Co(SCN)_3 (1:3). Stable in 0.00025 M soln. was HgCl_2 - CdI_2 (1:2). These complex salts are similarly constructed, with Hg as the central metallic atom. The stability of the complex salts which contain HgCl_2 and other metallic chlorides increases with the no. of Cl atoms in the complex radical. The complex salts formed from HgCl_2 and NH_4Cl , CoCl_2 , MgCl_2 and Co(SCN)_3 are more stable in alc. than in aq. solns. LOUISE KELLEY

Spatial arrangement and rotatory dispersion of optically active complex salts of cobalt and rhodium. F. M. JAEGER AND H. B. BLUMENDAL. *Proc. Acad. Sci. Amsterdam* 31, 637–50 (1928).—See C. A. 22, 3596. E. H.

"Titanium cyanonitride" and the titanium oxychlorides. ERNEST A. RUDGE AND FRANCIS ARNALL. *Tech. College, Cardiff. J. Soc. Chem. Ind.* 47, 376–80T (1928).—

The hard Cu-colored crystals found on the masonry of blast furnaces used for smelting Fe and supposed to be Ti cyanonitride ($\text{Ti}(\text{CN})_2 \cdot 3\text{Ti}_3\text{N}_2$) by Wöhler (*Ann. Pharm.* 73, 34(1850)) are found to be TiN in admixt. with C. *Titanium oxychloride*, $3\text{TiCl}_4 \cdot \text{TiO}_2$, is prepd. as yellow crystals by passing Cl_2 (dried over H_2SO_4) over TiN with the introduction of moisture. When Cl_2 is passed over the warmed Cu-colored crystals from the blast furnace, TiN, the yellow crystals and graphite are the products, no "Ti cyanochloride" being formed as supposed by Wöhler. J. BALOZIAN

Molybdenum selenides and selenomolybdates. E. WENDEHORST. *Z. anorg. allgem. Chem.* 173, 268-72(1928).—From a H_2SO_4 soln. of NH_4 molybdate hydrogen selenide ppts. brownish black Mo triselenide, which dissolves in solns. of alkali hydroxides, selenides and sulfides, giving deep red to brown solns. (cf. Moser and Atynski, *C. A.* 19, 1231). If the acid molybdate soln. is reduced with Zn until it becomes of a deep reddish brown color and is then satd. with H_2Se , dense brownish black leaflets of *dimolybdenum pentaselenide*, Mo_2Se_5 , are pptd. A mixt. of MoO_3 and Se when heated in H to dull redness yields *molybdenum diselenide*, MoSe_2 , in bluish black, glistening leaflets insol. in alkali solns. When a mixt. of K_2CO_3 , Se and MoO_3 is fused above 1200° , and the product leached with water, a residue of dark lead-gray crystals of *molybdenum sesquiselenide*, Mo_2Se_3 , is obtained. Satn. of a soln. of K_2MoO_4 in concd. KOH with H_2Se results in the sepn. of red needles of *K selenomolybdate*, K_2MoSe_4 . The Na salt cannot be prepd. under similar conditions, but the NH_4 salt, $(\text{NH}_4)_2\text{MoSe}_4$, is obtained in glistening, blue crystals from a soln. of molybdic acid in concd. NH_3 . All Se compds. of Mo prepd. in the wet way rapidly decompose on exposure to the air; their prepn. must therefore be carried out in an atm. of N. B. C. A.

Thio salts. VII. Polythiovanadates. L. FERNANDES. *Atti accad. Lincei* 8, 234-8(1928); cf. *C. A.* 22, 3598.—When $(\text{NH}_4)_2\text{VS}_4$ is treated with a strong acid, V_2S_5 is formed; if, however, H_2S is used, the intermediate products, NH_4VS_3 , $[\text{H}_2(\text{VS}_3)_2] \cdot (\text{NH}_4)_4$, analogous to the corresponding O salts are formed. Metathiovanadate, $\text{NH}_4\text{VS} \cdot 2\text{H}_2\text{O}$, is obtained by treating 12 g. of the normal thiovanadate with 5 cc $(\text{NH}_4)_2\text{S}$, and satg. the soln. with H_2S under pressure it is a dark-violet microcryst. product which is collected on a suction filter and washed with EtOH and Et_2O . Guanidine metathiovanadate, $\text{GuVS}_2 \cdot 2\text{H}_2\text{O}$, is obtained from the meta-salt by suspending the latter in a concd. soln. of Gu.HCl. $[\text{H}_2(\text{VS}_3)_2] \cdot (\text{NH}_4)_4 \cdot 18\text{H}_2\text{O}$ is made by satg. a soln. of $(\text{NH}_4)_2\text{VS}_4$ (12 g.) and $(\text{NH}_4)_2\text{S}$ (2 g.) with H_2S under pressure at 0° . The product is washed rapidly with EtOH and Et_2O . This is very unstable and when dry evolves NH_3 with such evolution of heat as to ignite the filter paper. If the above wet crystals are dropped into Gu.HCl soln., $[\text{H}_2(\text{VS}_3)_2] \cdot \text{Gu}_4 \cdot 18\text{H}_2\text{O}$ is formed, which is much more stable than the NH_4 salt. Added to ThCl soln. the salt, $[\text{H}_2(\text{VS}_3)_2] \cdot \text{Th}_4 \cdot 18\text{H}_2\text{O}$, is similarly formed. This product which is a lighter blue than the Gu salt is also much more stable than the NH_4 salt. A. W. CONTIERI

Complex compounds of gold with mercaptanic radicals. II. Residual affinities of chlorauric acid. PRAFULLA CHANDRA RAY AND KSHITISH CHANDRA BOSE-RAY. *J. Indian Chem. Soc.* 5, 527-33(1928).—Chlorauric acid reacts with some org. compds to form complex compds. in which the valence of the Au atom varies from 2 to 5 (cf. *C. A.* 19, 815). Triethylene tetrasulfide and 1,4-dithian also react with Au chloride yielding: (a) $\text{HAuCl}_2(\text{C}_2\text{H}_4\text{S})_2$ or $2\text{AuCl} \cdot \text{HCl}(\text{C}_2\text{H}_4\text{S})_2$, (b) $\text{AuCl}(\text{C}_2\text{H}_4\text{S})_2$, (c) $2(\text{H}) \cdot \text{AuCl}_2 \cdot 3(\text{C}_2\text{H}_4\text{S})_2 \cdot 2\text{H}_2\text{O}$, (d) $\text{KAuCl}_4 \cdot 3[(\text{C}_2\text{H}_4\text{S})_2] \cdot 4\text{H}_2\text{O}$, (e) $(\text{H})\text{KAuCl}_4 \cdot 3[(\text{C}_2\text{H}_4\text{S})_2] \cdot 2\text{H}_2\text{O}$, and (f) $\text{AuCl}(\text{C}_2\text{H}_4\text{S})_2$. When assocd. with metallic chlorides, the dithian seems to be polymerized into triethylene trisulfide. Compound (e) is acidic, dibasic and furnishes 4 ions in aq. soln. When NH_3 acts on (a), compds. having the formulas $\text{Au}_3\text{Cl}_2 \cdot 6\text{NH}_3$ and $\text{AuCl} \cdot \text{NH}_3$ are formed. With NH_4OH (c) produces $\text{Au}(\text{NH}_3)_2 \cdot 1\frac{1}{2}\text{H}_2\text{O}$. All 3 of these NH_3 complexes are explosive. Pyridine replaces the dithian more or less completely. Directions for prepn. of each complex and the analysis on which the compn. is based are given for each compd. F. E. BROWN

Compounds of hexamethylenetetramine with certain salts of silver and other metals and the influence of anionic volume on the capacity for association by the central positive atom. PRIYADARANJAN RAY AND JYOTIRMOY DAS-GUPTA. *J. Indian Chem. Soc.* 5, No. 5, 519-25(1928).—Ephriam believes that increase in vol. of anions increases the capacity of most cations to assoc. with natural mols. like NH_3 and H_2O . But the reverse is the case when one considers assocn. of NH_3 with salts of Ag formed from the anions: F^- , Cl^- , Br^- and I^- ; and with the anions: ClO_3^- , BrO_3^- , IO_3^- , ClO_4^- , BrO_4^- , IO_4^- , MnO_4^- , NO_2^- and NO_3^- . When hexamethylenetetramine is substituted for NH_3 , in all cases except that of AgF and AgCl , increase in vol. of an anion increased the ability of the Ag ion to assoc. with neutral mols. The following compds. were prepd., where B indicates a mol. of hexamethylenetetramine: $3\text{AgCN} \cdot \text{B}$; 2Ag

CNO.B ; 2AgCNS.B ; $\text{AgClO}_4.\text{B}$; $\text{Ag}_2\text{CrO}_4.\text{B}$; $4\text{Ag}_2\text{CrO}_7.5\text{B}.4\text{H}_2\text{O}$; $\text{Ag}_2\text{MoO}_4.2\text{B}.2\text{H}_2\text{O}$; $\text{Ag}_2\text{WO}_4.2\text{B}.2\text{H}_2\text{O}$; $2\text{Ag}_2\text{SO}_4.3\text{B}.6\text{H}_2\text{O}$; $4\text{Ag}_2\text{SO}_4.5\text{B}.13\text{H}_2\text{O}$; and $\text{Ag}_2\text{SeO}_4.2\text{B}.12\text{H}_2\text{O}$. These complexes are generally insol. in H_2O . They may be formed by dissolving the simple salt in concd. NH_4OH solns. and adding a strong soln. of $(\text{CH}_3)_4\text{N}_4$. On heating, NH_3 evaps. and the hexamine complex ppts. The following series was prepd.: $3\text{CuCN}.2\text{B}$; $3\text{Cd}(\text{CN})_2.\text{B}$; $3\text{AgCN}.\text{B}$. Since Ag and Cd have about the same vol. and Cu has a smaller vol., it seems that decrease in vol. of the central atom of a complex increases its capacity to assoc. with mols. These complex amines are: sol. in NH_4OH solns., decompd. by mineral acids with evolution of CH_2O , decompd. by caustic alkalis with the formation of metallic oxides, decompd. by heating, with charring,* and a fishy odor as of amines. With CuCN , $\text{C}_6\text{H}_5\text{CO}_2\text{Ag}$, Ag_2SO_4 and $\text{C}_6\text{H}_5(\text{HCO})_2\text{Ag}$ unstable complexes of undetd. compn. were prepd. Methods for prepn. and analysis, and results of analyses are given. F. E. BROWN

Bi in pharmacy and chemistry (DYSON) 17.

LATIMER, WENDELL M., AND HILDEBRAND, JOEL H: **Reference Book of Inorganic Chemistry**. New York: The Macmillan Co. 442 pp. \$3.75.

7—ANALYTICAL CHEMISTRY

W. T. HALL

Need of and opportunity for precise analysis. STEPHEN POPOFF. *Chem. Bull.* (Chicago) 16, 43-5, 70(1929).—Many interesting points are touched upon in this paper, and among other things the inadequacy of uncalibrated "Class S" weights is pointed out. W. T. H.

Quantitative analysis with the spectrograph. CHARLES C. NITCHE. New Jersey Zinc Co. *Ind. Eng. Chem., Analytical Ed.* 1, 1-7(1929).—The speed, sensitiveness and certainty of spectrographic methods for the detection of small quantities of impurities and minor constituents are pointed out and the general principles discussed upon which quant. spectroscopic measurements are based, with particular reference to methods developed in the labs. of the N. J. Zinc Co. W. T. H.

Elementary centigram analysis. I. Determination of carbon and hydrogen with automatic regulation of combustion. II. Determination of nitrogen. BOGUSLAW BOBRANSKI AND EDWARD SUCHARDA. *Roczniki Chem.* 8, 290-323 (323-4 French) (1928).—The method described for detg. C and H is similar to that described by Pregl. The combustion is carried out in a hard glass tube contg. Ag gauze, $\text{CuO} + \text{PbCrO}_4$, platinized asbestos, Ag gauze, PbO_2 , and Ag gauze. Each layer is sepd. from the successive layer by a small asbestos plug. The platinized asbestos layer is compressed in such a way as to form a plug, by means of which the rate of flow of the tube is regulated. A large contact surface of $\text{CuO} + \text{PbCrO}_4$ is assured by pptg. these substances on pure pumice. The layer of PbO_2 is maintained at the temp. of $190-200^\circ$ by an oil bath. The products of combustion, H_2O and CO_2 , are absorbed in the app. of Blumer (*C. A.* 12, 642). The detn. of N is based also on the principle of microanalysis of Pregl, the app. being modified for larger quantities of substance used. N is collected in an azotometer, the upper part of which, having a vol. of 8 cc., is graduated in 0.02 of cc. After the vol. of N_2 is read, it is necessary, however, to subtract 1.2% as a correction due to the adhesion of potash to the glass. The app. is shown in 9 pictures. J. K.

Chemistry in the service of arsenals and military factories. ARLINDO VIANNA. *Boll. chim. farm.* 68, 7-8(1929).—A method is described for the rapid qual. analysis of steels for Cr, Mn, Si, Mo, W, Co, Al, Ti, V and Ni. G. SCHWOCH

Directions for the preparation of a "universal indicator" for estimating pH over a wide range. I. M. KOLTHOFF. Univ. Minnesota. *Pharm. Weekblad* 66, 67-70 (1929).—Objections to van Urk's universal indicator (*C. A.* 23, 752) are pointed out, e. g., the non-availability of 2 components, α -naphthalphthalein and cresolphthalein, the high concn. of cresolphthalein which causes a pptn. when 1 drop of the indicator is added to 10 cc. of soln., the lack of color contrasts for intervals of 1-2 units of the pH scale, and the absence of definite color changes beyond pH 7. A more satisfactory universal indicator proposed by K. is prepd. by mixing 0.1% solns. of the following: dimethyl yellow 15 cc., methyl red 5 cc., bromothymol blue 20 cc., phenolphthalein 20 cc., and thymolphthalein 20 cc. With 0.1 cc. of this mixt. per 10 cc. of soln., the colors

obtained at various p_H values are: 1.0 rose, 3.0 red orange, 4.0 orange, 5.0 yellow orange, 6.0 lemon yellow, 7.0 yellow green, 8.0 green, 9.0 blue green, 10.0 violet. A. W. D.

Urotropine as a microchemical reagent. I. M. KORENMAN. *Pharm. Zentralhalle* 70, 1-3(1929).—The salts of many of the heavy metals yield with $C_6H_{12}N_4$ cryst. ppts., for the most part sol. in water. This behavior renders possible the employment of urotropine as reagent in the microchem. detection of certain heavy metals. To this end a series of expts. was carried out with salts of Ag, Pb, Hg, Bi, Sn and Sb in connection with a 2% soln. of $C_6H_{12}N_4$, the resulting crystals being examd. microscopically and their forms illustrated. W. O. E.

Preparing a good tartaric acid reagent for the detection of potassium. GUIDO AJON. *Rivista ital. essenze profumi* 11, 6-7(1929).—Slowly mix 50 cc. of 2 *N* tartaric acid, 25 cc. 0.5 *N* NaOH and 25 cc. of 96° alc. Use the clear liquid as reagent. R. S.

Detection of the presence of reducing radicals in the systematic analysis for the acids. L. J. CURTMAN AND W. PLECHNER. College of the City of New York. *Chem. News* 138, 50-1(1929).—To 5 cc. of the neutral soln. add 0.5 cc. of 3 *N* H_2SO_4 and 2 drops of 0.1 *N* $KMnO_4$. Look for a bleaching effect, finally heating. The presence of 1 mg. of arsenite, sulfite, iodide, thiocyanate, nitrite, thiosulfate, sulfide, bromide or ferrocyanide is sufficient to cause bleaching in the cold and on heating 10 mg. of oxalate or tartrate and more than 10 mg. of cyanide will cause bleaching. This test gives an important clue in the qual. analysis of salts. W. T. H.

New methods for determining and separating metals with the aid of *o*-hydroxyquinoline. VII. Determination of iron, manganese, nickel and cobalt. Separation of iron from aluminum, manganese and alkaline earths. Separation of manganese from nickel, zinc and alkaline earths. R. BERG. Univ. Königsberg. *Z. anal. Chem.* 76, 191-204(1929); cf. C. A. 22, 1929.—As reagent either a 3-4% soln. of oxine in alc. or a 4% oxine acetate soln. was used. In the latter case, about 4 g. of oxine were dissolved in 8-10 cc. of AcOH and diluted with water to 100 cc.; this soln. keeps well Fe^{+++} in the presence of even 25% AcOH and NaOAc is pptd. quantitatively as greenish black $Fe(C_9H_7ON)_2$. The ppt. can be weighed after drying at 120° or ignited to Fe_2O_3 . Or, about 0.5 g. of ppt. can be dissolved in 200 cc. of 2 *N* HCl, treated with 10 cc. of 50% H_2PO_4 , oxidized with $KBrO_3$ -KBr soln. in the presence of KI and the excess of Br measured by titration of the displaced I with thiosulfate. Still another method, which is specially good in certain sepns., is to det. by a similar titration the excess of oxine. Mn gives a dull yellow ppt. of $Mn(C_9H_6ON)_2 \cdot 2H_2O$ in neutral or faintly acid solns. The ppt. does not lend itself readily to direct weighing but it can be ignited with oxalic acid. Titration of the excess oxine gives good results. Ni gives a greenish ppt. of $Ni(C_9H_6ON)_2 \cdot 2H_2O$ which becomes anhyd. by drying at 130°. The ppt. is formed in 5-10% AcOH soln. in the presence of AcOH. With Co a similar flesh-colored ppt. is obtained. Fe is sepd. from Al by making the Al ions form a complex with oxalic, malonic, tartaric or salicylic acid, etc. At the proper acid concn. the Fe will ppt. while the Al remains in soln. Thus in 100 cc. of soln. contain contg. 3 g. NH_4OAc , 3-4 g. of NH_4 tartrate and 15-20% AcOH, the pptn. of 0.05 g. of Fe in the presence of 0.10 g. of Al can be accomplished at 50° by the dropwise addn. of oxine acetate to the well stirred soln. After filtering, the excess oxine can be detd. by titration and in an aliquot part the Al can be detd. in faintly ammoniacal soln. by adding oxine as has been previously described. Excellent results were also obtained with malonic acid in place of tartrate. For sepg. Fe from alk. earths, the Fe can be pptd. as has been described and in the filtrate Mg detd. by pptn. with oxine in ammoniacal soln., Ca can be pptd. as oxalate, Sr as sulfate, Ba as sulfate. Similarly Fe can be sepd. from Be. For the sepn. of Fe from Mn, it is best to ppt. the Fe in the cold in 10% AcOH soln. contg. considerable acetate and then ppt. the Mn in ammoniacal soln. The compd. of oxine with Mn is very sensitive to acids and in that respect is very : Thus Mn can be sepd. from Zn or from Ca in much the same way as has been for the sepn. of Mg from Zn and Ca. The Zn forms a in which $p_H < 5$ while Mn requires a higher p_H value.

Utilization of the spectrophotometer in the determination of minute amounts of aluminum. E. W. SCHWARTZ AND RAYMOND M. HANN. *Science* 69, 167-70(1929).—The reaction between aurine tricarboxylic acid and Al^{+++} can be utilized for the detn. of very small quantities of Al and better results obtained with the spectrophotometer than with the colorimeter. Fuller details concerning the method are to be published later. W. T. H.

The volumetric determination of arsenic in the presence of organic substances, halogens and heavy metals. E. SCHULEK AND P. V. VILLECZ. K. Ung. Staatl. Hygien. Inst. Budapest. *Z. anal. Chem.* 76, 81-103(1929).—See C. A. 22, 3488. W. T. H.

Determination of beryllium as pyrophosphate and as anhydrous sulfate. V. ČUPR. *Inst. für anorg. Chem. Brunn. Z. anal. Chem.* **76**, 173-91(1929).—Attempts to det. Be as $\text{Be}_2\text{P}_2\text{O}_7$ by methods recommended for the detn. of Mg, Zn, Mn, etc., were all futile; the results all came out too high. If, however, the soln. is first made alk. to methyl red (p_H 6.3) so that $\text{Be}(\text{OH})_2$ or BeHPO_4 ppts. and then a slight excess of $(\text{NH}_4)_2\text{HPO}_4$ and enough acid added to make the soln. acid to methyl red (p_H 4.2), a normal ppt of BeNH_4PO_4 is obtained which yields the theoretical value for $\text{Be}_2\text{P}_2\text{O}_7$ upon ignition. The following procedure is recommended: To 250 cc. of cold Be^{++} soln. contg. 5-10 g. of NH_4 salt per 0.5 g. of expected $\text{Be}_2\text{P}_2\text{O}_7$, add concd. NH_4OH until the soln. is basic to methyl red. Then add 1-1.3 g. of $(\text{NH}_4)_2\text{HPO}_4$ and make acid to methyl red. Heat on the water bath until the amorphous ppt. of $\text{Be}(\text{OH})_2$ has changed to crvst $\text{BeNH}_4\text{PO}_4 \cdot x\text{H}_2\text{O}$. Cool, decant through a filter, and wash with 1% NH_4NO_3 soln. made alk. to methyl red with NH_4OH . Ignite and weigh. If the soln. contained HPO_4 originally, the ppt. produced by adding NH_4OH at the start will be Be phosphate instead of hydroxide and all that is necessary for the pptn. of a normal BeNH_4PO_4 ppt is to produce the proper concn. of H^+ as outlined above. Expts. were also tried in weighing BeSO_4 as such after heating at 400° and the results were excellent. Be present as salt of a volatile acid can, therefore, be detd. in this form. W. T. H.

Separation of beryllium from aluminum, iron and copper by means of o-hydroxyquinoline. M. NIESSNER. *Tech. Hochschule, Wien. Z. anal. Chem.* **76**, 135-45 (1929). Be does not form a ppt. with this reagent whereas Al, Fe and Cu give characteristic ppts. It is easy, therefore, to det. these cations as described by Berg and then, in the filtrate, the Be can be pptd. by adding NH_4OH and weighed as BeO . W. T. H.

Microtitrimetric determination of bismuth. JOHANN STRAUB. *Univ. Debrecen. Z. anal. Chem.* **76**, 108-12(1929).—The method depends upon the pptn. of BiOI , decompn. of the ppt. with KOH soln., oxidation of the iodide to iodate by Cl_2 , treatment of the KIO soln. with KI and titration of liberated I_2 with $\text{Na}_2\text{S}_2\text{O}_3$ soln. W. T. H.

New rapid method for determining cadmium. G. SPACU AND J. DICK. *Univ. Cluj. Bul. soc. stiinte Cluj* **4**, 241-4(1928).—The method is based on the formation of $[\text{CdPy}_4](\text{SCN})_2$. Use 50-100 cc. of Cd soln.; add 0.5-1 g. NH_4NCS ; boil; add 1 cc. pyridine to the boiling soln.; stir several times; allow to cool completely, filter through a Gooch filter; wash with (5 cc. pyridine + 3 g. NH_4NCS + 1000 cc. H_2O); wash 4-5 times with 25% alc. contg. some pyridine, add NH_4NCS ; wash 2 times with 1 cc. abs. alc. + 1 drop pyridine) and several times with (Et_2O + few drops pyridine). Dry by suction and then in a vacuum desiccator. The results are perfect, except in the presence of NH_4Cl (large amts.) or NH_4OAc (small quantities). It is very important that the Cd soln. should not ppt. at once, when adding pyridine (too concd. soln.), and that the soln. be very hot, since otherwise some $[\text{CdPy}_4](\text{SCN})_2$ will be formed. By long drying *in vacuo*, $[\text{CdPy}_4](\text{SCN})_2$ loses 2 mols. of pyridine. A. L. H.

New method for the volumetric determination of cobalt. G. A. BARBIERI. *Atti accad. Lincei* **8**, 405-8(1928).—When cobaltinitrites are decompd. by NaHCO_3 , NaNO_2 and a carbonate of trivalent Co are formed. On adding KMnO_4 in H_2SO_4 soln. the HNO_2 can be oxidized to HNO_3 and Co^{+++} reduced to Co^{++} so that for each atom of Co, 11 equivs. of KMnO_4 are reduced. To 10 cc. of the slightly acid Co^{++} soln. add 20 cc. of 50% NaNO_2 and 2 cc. of AcOH . Heat to boiling in a covered beaker and add dropwise 25 cc. of 20% KNO_3 soln. After 3-4 hrs. filter, wash with 5% KNO_3 soln. (150-200 cc.) till the wash water does not color KI paper and transfer the ppt. into a 500 cc. beaker. To the filtrate add 2-3 g. NaHCO_3 to ppt. any remaining $[\text{Co}(\text{NO}_2)_6]$, and again filter. To the ppt. add 15-20 g. NaHCO_3 and water and heat on water bath till clear liquid is obtained. Cool, run into dil. H_2SO_4 contg. an excess of 0.1% KMnO_4 through a sepg. funnel, the outlet of which must remain below the surface of the KMnO_4 soln. Then add standard FeSO_4 soln. in excess and finally titrate with KMnO_4 . A. W. CONTIERI

Low's short method for copper, modified. H. F. BRADLEY. *Chemist Analyst* **17**, No. 4, 14(1928).—Correction to C. A. **23**, 54. "Brown fumes" should read *brown oxides of Mn* and "133 cc. of concd. NH_4OH " should read 13 cc. W. T. H.

Effect of various salts on the electrolytic determination of copper. A. JULIARD AND J. LEDRUT. *Univ. Bruxelles. Bull. soc. chim. Belg.* **7**, 377-84(1928).—Traces of KClO_4 and KClO give a high-grade Cu deposit. Less current and time are required to deposit the last Cu traces. Sulfites, persulfates, permanganates, chromates, dichromates, nitrites, fluorides, tartrates and sulfonitric solns. interfere with the electrolysis. A. L. HENNE

The ferric thiocyanate reaction as used for detection of traces of iron in chemical reagents. H. W. VAN URK. *Chem. Lab. Marinehospitaal den Helder. Chem. Weekblad*

25, 703-4(1928).—The accuracy of the ferric thiocyanate reaction as influenced by salts was studied. In com. Na_2SO_4 , at best only 0.0007% Fe^{+++} can be detected. In water, oxidized with HNO_3 , 0.00002% of Fe can be detected in the absence of HCl and 0.000005% with HCl (cf. C. A. 20, 3861). The thiocyanate reaction influenced by salts. *Ibid* 704-6.—The decrease in color intensity of the $\text{Fe}(\text{CNS})_3$ complex in salt soln. is caused by hydrolysis due to lower p_{H} of the soln. Addn. of some HCl brings the color back. Whereas for water the optimal HCl concn. is 4 milliequivalents of HCl per 100 cc., this amt. has to be raised to 2 and 4 cc. for Na_2SO_4 and NaAcO solns., resp. Chlorides and nitrates have no influence on the color; salts of weak acids have considerable influence.

B. J. C. VAN DER HOEVEN

The transmission of light through thiocyanate solutions of iron and bismuth, with respect to the estimation of iron in red lead. H. HEINRICH. *Glastech. Ber.* 5, 351 (1927); *J. Soc. Glass Tech.* 12, 182.—Spectroscopic examn. of a CNS^- soln. contg. 0.5 mg. of Fe_2O_3 and 2.0 mg. of Bi_2O_3 per 100 cc. indicated an optimum deviation of color from that of pure $\text{Fe}(\text{CNS})_3$ with a depth of 14 to 18 mm. Thus although Bi did not interfere with the Fe test in all cases, it was likely to give trouble with dil. Fe solns. from pure red lead samples, and should be previously removed by H_2S or treatment in strong HCl.

H. G.

New gravimetric method for the estimation of lead. I. Purely from its soluble salts. P. N. DAS-GUPTA, G. C. ROY AND K. M. SIL. *J. Indian Chem. Soc.* 5, 657-60(1928).—In slightly alk. soln. H_2O_2 ppts. Pb as $\text{Pb}_3\text{O}_4 \cdot 3\text{H}_2\text{O}$ and the ppt. can be heated to 180° without decompn. To the neutral soln. of Pb acetate or nitrate, add 2 drops of dil. HNO_3 or HOAc , dil. considerably and, for 0.1 g. of Pb, add 2 cc. of 3% H_2O_2 . Stir and finally add 2 cc. of concd. NH_4OH . After 20 mins. with frequent stirring, allow the ppt. to settle, filter, wash, dry at 110° and weigh.

W. T. H.

Determination of the platinum metals in ores and concentrates. H. R. ADAM. *J. Chem. Met. Mining Soc. S. Africa* 29, 106-15(1928).—The methods of the Govt. Areas Lab. in the Transvaal are discussed. The sample for analysis should at least pass a 90-mesh sieve. All assay methods require a preliminary fusion and collection of the precious metals in a Pb button. The basic nature of the ores demands a flux rich in SiO_2 and if appreciable Ni and Cu are present the addition of some Pb_3O_4 makes it certain that these elements will be slagged off. The temp. of fusion and cupellation should be a little higher than for Au assay. With a good fusion there is little danger of slag loss. In parting with H_2SO_4 there is loss of Pd if the heating is continued too long, it is best to stop heating as soon as all the Ag dissolves. In the Potgietersrust district, the Pt : Pd ratio is about 1:1 and the parting is difficult so that it has become customary to report "total platinoids" by simply weighing the cupelled bead without inquartation but using a high finishing temp. in a coal-fired muffle. The "prills" thus obtained are analyzed periodically and suitable corrections made. There is a slight slag loss by this procedure. For the analysis of ore concentrates the practice of collecting the precious metals in Ag has been abandoned. The final "prills" from the electric furnace are cleaned in AcOH and weighed. When a sufficient weight has been collected, they are dissolved in *aqua regia* and HNO_3 is removed by evapn. with HCl. The soln. is dild. to 20 cc., allowed to settle, filtered and washed with a little alc. The insol. residue is ignited and cupelled. The small resulting "prill" is heated to 1300° ; it contains Pt metals and Pb but usually weighs very little. The Pt in the filtrate obtained above is pptd. with NH_4Cl , filtered and washed with satd. NH_4Cl soln. It is then dissolved in hot water and Pt pptd. with HCO_2H as recommended by Krauss and Deneke. In the filtrate from the Pt, HCO_2H pptn., dimethylglyoxime pptn. and treatment with nitroso- β -naphthol have all been tried and each method has its advantages.

W. T. H.

Assay for platinoids in ores. JOHN WARSON. *J. Chem. Met. Mining Soc. S. Africa* 29, 115-8(1928).—The flux recommended is $3\text{Na}_2\text{CO}_3$, 3PbO , $1\text{Na}_2\text{B}_4\text{O}_7$ and 1.5AgCl . Detailed directions are given for carrying out the fusion, cupelling, parting with H_2SO_4 , testing with KI and recovering AgCl .

W. T. H.

Colorimetric estimation of thallium. CONRAD STICH. *Leipzig. Pharm. Ztg.* 14, 27-9(1929).—The tests were carried out in the usual 100-cc. glass cylinders, the reagents being added in the following order: (1) sample soln. (test soln.), (2) KOH soln. (about 3 cc.), (3) about 50 cc. H_2O , (4) about 3 cc. Na_2S soln. (5%), (5) H_2O to mark, (6) compare with control.

W. O. E.

Determination of molybdenum in steel in the presence of tungsten and vanadium. J. KASSLER. *Lab. der Poldihütte in Kladno. Z. anal. Chem.* 76, 113-20(1929); cf. C. A. 22, 3860; 23, 1078.—In brief, the method is as follows: Treat 5 g. of steel with 80 cc. of concd. HCl and oxidize with 10 cc. of concd. HNO_3 . Heat for 15 mins. at $80-90^\circ$ in a covered beaker. Remove the cover glass and after another 15 mins., transfer

to a 100-cc. measuring flask, using dil. HCl. Make up to the mark, mix and filter through a dry, double filter. Pour the turbid filtrate through the filter again and use 80 cc. for the further analysis. With steels low in W, the ppt. is free from Mo but in the case of high-speed steels, it will always contain appreciable Mo which must be detd. colorimetrically. Provision is made, therefore, for testing the ppt. for Mo. The nitrates in the filtrate are changed to chlorides by repeated evapn. with HCl and SiO₂ removed in the conventional manner. The soln. is nearly neutralized and treated with 25 cc. of 20% Na₂S₂O₅ soln. which serves to reduce about half of the Fe to the bivalent state. The hot soln. is then poured into 120 cc. of 24% NaOH soln. which causes the pptn. of all Fe and V. The liquid is dild. to exactly 500 cc. and 250 cc. used for the Mo detn. This is accomplished either by pptn. with Pb(OAc)₂ and weighing the Pb-MoO₄ or by reducing with Zn and titrating with KMnO₄. W. T. H.

Note on the determination of vanadium in steel. KARL SWOBODA. *Chem.-Ztg.* 52, 1014-5(1928).—The following convenient method provides for the pptn. of V as vanadomolybdate, with ultimate reduction to vanadyl salt and titration with permanganate. Treat 2 g. of steel in a 500 cc. Erlenmeyer flask with 50 cc. of 6 N H₂SO₄, oxidize the resulting soln. with HNO₃ and add 5 cc. of concd. acid in excess. Boil till no more nitrous fumes are evolved, add 50 cc. of 1% (NH₄)₂S₂O₈ soln. and boil 3-8 mins. which should cause all WO₃ to dissolve. Add 50 cc. more of the persulfate soln. and 100 cc. of (NH₄)₂MoO₄ soln. such as is commonly used in steel analysis. Then add concd. HNO₃ until a clear soln. is obtained, heat to boiling and to the boiling soln. slowly add 10% Na₂HPO₄ soln. at the rate of 4-6 drops per min. until the ppt. changes from dark orange to light yellow in color. This should take 10-40 drops according to the V content. Continue heating, while rotating the contents of the flask, until the ppt. begins to bump. Filter and wash with NH₄HSO₄ soln. (20 cc. of concd. NH₄OH and 25 cc. of concd. H₂SO₄ added to 1 l. of water). Transfer the washed ppt. back to the flask and add in succession, 50 cc. of concd. HNO₃, 5 cc. of H₃PO₄ (d. 1.71) and 50 cc. of H₂SO₄. Evap. to fumes, cool, add 20 cc. of water and 5 drops of concd. HNO₃ (or some concd. KMnO₄), cool and evap. with 50 cc. of 6 N HCl till the soln. fumes strongly. Cool, dil. with 200 cc. of water and titrate at 80°. W. T. H.

Method for the rapid determination of zinc. G. SPACU AND J. DICK. *Univ. Cluj. Bul. soc. stiinte Cluj* 4, 177-80(1928).—The method is based on the pptn. of [ZnPy₂](SCN)₂. The following washing solns. are needed: (1) 3 g. NH₄SCN + 5 cc. pyridine in 1000 cc. H₂O; (2) 13 cc. 95% alc. + 85.5 cc. H₂O + 1.5 cc. pyridine + 0.1 g. NH₄SCN; (3) 10 cc. abs. alc. + 1 cc. pyridine; (4) 15 cc. Et₂O + 2 drops pyridine. The procedure is as follows: add 0.5 to 1 g. NH₄SCN to 50-75 cc. of cold, dil., neutral Zn soln., add 1 cc. pyridine; shake; after 15 mins. filter through a Gooch filter, using soln. (1) to transfer the ppt. to the filter; wash several times with (2); use as little as possible of (3) to wash the walls of the filter and drive off H₂O; wash 6 times with (4); dry with suction, then in a vacuum desiccator and weigh. A neg. error of about 0.5% is to be expected when large quantities of NH₄ salts are present. Weakly acid solns. are treated with NH₄SCN, neutralized with pyridine, then given an extra cc. of pyridine for pptn. Strongly acid solns. are evapd. to dryness, then dissolved in H₂O and treated. The results are, on the whole, very good. ALBERT L. HENNE

The separation of zinc as sulfide from slightly acid solutions. J. MAJDEL. *Univ. Laibach. Z. anal. Chem.* 76, 204-12(1929); cf. *C. A.* 22, 3600.—For the pptn. of ZnS the soln. should not contain more than 0.3 g. of Zn in 300 cc. and not less than 3 g. of (NH₄)₂SO₄ should be present, H₂S should be passed through the soln. for at least 30 mins., the temp. should be 65-70° and after the pptn. the soln. must be allowed to stand half an hr. before filtering. The ppt. can be dried, ignited in H₂ in the presence of S and weighed as ZnS. In an ordinary mineral analysis, the Cu and As groups should be removed by treatment with H₂S in the usual manner, the filtrate freed from H₂S by boiling, made neutral with NH₄OH, treated with 8 cc. 0.5 N H₂SO₄, enough additional (NH₄)₂SO₄ added, diluted to 300 cc. and satd. with H₂S. W. T. H.

The detection and determination of mercury as complex ammonium iodide compound. E. H. VOGELZANG. *Pharm. Weekblad* 66, 65-7(1929).—Hg may be detd. by reversing the Nessler reaction for NH₃. A study was made for the purpose of ascertaining the optimum conditions for applying this reaction. Since the color depends on formation of the HgI₃⁻ ion, the concn. of I must be at least 3 times that of Hg. There is also a max. value for the ratio I:Hg, beyond which the reaction no longer occurs. The reaction is quant. only when the ratio lies between 3 and 16. This limitation is a serious objection to the general utility of the reaction. The soln. must be at least 0.02 N in OH⁻; with higher acidity no coloration occurs. An excess of NH₄Cl is without influence, as is also the order in which the alkali and NH₄Cl are added. By judging

the color after several mins. standing, the delicacy of the reaction reaches 2 mg. per l. Colorimetric detn. can be made more accurate by performing several preliminary tests to find the optimum quantity of reagent to add. As a specific application, *e. g.*, in the examn. of Hg_2Cl_2 , 0.04 mg. Hg may be detected in 20 cc. of filtrate. A. W. DOX

New method for determining iodine (halogen) in organic substances. J. SCHWAB-BOLD. *Chem.-Ztg.* 53, 22-3(1929).—The substance is burned in O_2 and the vapors are passed through K_2CO_3 soln. in which the absorbed halogen can be detd. by the method of Winkler or by that of v. Fellenberg. The combustion tube is 90 cm. long and 20-30 mm. in diam. but is drawn out at the front end into a 3-mm. capillary. The tube also contains a Pt contact substance. Excellent results were obtained in the detn. of I in thyroid gland substance, in urine and in moss. W. T. H

Determination of iodine in organic combination, especially in thyroid gland. WILFRED SMITH. *Chemist and Druggist* 109, 125; *Pharm. J.* 121, 88(1928); *Quart. J. Pharm.* 1, 372-7(1929).—A review of previously published methods is given. Hunter's original method is preferred when the I content is fairly high (about 0.2%) and where ordinary accuracy and speed are required. A modification of Kendall's method is given for smaller quantities of I. Other methods are criticized and discussed. W. O E

Method for the quantitative determination of oxygen in the atmosphere. GILES B. COOKE. *Univ. Md. J. Chem. Education* 6, 105-6(1929).—A simple, satisfactory and accurate method suitable for beginners is explained and illustrated. W. T. H

Determination of the sulfur content of gases, particularly gases from coke ovens. FR. HEINRICH AND F. PETZOLD. *Eisen- u. Stahlwerk Hoesch in Dortmund. Z. anal. Chem.* 76, 120-34(1929).—The gas is passed through 2 wash bottles, contg. altogether 270 cc. of a soln. obtained by mixing 180 cc. of 0.5 N NaOH with 90 cc. of 5% H_2O_2 soln. Eventually the residual NaOH is titrated with 0.5 N H_2SO_4 , methyl orange being used as indicator. The gas is passed for about 2 hrs. at the rate of 200 cc. per min. and the change in vol. is taken into consideration. The method provides for the detn. of all gaseous S compds. except thiophene. W. T. H

Determining calcium chlorate in calcium chloride. VITTORIO SACCHI. *La Chim.* 4, 391-2(1928).—Mix 7.092 g. of Ca hypochlorite in a mortar with H_2O , transfer to a 1000 cc. flask, and dil. to the mark. Det. active Cl in 50 cc. of the turbid soln. by Penot's method using iodo-starch paste as indicator, first by spotting on filter paper and finally in the soln. Place another 50 cc. of the turbid soln. in a flask with 2 g. KI, closing with a stopper having 2 holes, each contg. a dropping funnel. Into one funnel place 25-30 cc. concd. HCl and in the other 25 cc. Add the HCl to the soln., agitate and allow the mixt. to stand 1 hr.; then dil. with 200 cc. water. and add the KI soln. Titrate with 0.1 N $\text{Na}_2\text{S}_2\text{O}_3$ without starch paste. R. SANSONE

A quantitatively correct colorimetric method of determining the phosphoric acid of the type molybdenum-blue. A. YU. LEVITZKII. *Nauchno-Agronomicheskii Zhurnal* (Russian) 4, 783-93(1927).—A modification of the Denigés colorimetric method is suggested. The reagents used are: (A) Sulfo-molybdate soln.: made of equal vols. 10% NH_4 molybdate and concd. H_2SO_4 . (B) Cu-Pb reducing buffer; 0.25 g. Pb, 5 cc. of concd. HCl, and 2 drops of 10% CuSO_4 soln. is heated on a water bath until all of the Pb has gone into soln. and then treated with 2.5 cc. of a 10% CuSO_4 soln. The analysis is made as follows: Place a soln. contg. 0.02-0.2 g. of P_2O_5 in a 100 cc. flask, dil. to 80-90 cc. and add 2.5 cc. of reagent A. Shake, add 0.25 cc. of reagent B, dil. to 100 cc., mix and allow to stand 15 mins. Compare in a colorimeter with known P_2O_5 solns. similarly treated. The results of a series of expts. showing the influence of various compds. on the method and results on soils, plants and fertilizers are given. J. S. J.

Why do thiosulfate solutions change their titer? How are they to be stabilized? D. MIGLIACCI. *Boll. chim. farm.* 68, 11-2(1929).—Review of the studies of Mayr and Kerschbaum (*C. A.* 22, 2123). G. SCHWOCH

Decomposition of silicates by strontium salts in metals. J. KAVINA. *Chem. Listy* 22, 267-70(1928).— SrCl_2 or a mixt. with NH_4Cl is used for fusion with silicates in the detn. of alkali metals in the latter. This fusion mixt. corrodes Pt vessels; Ni crucibles cannot be used. Pptn. of Sr as carbonate from aq. exts. of the fused mass is not as complete in the presence of alkali chlorides as in their absence, 0.1 mg. of Sr being, however, readily precipitable from 3 cc. of a soln. contg. 0.2 g. of alkali chlorides. SrCl_2 used alone does not yield satisfactory results. B. C. A.

New method for determining water in calcium nitrate. R. LUCAS. *Z. angew. Chem.* 41, 1367(1928).—The usual method of oven drying is not satisfactory because the hydrated salt becomes liquid below 100° . A more satisfactory method is to use the Markussön method, heating 20 g. with xylene for 6 hrs. and measuring the vol. of the water that distills off with the hydrocarbon. W. T. H.

Note of the determination of water by distillation with hydrocarbons. W. BOLLER. *Chem.-Ztg.* 53, 70(1929); cf. *C. A.* 22, 4408.—The app. is simplified. It consists of a distg. flask, a condenser and a measuring tube all connected glass to glass. The distillate collects in the measuring tube and the lighter hydrocarbon siphons back into the original flask. To avoid bumping, it is recommended to wrap the substance in a bag of fine bolting cloth and the shape of the bottom of the flask is modified with a protuberance on the inside at the lowest point. W. T. H.

Determination of water and crude fat in substances rich in fat. N. D. PRYANISHNIKOV AND S. M. TELNOV. *Landwirtsch. Timirjasev-Akad. Moscow. Z. anal. Chem.* 76, 161-6(1929).—By heating with benzene, the water can be gradually distd. off and measured and by weighing the residue after the heating, the amt. of dry, fat-free substance is detd. In this way excellent results can be obtained with 5-25 g. of original substance. W. T. H.

Method for quantitative analysis of organic arsenites. EWALD URBSCHAT. *Landwirtschaftliche Hochschule, Berlin. Biochem. Z.* 203, 223-5(1928).—A measured amt. of the soln. to be analyzed is placed in a 25-cc. glass-stoppered flask, depending upon the H_2AsO_3 concn. To this are added 0.5 cc. concd. HCl and 0.4 cc. 50% H_3PO_4 and a few drops of a KI soln. The amt. of H_2AsO_3 present can be easily judged by the rate of formation and the extent of the resulting turbidity. The necessary concn. is 0.002-0.010 mg. per cc. The contents of the flask are dild. to about 20 cc. and the reducing reagent is added. This consists of a mixt. of 30 cc. 50% H_3PO_4 , 15 cc. freshly prepd. 20% tannin soln. and 2 cc. 5 N KI. With the amt. of H_2AsO_3 adjusted within the set limits, 3.2 cc. of this mixt. gives the best results when one works with a 25-cc. vol. The contents are then dild. to the 25-cc. mark. Standard solns. are prepd. in the same manner and the turbidity is compared after 24 hrs. shaking. S. MORGULIS

The colorimetric method for the determination of lactic acid. BRUNO MENDEL. *Biochem. Z.* 202, 390(1928).—Two improvements are suggested in the procedure for the lactic acid detn. which depends upon the conversion of the acid into AcH with hot H_2SO_4 , and the formation of a red color with veratrole. The concn. of H_2SO_4 must be const. inasmuch as the degree of AcH formation depends upon the concn. It is recommended to keep the H_2SO_4 in a glass bottle with a glass stopcock fused in the bottom so that the acid can be drawn off without any possibility of the acid absorbing moisture and changing its concn. as is the case when a H_2SO_4 bottle is opened. The air entering the bottle, should pass 2 wash bottles filled with H_2SO_4 and a $CaCl_2$ tube. The color development, too, depends upon the temp. being greatest at 25°. Higher temps. inhibits the color development. The mixt. should therefore be kept in a waterbath, at 25° for 20 mins. before making colorimeter comparison. By means of these improvements it is claimed that even 0.001 mg. lactic acid can be detd. S. MORGULIS

Detection of methanol by mercuric sulfate solutions (Denigès reagent). HERMANN MATTHIES AND PAUL SCHÜTZ. *Univ. Königs-Berg. Pharm. Ztg.* 74, 44-5(1929).—Contrary to the statement of Stainier and Lauwaet, $HgSO_4$ yields with iso-Pr alc. a white (not yellow) ppt. consisting of a mixt. of a mercurio- and mercu-risulfate-acetone compd., since this alc. is first oxidized to acetone before the formation of the ppt. W. O. E.

A new method for determining glycerol with potassium permanganate. A. RAVENNA. *Zymol. Chim. Col. e Zucch.* 3, 174-6(1928).—Treat 140 cc. 0.5% Ag_2SO_4 soln. with 19 cc. N Na_2CO_3 . After standing, decant off the liquid and wash once by decantation. Boil 10% neutral Pb acetate soln. with excess of litharge for 1 hr. and filter off the warm basic Pb acetate ppt. without cooling. For the detn. take 3-5 g. glycerol in a 250 cc. tared flask, and dil. to the mark with water, after standing some time withdraw 25 cc. into a 100-cc. flask, add the Ag_2CO_3 prepd. as described and after 10 mins. add 5 cc. of the basic Pb acetate. Agitate, bring to the mark with water and use 10 cc. of the filtered soln. To this add a little 10% Na_2SO_4 soln. and test with a little more Pb acetate. If further pptn. takes place, repeat the above treatment with another 25 cc. of the original soln., using this time 6 cc. basic Pb acetate. Finally take 25 cc. of the filtered soln. in a beaker, add an excess of $KMnO_4$ and 50 cc. of 18 N H_2SO_4 . Heat on the steam bath for 2 hrs. If the soln. is decolorized add more $KMnO_4$. Titrate in the still hot liquid the excess of $KMnO_4$ with a 0.1 N oxalic acid soln. R. SANSONE

Use of iron reagents in the detection and differentiation of phenols. ALAN H. WARE. *Chemist and Druggist* 109, 126-7; *Pharm. J.* 121, 88-9(1928); *Quart. J. Pharm.* 1, 377-87(1929); cf. *C. A.* 21, 155, 2635, 4023.—Among the more important features of the paper are: (1) a suggested division of the entire group of phenols into 3 classes (A, B and C) which are easily distinguished in practice by the use of Mitchell's ferrous tartrate reagent with appropriate adjustment of pH, phenols of Class A giving a neg.

result to this test, those of Class *B* a violet or purple color and those of Class *C* a deep-brown coloration. Within classes *B* and *C*, individuals may be distinguished by employing an improved pptn. test described for the 1st time. This test is so devised that the Fe complexes produced by individual phenols are pptd. at successive stages in such a way as to give specific results. (2) Expts. are described which show that the textbook accounts of the color reactions given by FeCl_3 with many phenols are inadequate and incorrect. Phenols of Class *B* will give a series of no less than 5 distinct and definite colors with variations of p_H , while those of Class *C*, give only 2 such colors at most. (3) Tests are described in which H_2O_2 is used with FeSO_4 or FeCl_3 in such a way as to give specific distinctive results.

The determination of sugar from the oxygen content of cupric oxide. MICHAEL DIMITROFF HADJIEFF. Agr. Inst. Univ. Sofia. *Z. Untersuch. Lebensm.* **55**, 613-4 (1928).—The Meissl-Allihn detn. for sugars is used. Into a hot mixt. of 60 cc. of H_2O and 30 cc. of Fehling's soln., 25 cc. of sugar soln. is pipetted. The concn. of the sugar soln. must be kept below 1%. After 2 mins., 100 cc. of cold boiled H_2O are added. The Cu_2O is filtered and washed on an asbestos pad in a Gooch crucible and dried at 120-130°. It is then further dried in a current of dry air. The CuO produced is weighed, heated in a stream of dry H and reduced to Cu which is likewise weighed. The difference in wts. gives the O content of the CuO from which the factor 3.9731 may be used to obtain the Cu no., and therefore the sugar content of the sample from the Meissl-Allihn tables.

EDGAR T. WHERRY AND J. F. SCHAIRER

Occurrence of sylvanite (Cu_3VS_4) in the Sierra de Cordoba, Argentine. GEORGE FREBOLD. *Centr. Mineral. Geol.* **1928A**, 27-8.—H. Wiedemann reported sylvanite from this locality, but F. has failed to find it in the same specimens, and believes the mineral described to be galena. No primary V mineral is present.

J. E. G.

Spinels of tervalent cobalt: cobaltous and zinc cobaltite. G. NATTA AND M. STRADA. *Atti accad. Lincei* **7**, 1024-30(1928).—Spinels having the general compn. $\text{Me}^{++}(\text{O})\text{Me}_2^{+++}\text{O}_4$ are known for many bivalent metals: Mg, Zn, Fe^{++} , Ni, Mn, Cd, as well as for the tervalent Al, Cr and Fe. However, all the theoretically possible compns of the general formula do not exist, but only those which crystallize in the cubic system, and whose superior at. diam. is less than 2.10 Å. U. Metals which have both Me^{++} and Me^{+++} forms, as Fe_3O_4 as well as Co_3O_4 , form spinels. The new compd. $\text{ZnO}(\text{Co}_2\text{O}_3)$ was prep'd. by evapg. a soln. containing 2 mols. of $\text{Co}(\text{NO}_3)_2$ to 1 $\text{Zn}(\text{NO}_3)_2$ and calcining the residue at 800°. This product is isomorphous with $\text{CoO}(\text{Co}_2\text{O}_3)$, both crystg. in the cubic system; the dimensions of the space lattices are identical: 8.06 Å. U. \pm 0.005; their sp. gr. = 6.11 and 6.27, resp.

A. W. CONTIERI

The structure and constitution of feldspars. FELIX MACHATSKHI. *Centr. Mineral. Geol.* **1928A**, 97-104.—Silicates so far investigated show O^{-2} ions arranged at

the corners of tetrahedra with Si^{+4} ions as nuclei. This unit is regarded as the basis of silicate structure. The different varieties of silica have each O^{-2} ion shared between two tetrahedra. M. believes that feldspars have a similar structure. Al^{+3} with O^{-2} may have a coordination no. 4 or 6; if 4, Al^{+3} ions may take the place of Si^{+4} ions as nuclei of tetrahedra, which are thereby somewhat deformed. $\text{Be}^{+2} + \text{B}^{+3}$ may be substituted for Si^{+4} in some cases. Tetrahedra cannot be packed to fill space completely. Interstices are filled mostly by K^{+1} , Na^{+1} , Ca^{+2} and Ba^{+2} . M. expresses these relations by the following formulas: K feldspar $\left[\begin{smallmatrix} (\text{SiO}_2)_2 \\ \text{AlO}_2 \end{smallmatrix} \right]^{-1} \text{K}^{+1}$; Ca feldspar $\left[\begin{smallmatrix} (\text{SiO}_2)_2 \\ (\text{AlO}_2)_2 \end{smallmatrix} \right]^{-2} \text{Ca}^{+2}$. Because of the similarity in structure it is considered possible for mixed crystals of quartz and feldspar to form. In the "meta type" of silicate structure tetrahedra are arranged so that the only two O^{-2} ions from each are shared by neighboring tetrahedra. In the "ortho type," O^{-2} ions are not shared by neighboring tetrahedra. Meta type

R''_2 (or $\text{R}'\text{R}'''$). True mols. exist only in the latter structure. J. E. GILL

Comparative x-ray investigation of lime-soda silicates. B. GOSSNER AND F. MUSSING. *Centr. Mineral. Geol.* 1928A, 129-38, 167-81.—X-ray data on, and comparisons of, melilite, gehlenites, arcolite and scapolite are given. J. E. GILL

The structure of crystals of heulandite. PAUL GAUBERT. *Compt. rend.* 187, 829-31(1928).—The compn. of the sections or bands in heulandite which have slightly different μ s. is sufficiently different that HF attacks them at unlike rates. Probably the pure heulandite consists of a solid soln. of the hydrated aluminosilicates of Na, K, Sr and Ba in the Ca salt. The bands are due to the presence of foreign material which causes different rotations of the plane of the optical axes. R. J. HAVIGHURST

The effect of heat and of loss of water on the optical properties of heulandite. PAUL GAUBERT. *Compt. rend.* 187, 1057-9(1928).—Microscopic observations have been carried out on the cleavage plane of crystals set upon heated Pt which had an arrangement for rapid heating and cooling. Heat alone increases the birefringence; the plane of the axes turns and the rotation is augmented. The original values are not obtained when the heat is withdrawn. The phenomenon is rarely reversible owing to the modification of optical anomalies whose effect is superimposed upon the optical properties of the substance. The amt. of H_2O present has considerable effect upon the optical properties. S. L. B. ETHERTON

The structural forms of meteoric irons. RUDOLF VOGEL. *Arch. Eisenhüttenw.* 1, 605-11(1928); cf. *C. A.* 22, 4420.—The results of investigations (*C. A.* 19, 2000) on the Widmannstätten structure, the nature of kamacite and taenite, and the conditions of formation of schreibersite and rhodite in meteoric Fe are given. Mixed crystals of kamacite (6% Ni) and taenite (30% Ni) are formed by the δ - γ conversion, this also causing the Wn. structure. Although at this conversion equil. has not been established the characteristic structure of kamacite and taenite is present. The "conversion figures" are caused by the sepn. from the melt of kamacite, which is surrounded by taenite at 1450° . "Shredded" kamacite is given by the twinning formed in the α - γ conversion. By heating schreibersite and rhodite to 1000° (or over) kamacite is formed, which on cooling does not reform the first 2. The structure and compn. of meteoric Fe is duplicated artificially with the aid of the Ni-Fe and Ni-Fe-P diagrams. J. BALOZIAN

Sampling and coring in prospecting for oil and gas. W. F. CLOUD. *Proc. Oklahoma Acad. Sci., Univ. of Oklahoma Bull.* 1928, New Series 410, Studies Series 30, 128-34.—Samples of underground formations are secured: (1) by using the diamond drill; (2) by collecting bit cuttings from a cable tool or rotary driven well; or (3) by the use of various coring devices, or core barrels which are available for either cable-tool or rotary drilling. Correct examn. of these samples involves not only the identification of the fluid content of the strata but also the detn. of the lithological properties such as % of pore space, % of satn. and permeability. These points are discussed in detail. W. T. H.

Sampling and coring in prospecting for metalliferous deposits. H. C. GEORGE. *Proc. Oklahoma Acad. Sci., Univ. of Oklahoma Bull.* 1928, New Series 410, Studies Series 30, 137-40.—The examn. of churn drillings and of diamond drillings are discussed from the standpoint of the mining engineer. W. T. H.

Eastern Canada in 1928. ANON. *Mining J.* Annual Review No. 1929, 21; **British Columbia in 1928.** *Ibid* 23; **Western Australia in 1928.** *Ibid* 23; **New Zealand in 1928.** *Ibid* 24; **Nigeria in 1928.** *Ibid* 26-7; **Cornwall and Devon in 1928.** *Ibid* 27-8; **Mining in Portugal in 1928.** *Ibid* 29; **Ceylon in 1928.** *Ibid* 29.—Brief reviews of the mineral production in various countries for 1928. ALDEN H. EMERY

Mineral wealth of Zambesia. ANON. *Mining J.* Annual Review No. 1929, 25. — There is a wide distribution of Cu in S. Africa. The main known ore bodies are in Katanga and N. Rhodesia. These have numerous outliers. Immense beds of coal have been proved. Rich and extensive bodies of magnetite await exploitation near the Tete coal field. Pb, Zn, Au and Ag are known to occur. ALDEN H. EMERY

Southern Rhodesia. A review of its mineral resources. ANON. *Mining J.* Annual Review No. 1929, 64.—By the end of 1928 Rhodesia had produced about \$500,000,000 of minerals, of which Au was the most important (more than 70%). Quantities of Cu, Cr, Ag and asbestos have also been recovered. Base metals have recently grown greatly in importance. In 1909 they were produced in the ratio of 1:17 to the Au industry; in 1927, 1:1.6. Asbestos is now the second most important mineral product and the country is the leading producer of high-grade material. Cr ore is next. Coal is becoming of increasing importance. ALDEN H. EMERY

Hydrothermal formation of iron ores. R. KLEMM. *Centr. Mineral. Geol.* 1928A, 90-4.—K. failed to obtain anhydrous Fe oxides corresponding to magnetite and hematite by reaction of solns. of Fe chlorides and sulfates with carbonates and silicates at temps. of about 100°. The conditions were identical with those described by Kuhara (*Japanese J. Geol.* 4, 1-32(1925)), who reported such oxide ppts. J. F. GILL

Martitization of magnetite formations. RENÉ VAN AUBEL. *Pub. Rel. Congo Belge, (Ann. soc. geol. Belgique)* 51, c5-8(1928).—Martite occurs as a narrow corona around grains of magnetite. On the faces it forms a triangular network following the trace of the faces of the octahedron. Martite is later than magnetite. The mass in which it occurs is near a diorite-diorite intrusion, and it probably formed as the result of magmatic emanations. O. F. POINDEXTE

Platinum and platiniferous deposits. L. DUPARC. *Rev. univ. mines* 57, 18, 157-66(1928).—Pt occurs mostly in dunite but also in pyroxenite, the chem. compn. of the 2 being somewhat different. D. suggests a theory as to its origin. H. S. W.

The platiniferous deposits of the Birbir (Abyssinia). L. DUPARC AND E. MOLLY. *Bull. suisse min. pet.* 8, 240-57(1928).—Pt occurs in dunite; an analysis of it is given. Chemically the Abyssinian Pt resembles that of the Urals. H. S. WASHINGTON

Cyanite as found in Western North Carolina. A. H. FESSLER AND WM. J. McCaughy. *J. Am. Ceram. Soc.* 12, 32-6(1929).—The deposits are described. The mineral promises to be important in certain phases of the ceramic industry. C. H. K.

A phosphorite conglomerate at Gotland. HERMAN HEDSTRÖM. *Geol. Fören. Förh.* 50, 429-35(1928).—Pebbles in the conglomerate consist of phosphorite and phosphorite-sandstone with round particles of pure quartz 1-2 mm. long. Analysis of the rock as a whole shows: CaCO_3 86.17 and P_2O_5 0.41%, corresponding to 0.90% of $\text{Ca}_3(\text{PO}_4)_2$. The phosphorite pebbles are homogeneous and of a dull gray color, the largest being 2×1 cm. Analysis gave 35.26% P_2O_5 , corresponding to 77.00% of $\text{Ca}_3(\text{PO}_4)_2$. The phosphorite-sandstone pebbles vary in color from brownish yellow to dark brown. They are well rounded. The size varies from a few mm. to nearly 10 cm. A typical one measured $7.5 \times 6 \times 3$ cm. The binding material is rounded grains of quartz. Analysis gave P_2O_5 11.68%, corresponding to 25.51% $\text{Ca}_3(\text{PO}_4)_2$. H. compares the Gotland conglomerate with one found in the Silurian in the nearby Höggrän-Vall region, with special reference to the analysis, to variations in the phosphorite-sandstone, and to the fossils present. W. SEGERBLÖM

Asphalt and some other minerals found in the Silurian strata at Gotland. HERMAN HEDSTRÖM. *Geol. Fören. Förh.* 50, 443-8(1928); cf. preceding abstract.—The asphalt is black, lustrous and coal-like in appearance. Analysis gave 1.9% brownish ash, which after decompn. showed traces of Cr or V; the asphalt melted when heated with blast and gave a large amt. of combustible gas. Later examn. showed that it was radioactive. Other minerals found in the Silurian include: calcite as pyramidal crystals, chalcopryrite, sphalerite, galena, pyrite, marcasite, barite, aragonite, flint, glauconite and a yellowish red to blackish brown Fe oxide. W. SEGERBLÖM

Asphaltite from the Philippine Islands. E. T. HODGE. *Philippine J. Sci.* 37, 263-72(1928).—The properties of grahamite, asphaltite from the Philippines, manjak and uintahite are given; the asphalt is considered to lie between manjak and grahamite. The high % carbon indicates metamorphosis by heat and thus it resembles Oregon asphalt and is dissimilar to many occurrences in other parts of the world. The high

ash may be explained by long surface exposure in a tropical country expedited by the heat of adjacent intrusions, the asphaltenes being oxidized. Grahamite occurs in W. Virginia, Oklahoma, Utah, Colorado, Oregon, Cuba, Mexico, Trinidad and Barbadoes. It is chiefly used in the roofing industry and for varnishes. Trinidad manjak has a higher sp. gr. than the Barbadoes material, the latter being more valuable economically. It is used in paints, varnishes and pipe cements. S. L. B. ETHERTON

Mining geology. J. VOLNEY LEWIS AND JOSEPH M. WANENMACHER. *Eng. Mining J.* 127, 112(1929); cf. *C. A.* 22, 748. E. C. M.

Change in density of minerals and rocks on heating. SHUKUSUKE KOZU AND JUNICHI UEDA. *Tohoku Imp. Univ. J. Geol.* 35, 399-406(1928).—When granite is heated, it expands abruptly at 575° and breaks, so that a special method is necessary to know the expansion coeff. at high temp. K. and U. determined the expansion coeff. of quartz, feldspar and amphibole from ordinary temps. up to 1000° and deduced the formula for calcg. the expansion of granite. Thus, for granite contg. 30% quartz, 65% feldspar and 5% amphibole, there is a vol. increase of 1.85% at 500° and 3.72% at 1000°. The decrease of d. as calcd. from the vol. change is 3.82%. This vol. change of granite is geologically important because it must affect the earth's crust near bodies of this rock very considerably. K. SOMEYA

Some dike-rocks in Japan. TSUTOMU OGURA. *Mem. Ryojun Coll. Eng.* 1, 137-44 (1928).—The dike-rocks in the Tatara-yama region may be divided into quartz veins, pegmatites (feldspar and quartz), aplites (orthoclase, oligoclase and quartz, with a little biotite) and porphyrites, of which 3 types are distinguished: pyroxene-hornblende-porphyrity, two-pyroxene-porphyrity and two-pyroxene-hornblende-porphyrity. Analyses are given of granite, aplite and two-pyroxene-porphyrity. C. J. WEST

Structural differences of the primary and secondary lava flows of Dafni volcano. N. LIATSIKAS AND G. GEORGALAS. *Centr. Mineral. Geol.* 1928B, 337-42.—Differences in texture serve to distinguish the lavas. Their mineral and chem. compns. are almost identical. J. E. GILL

The lava of Etna. W. F. GISOLF. *Proc. Acad. Sci. Amsterdam* 31, 660-9(1928).—*See C. A.* 22, 3868. E. H.

Alkaline rocks of the volcano Merapi (Java) and the origin of these rocks. H. A. BROWER. *Proc. Acad. Sci. Amsterdam* 31, 492-8(1928).—*See C. A.* 22, 2127. E. H.

Conglomerate in the Cambrian sandstone in Djupadal, Västergötland, Sweden. IVAN D. WALLERIUS. *Geol. Foren. Forh.* 50, 799-800(1928).—The pebbles of the conglomerate consist of fine, hard, brownish sandstone with streaks of pyrite, imbedded in a coarse-grained sandstone rich in pyrite. Analysis of the pebbles showed only a trace of P_2O_5 . Fossils and Ca are absent. W. SEGERBLOM

Fossilized sulfur bacteria in aluminum schists at Kinnekulle. SVEN V. BERGH. *Geol. Foren. Forh.* 50, 413-8(1928).—Preliminary notice of fossilized S bacteria occurring in the Al schists gathered from Gössäter, Kinnekulle and placed in the Technical High School Metallographic Institution. The schists are made up of a clay-like, sedimentary, bituminous rock composed of mica, quartz, feldspars, calcite and pyrite. Five photomicrographs, at 250-2000 magnifications, show the bacteria. W. SEGERBLOM

Investigation of the magnetic properties of rocks. A. TOURTSEV. *Bull. Acad. Sci. U. R. S. S.* 1928, 89(1928).—T. shows how hysteresis loops and curves of magnetic permeability of certain rocks and minerals may be obtained, and their mineralogic compn. detd. with a view of ascertaining which components influence these magnetic properties. C. G. F.

The action of carbonated waters on rocks. P. G. LIEGEOIS. *Ann. soc. geol. Belg.* 51, B232-6(1928).—Acid and basic eruptives, metamorphic rocks and vein minerals were immersed for periods from 6 months to a year for the purpose of observing the action of mineral waters on some of the principal materials of construction. Quartzite and compact granite, syenite, diabase, etc., show, no alteration when subjected to a microscopic examn. and compared to the fresh rock. Less compact rocks show alteration of black mica, pyrite and other Fe-bearing minerals. In one granite the feldspar was altered. O. F. POINDEXTER

Action of sulfur dioxide on glasses and basic rocks at high temperature and the probable origin of thermal sulfated waters. ALBERT PORTEVIN. *Compt. rend.* 187, 1148-50(1928).—At a high temp. even a small amt. of SO_2 in a gas superficially and selectively attacks glasses and basic rocks and almost always produces Na_2SO_4 exclusively, in spite of the low Na content. At the surface of some samples coming from the annealing furnace the attack shows as a transparent enamel. The formation of sol. sulfates thus indicated together with the presence of steam and hot water will ac-

count for the existence of thermal waters with a high mineral content and containing alkaline sulfates. S. L. B. ETHERTON

Catalog of Swedish geological, paleontological, petrographic and mineralogical literature for 1927. R. SANDEGREN. *Geol. Fören. Förh.* 50, 788-98(1928).—Continuation with 197 titles of the list described in *C. A.* 21, 881. W. SEGERBLOM

Annual review of Swedish literature concerning Post-Tertiary geology. *Geol. Soc. STOCKHOLM. Geol. Fören. Förh.* 50, 751-87(1928).—The first of a series of résumés of Swedish books and lengthy articles, covering 1927. It is planned to publish this review in English, French and German. This covers 55 titles, on various phases of geology, biogeology, soils, etc. W. SEGERBLOM

Reply to Mr. N. D. Zelinskii (cholesterol as the mother substance of petroleum). WILHELM STEINKOPF. *Ber.* 61B, 1639(1928); cf. *Z.*, *C. A.* 22, 4418. C. A. R.

D. J. DEMOREST, R. H. ABORN

Hydrometallurgy. G. D. VAN ARSDALE. *Eng. Mining J.* 127, 109 (1929)

Pyrometallurgy—copper and lead. E. H. ROBBIE. *Eng. Mining J.* 127, 115 (1929). Zinc. W. R. INGALLS. *Ibid* 115; cf. *C. A.* 22, 748. E. C. M.

Ore dressing. CHARLES E. LOCKE. *Eng. Mining J.* 127, 107(1929); cf. *C. A.* 22, 748. E. C. M.

Ore dressing of molybdenum ore. GAICHI YAMADA. *Monthly J. Mining and Met.* 6, 205-22(1928); cf. *C. A.* 23, 1086.—The raw molybdenite ore contains about 1% of MoS_2 , but the product required in the market as refined ore is of about 85% grade, so that the ore dressing is very important with molybdenite. To meet this demand and also for greater efficiency, froth flotation is exclusively preferred. Molybdenite can be readily treated by flotation and is well fitted for dressing, but the raw ore is accompanied in many cases by pyrite, which considerably lowers the quality of the product of flotation. The dressing method is the same as methods generally applied; i. e., large grains are dressed by hand, while the finer, scaly ones are crushed. To obtain a high-grade ore, a comparatively large grain is necessary, but when too large, there is a danger of its escaping flotation and going away into the tailing; so the grains are usually ground to below 35-mesh fineness. Pine oil is used for frothing, and kerosene for collecting; the quantities vary according to the nature of the ore and the degree of grinding. The usual quantities are: pine oil, 0.25 lb./ton, kerosene, 0.5-0.7 lb./ton. According to Y.'s expt. a mixt. contg. 8 parts of camphor oil and 2 parts of coal tar gave a much better result. Too much oil lowers the quality of the refined ore. Such reagents as lime or soda improve the quality of the refined ore, but make use of a larger quantity of oil necessary. When pyrite or other sol. salts are present, better results are obtained by using alk. reagent. Some of the pyrite found in the refined ore can be removed by sieving. K. SOMEYA

Treatment of complex ores in the southwest. H. B. MENARDI. *Mining J. (Arizona)* 12, 7(1929).—Selective flotation has made possible the profitable handling of many complex ores. E. M. SYMMES

Methods of preparing and cleaning some common heavy liquids used in ore testing. R. G. O'MEARA AND J. BRUCE CLEMMER. *Bur. Mines, Repts. of Investigations* No. 2897, 6 pp.(1928).—To prep. $\text{C}_2\text{H}_5\text{Br}$, place 1000 g. liquid Br in 3 or 4 gas-washing bottles, add a small quantity of water to prevent excessive volatilization of Br. Bubble C_2H_5 gas slowly through the wash bottles until a change in temp. or a light amber color shows the reaction to be complete. Provide a simple cooling device to prevent excessive temp. rise and to increase the rate at which C_2H_5 may be passed into the brominating

chamber. Place the resulting heavy soln. into a separatory funnel and agitate with a dil. caustic soln. to remove the uncombined Br. Allow to stand until a definite sepn. of water and the $C_2H_5Br_4$ takes place. Draw off and dehydrate with $CaCl_2$. A yield of 90 to 96% is obtained. To reclaim from sink-and-float samples wash several times with C_2H_6 or CCl_4 . Remove diluents if desired by evapn. and filter. Avoid overheating as discolored $C_2H_5Br_4$ is of little value and must be cleaned by successive treatments with Br, NaOH and $CaCl_2$. To prep. CH_3I treat a kg. of CHI_3 in a 5 l. round-bottom flask with 500 cc. of Na_2HAsO_3 soln. made by dissolving 274 g. As_2O_3 and 532 g. NaOH in 2600 g. water. Stir with a mech. stirrer, bringing the temp. to 60° to 65° and hold const. during the reaction. Add the remainder of the arsenite soln. gradually during 0.5 hr. In 1 hr. after the last addn. the reaction is complete. Cool to 40° and filter. Draw off the CH_3I , which is the pale yellow oil in the lower layer and dehydrate with $CaCl_2$. If desired to purify distil in vacuum at 7 cm. pressure and 106° . CH_3I may be reclaimed from sink-and-float samples in essentially the same way as $C_2H_5Br_4$, except that heat must not be applied in evapn. to remove C_2H_6 and CCl_4 . If red in color agitate with a dil. soln. of NaOH or KOH, Na_2CO_3 , $Na_2S_2O_3$ or Na_2HAsO_3 . Draw off the lower CH_3I layer and dehydrate with $CaCl_2$. To prep. thallium formate roll Tl metal into a thin sheet and wash with a grease solvent. Add formic acid. Allow to react to completion on a sand bath. Pour off the soln. and add new acid. Repeat until Tl is dissolved. Evap. the liquid to dryness, redissolve in distd. water, again evap., then make into soln. of the desired sp. gr. To recover, wash the products with hot distd. water. Filter through a fast filter, place on a sand or water bath and allow to evap. to the desired sp. gr. or to solid salt. Tl malonate-formate is a mixt. of 1 mol. wt. of the malonate and the formate. Prep. Tl malonate by dissolving Tl in H_2SO_4 . Treat the sulfate with $Ba(OH)_2$. Filter off $BaSO_4$ and add malonic acid to neutralize the filtrate. Evap. the Tl malonate to dryness. Mix a mol. wt. of the malonate and the formate in soln. and evap. to dryness. Recover from sink and float samples in a manner similar to that employed for formate. Filter the salt soln. to remove the residue formed during evapn. Treat the residue with formic acid to produce new Tl formate to be placed in formate washings. Evap. the Tl malonate-formate on the sand or water bath to the desired sp. gr. or to solid salt. $C_2H_5Br_4$ has a sp. gr. of 2.95, CH_3I 3.3, Tl formate 3.5 and Tl malonate formate 3.5 to 4.9.

H. C. PARISH

Concentration of Britannia ores. H. A. PEARSE. *Trans. Can. Inst. Mining and Met.* 30, 915-28(1927).—The ore consists of a mixt. of chalcopryrite and iron pyrites in a hard quartz-porphry gang. The constituents being relatively coarse are readily freed from one another by grinding to 60-mesh. During the coarse-grinding stages in gyratory crushers and rolls the slime and fine ore are periodically washed out through screens in order to remove sol. salts which interfere with the subsequent flotation. The final grinding is effected in wet ball-mills using a pulp contg. 6.5% of solids, and the discharge after addn. of a small quantity of lime passes directly to the rougher cells in which the sulfide minerals and the Au and Ag are sepd. from the gang. The flotation agents used are 0.05 lb./ton of K xanthate, added partly at the head and partly in the middle of every rougher, and 0.15 lb./ton of a mixt. of 80% of coal tar and 20% of Canadian hardwood creosote added at the grinding mills. To produce a stable froth 0.25 lb./ton of steam-distd. pine oil is added with the xanthate, and sometimes small quantities of Na resinate are added at various points along the roughers. The primary slimes obtained in the early stages of crushing are washed, treated with 8 lb./ton of Na_2CO_3 , and floated with 0.3 lb./ton of xanthate, 0.15 lb./ton of pine oil, and 0.05 lb./ton of fumol (a condensation product of AcH). The av. concentrate from the rougher cells contains 9-15% Cu; it is classified and the underflow is reground with 1.5-2 lb./ton of slaked lime. The overflow from the classifiers and the discharge from the regrinding mill are refloats with the addn. of a little pine oil; the concentrates from this operation average 20% Cu, the pyrite having been deadened by the addn. of lime, and the tailings 3% Cu. The latter are retreated in a Forrester pneumatic machine to obtain a middling product with 12% Cu which is re-treated with further quantities of rougher concentrates. The tailings from the Forrester machine are passed over blanket tables to recover free Au, then passed to other Forrester machines in which the pyrite is floated with 0.3 lb./ton of xanthate. The recovery of pyrite is 60% of that in the mill feed, and the product assays 49.8% S, 44% Fe, 0.35% Cu, and 4.5% of insol. material; the recovery of Cu in the first concentrates is 91.3% and the recovery of Au on the blankets about 62%. The cost of treatment of the ore is 42.6 cents/ton, of which 4.5 cents is the cost of flotation reagents and 16.1 cents the labor cost.

B. C. A.

Determination of flakiness of ores. WILL H. COGILL, O. W. HOLMES AND A. B. CAMPBELL. *Bur. Mines, Repts. of Investigations* No. 2899, 7 pp.(1928).—Flakiness

of ores is detd. by sizing on square holes and then screening on oblong holes. In every instance the cubical grains had a higher Zn content than the flaky grains in Tri State jig tailings. E. g., in the 4- to 5-mesh product the cubical grains assayed 1.87% Zn and the flaky grains 1.08%. The same degree of flakiness was shown by Tri State chert and Southeast Missouri Pb belt dolomite when similarly ground. The discharge from rolls was more flaky than that from the ball mill. Some evidence was obtained to show that the size of max. flakiness in the discharge is a certain fraction of the size of the feed.

H. C. PARISH

Preliminary examination of low-grade bauxite with particular reference to flotation. B. W. GANDRUD AND F. D. DE VANEY. *Bur. Mines, Repts. of Investigations* No. 2906, 8 pp. (1928).—The phys. characteristics of low-grade bauxite have been studied, special attention being given to the possibility of applying com. methods of concn. to low-grade bauxite. Silica and Fe are the most objectionable impurities requiring removal in the ores of the Alabama-Georgia-Tennessee-Mississippi district. Na_2S and oleic acid successfully floated gibbsite from kaolinite and free silica. The bauxite required conditioning with the Na_2S before adding the oleic acid. Violent stirring and agitation for 10 min. before the addn. of the oleic acid give sufficient conditioning. The addn. of kerosene or machine oil with the oleic acid facilitated the flotation. Results of flotation tests with 50-g. and with 500-g. machines are tabulated. Sepn. of mineral and gang was very inefficient until the minus-275-mesh material had been removed by screening. The Na_2S cost is about 18¢ per ton (909 kg.) of ore treated. Flotation concentrates, as a rule, showed a higher Fe content than the original ore. The flotation of high-silica bauxite should have possibilities of com. application as a process for obtaining pulverized bauxite of chem. grade from low-grade ores. W. H. BOYNTON

Economy in roasting spathic iron ore. LUDWIG A. RICHTER. *Arch. Eisenhüttenw.* 1, 725-7 (1928).—As contrasted with the roasting methods used at San Fernando and Apold-Fleissner the roasting costs in the old roasting furnaces are high. The most economical is the roasting process of Apold-Fleissner.

J. BALOZIAN

The cyanide process applied to an insoluble manganese-silver ore. HEIKICH SARTO. *Taiu Mining Works. Japan J. Mining* 44, 753-84 (1928).—When the Ag ore accompanies Mn oxide, part of the Ag is difficultly sol. in the cyanide soln. and there is as yet no established theory as to the nature of the insol. portion. S. studied the application of the direct cyanide process, sulfurous acid process and the reduction process to this kind of ore, to find a simple and economic method of operation. *Results.* In the direct cyanide process there is found to be a limit in the amt. of insol. Ag formed, the grain size, time and the concn. of the soln. exerting little influence. T. supposes that the insol. Ag has originally been sol. but has changed into an insol. form, after or simultaneously with its oxidation. When the insol. Mn-Ag ore is treated by H_2SO_4 to remove Mn oxide, the insol. Ag can be made largely sol. The velocity of soln. of Mn oxide in H_2SO_4 is very great but is affected by impurities sol. in the acid so that the dil. acid is most advantageous. *Conclusion:* A good result is obtained by applying the cyanide process after removing Mn oxide. S. next tested the reduction process and concludes: This kind of ore may be made sol. by adjusting the temp. of reduction and the kinds of the gas used. The temp. of C deposition, etc., depends upon the kind of ore used, it being generally important to work at about 350° where the C deposition is small or at a much higher temp. of 700°. In applying the cyanide process to the reduced ore it is important to add a sufficient quantity of protecting lime and cause air oxidation by stirring to take place in order to lessen the danger of making the KCN consumption large. S. states that the insol. Ag ore is probably present as a kind of hard Mn ore of the compn. $x\text{Ag}_2 \cdot y\text{MnO}_2$.

K. SOMEYA

Speiss and the metals of the platinum group. H. RUSDEN AND J. HENDERSON. *J. Chem. Met. and Mining Soc. S. Africa* 29, 66-7 (1928).—Fusion speiss is difficult to roast but a finely crushed sample mixed with damp sand (1:1) should be workable in a good roasting furnace with recovery of As. Fusion of the roasted product mixed with mealie meal in a crucible with assay slag as cover is fused 1 hr. at a high temp. and poured into a mold. The resultant bead consists of Ni and Cu with some platinumoids. The detached slag is returned to the crucible and given a couple of washes to recover the remaining precious metals in the Pb. This means of collection of the bulk of the Ni and Cu renders their recovery by the usual methods possible. No data are given.

W. H. BOYNTON

Problems of the platinum market. ALBERT LINDE. *Edelmetalle-Vertriebs A.-G., Berlin. Mining J. Annual Review* No. 1929, 10.—L. predicts an increased demand for Pt in 1929.

ALDEN H. EMERY

Solving a fume problem. W. H. ROWLEY. *Eng. Mining J.* 127, 232-3.—A de-

scription of the dust recovery system in the lead oxide plant of the Evans-Wallower Lead Co. at Charleston, W. Va. An automatic self-cleaning filter machine has been efficient and economical, eliminating a great deal of waste, labor turn over, sickness and other difficulties. The complete equipment consists of filters, air suction lines, hoods, and accessory equipment in connection with the mills, screens, mech. conveyors, elevators, and packers about the plant.

Can pulp thickening be simplified? E. G. HOWE. *Eng. Mining J.* 127, 157-9 (1929).—Area is a dominant factor in pulp thickening varying with: class of material, d of feed, flocculating agents used, temp., etc. Recent machine developments combine the principle of compression with filtration all more or less intermittent in character. Examples of the use of cones for slime thickening are outlined, also the possibilities of using conical tanks. Everything points to the adaptability of the baffled spitzkasten of large area to the thickening of flotation pulps, with debatable possibilities on cyanide slime and the need for a dense product. The application of such a tank to the thickening of flotation concentrate would be worthy of consideration. W. H. BOYNTON

Tin mining in Malaya. ANON. *Mining J. Annual Review No. 1929*, 33.—Malaya produces about 35% of the world's Sn output by 4 methods: open-cast mining, gravel pumping, hydraulicking, and bucket dredging. Each is described. A. H. E.

Oxygen in cadmium copper. CLEMENT BLAZEY. *Metal Ind.* (London) 34, 3-4 (1929).—Deoxidation by Cd, while resulting in some loss of Cd, may be controlled in a manner that affords satisfactory results. Expts. show that, with sufficient time, practically all Cd may be removed from a bar, rod, or wire in an oxidizing atm. The properties of wires drawn from rods subjected to prolonged heating in air are tabulated. After 336 hrs. nearly all of the Cd has been driven out of the rod. Analyses of the central and outer portions of the original rod showed that the Cd was uniformly distributed and that the loss of strength and gain of cond. of the wires were not due to removal by oxidation of a high-Cd outer portion of the rod. W. H. BOYNTON

The importance of recovered or "secondary" tin. J. B. RICHARDSON. *Bull. Inst. Mining Met.* No. 291, 32 pp.(1928).—The world is threatened with a Sn shortage because the known Sn fields are being worked out and no new fields are being discovered. A great increase in "secondary" Sn could be accomplished by adopting the following suggestions: (1) Municipal and other authorities should improve and cheapen the methods of collecting Sn-bearing refuse. (2) Industries consuming Sn in any form should give more attention to the classification and retention of Sn-bearing by-products in their most concd. form. At all costs diln. should be avoided. (3) Metal merchants and collectors should use better grading methods. Smelters could assist by putting a greater premium on clean material and more heavily penalizing heavily deleterious matter in all Sn-bearing material. (4) It could be desirable to have the treatment of Sn-bearing metals and residues in the hands of fewer but larger firms possessing ample resources and the technical skill to install new or to improve old plant and to take up new proved processes. Now hundreds of small firms are treating, some wastefully. (5) More assistance should be received from metallurgists in the development or invention of processes for the isolation of Sn; for the disocn. of one or more metals from the alloys of Sn and their residues; and for a greater degree of concn. of Sn in the present processes so that the recovered Sn may become more flexible in its re-applications. (6) Disseminate the accumulated technical work and knowledge on this subject more freely. (7) Collect and publish by appropriate government authority, statistics on production of "secondary" or recovered Sn. H. C. PARISH

Wrought iron made by a new process. CHARLES LONGENECKER. *Blast Furnace & Steel Plant* 17, 263-5(1920).—A new process of making wrought Fe is carried out by melting Bessemer pig Fe in a cupola, blowing the cupola metal in a converter and then pouring the fully blown metal into molten slag, the resultant product being a sponge in every respect similar to that produced in a puddling furnace. D. S.

The applicability of coke-oven gas to the iron industry. G. BULLER. *Arch. Eisenhüttenw.* 1, 755-79(1928).—The properties, uses in the Fe industry and the types of burners for coke-oven gases are reviewed. The thermal management of coke gases is discussed. The changing of the properties of the gas with and without changing its sp. gr. is outlined in the appendix. J. BALOZIAN

Metallurgy of steel castings. A. MCCANCE. *Foundry Trade J.* 39, 465-6(1928); 40, 25-6(1929).—The main causes of the difficulties in the manuf. of steel castings are concerned with problems of contraction. The phys. actions causing these contractions,

and foundry methods of taking care of them, are given in detail. The subject is divided into 3 sections: (1) liquid contraction, *i. e.*, the contraction of the molten metal in the mold down until it reaches its freezing temp.; (2) freezing contraction, *i. e.*, the contraction which takes place when the metal passes from the liquid to the solid condition; and (3) cooling contraction, *i. e.*, the contraction which takes place during the cooling down of the casting from the solid condition at high temp. to its condition at ordinary temp.

Siemens basic steel utilizing pig iron from South African ores. G. M. NODEN. *J. South African Chem. Inst.* 11, 41-54(1928).—A brief description of the Newcastle steelworks (S. Afr.) with analyses of raw materials and finished products obtained from basic, open-hearth, steel furnaces operating on pig iron obtained from South African spathic Fe ore and on scrap obtained from the railways and mines. Tabulated details of the construction and working of 4 furnaces and of the necessary gas producers are also included.

B. C. A.

Physical chemistry of rimmed steel. J. I. CARLIN. *Blast Furnace & Steel Plant* 17, 261-2(1929).—The practice of producing rimmed steel and the phys. chemistry of the process are outlined. A summary of the points that have practical value follows: (1) the amt. of CO present in a steel before the addn. of Mn is dependent on temp. only, and is independent of C and FeO content; (2) after the Mn addn. high-C steels contain less CO than low-C steels and for this reason it is impossible to rim high-C steels; (3) the evolution of CO depends upon actual solidification of the metal; (4) C content and temp. are the most important factors in the manuf. of rimmed steel.

D. S.

Charging air by weight. H. V. CRAWFORD. General Elec. Co., Schenectady, N. Y. *Foundry* 57, 114-6, 159-62(1929).—The necessity for controlling the amt. of air supplied to a cupola melting Fe is explained. The cu. ft. of air required per min. equals 4000 times the tons of Fe melted per hr. divided by the ratio of Fe to coke, excluding the bed. The blower should be of variable capacity, so that a const. wt. of air may be delivered in spite of changes in vol. due to variations in temp. and barometric pressure. Errors as high as 46% may occur under certain conditions if a const. vol. of air is always delivered, and errors in either direction result in the Fe produced being too cold. Supplying air under const. pressure is also incorrect. A variable restriction in the air-supply pipe between blower and cupola may be controlled so that the motor operating the blower uses a const. amt. of power. With a blower and motor of suitable type, this control will result in supplying the cupola with a const. wt. of air. The design of this control system is described. The limits between which it operates are adjustable. The results of practical use of this device are given, showing satisfactory operation, and the theory of its action is also discussed.

GEO. F. COMSTOCK

Large-scale experiments for determining the economical method of operating blast stoves. MARCEL STEFFES. Tech. Hochschule, Aachen. *Arch. Eisenhüttenw.* 2, 1-10(1928).—The requirements, efficiencies and conduction and radiation losses of blast stoves used at the "Terres Rouges" mine, during their gas and blast periods, are detd. in expts. lasting up to 12 hrs.

J. BALOZIAN

Construction and operation of Kathner normalizing furnaces. C. P. MILLS. *Proc. Eng. Soc. West Penn.* 44, 305-29(1928).—The two 155-ft. Kathner normalizing furnaces of the Newton Steel Co. are described and various construction details are shown in 6 drawings and 6 photographs. The furnaces are divided into 2 main sections, the heating zone 75-ft. long, and the cooling zone 80-ft. long. The heating zone is equipped with 2 independent sets of burners; the gas burners are of the self-aspirating type and are used with high-pressure natural gas; when gas is not available oil is burned after atomization by high-pressure steam in an inducing type burner. The insulation of the furnace is a very important factor in the efficiency of its operation.

Destruction of brick by carbon monoxide. E. DIEPSCHLAG AND K. FEIST. *Blast Furnace & Steel Plant* 17, 280-2(1929); cf. following abstract.—The decompn. of brick in the lower masonry work of the blast furnace by deposited C is explained by exptl.

data to be due to the pptn. of C from CO, which action is intensified by adsorption catalysis in the presence of catalysts.

DOWNES SCHAAF

Destruction of blast-furnace building materials, particularly firebricks. E. DIEP SCHLAG AND K. FEIST. *Feuerfest* 4, 49-51, 106-8(1928); cf. preceding abstract. Methods for testing the resistance of refractories to slags are critically reviewed. Tests were made on a no. of firebricks by filling small hollows in them with weighed quantities of NaOH and KOH and firing to various temps. between 200° and 1100°, the change in the alumina : silica ratio being taken as a measure of the reaction. A considerable quantity of brick material was dissolved by NaOH at 400°, though no corrosion of the refractory was evident. Silica, particularly in the amorphous form, was attacked much more readily than alumina at this temp., but at 600-800° this difference was largely eliminated. KOH behaved similarly, but the quantity of refractory dissolved was much smaller. The melts formed at the low temp. were largely sol. in water, indicating the formation of simple silicates and aluminates, whereas those formed above 1000° took the form of insol. complexes. Between 1000° and 1015° the quantity of brick material dissolved increased considerably, but the lower reactivity of KOH was still more marked at this temp. The degree of penetration into the body of the brick depends almost entirely on the viscosity of the melt produced. It therefore does not constitute a measure of the chem. reaction which has taken place. The alumina content of the refractory has no important effect on the resistance to slag attack.

Autogenous and electric welding. R. W. MÜLLER. *Apparatebau* 41, 3-9(1929)

When the app. must be as uniform as possible autogenous welding is preferred; when high elasticity and toughness are desired elec. welding is better.

J. H. MOORE

Weld efficiency in penstock pipe using overlap welds. OREN REED. *Eng. News Record* 101, 550-2(1928).—Curves are given, based on data obtained in tests of 552 hammer-welded pipe sections, showing weld efficiency and ultimate weld strength. The variation in weld strength with plate thickness is shown graphically. A plate of $\frac{1}{4}$ to $1\frac{1}{4}$ in. in thickness will give the most consistently good welds. In general, the weld efficiency of 90% often assumed in designing penstocks is conservative, but for thin plates (less than $\frac{1}{16}$ or $\frac{1}{2}$ in.) a lower efficiency should be assumed. The data given indicate that a max. thickness of $1\frac{1}{4}$ in. or slightly greater can be used conservatively. The min. weld strength obtained was 41,200 lb. per sq. in., representing a weld efficiency of approx. 80% with plate strength of 52,000 lb. per sq. in. R. E. T.

A new butt-welding machine for 800 square millimeters iron cross-section. CONSTANTAN REDZICH. *Apparatebau* 40, 305-6(1928).—An elec. welder. J. H. M.

Carboly—a new tool material. GUY BARTLETT. General Electric Co., Schenectady, N. Y. *J. Chem. Education* 5, 1399-1405(1928).—W carbide has been joined with Co to produce the hardest cutting material yet developed in a research laboratory. It retains its cutting edge when run at a bright heat, has a Brinell hardness above 2000, a strength of 275,000 lbs./sq. in., is quite tough, withstands shock and abrasion remarkably well. Records of comparative runs in cutting high Ni-steel, alloys, glass, glazed porcelain, concrete, the faces of cast iron castings, hard castings, molded comps., genelite (an alloy of Cu, Sn and C), etc., show performance not attained by other cutting materials.

W. C. EBAUGH

Carbon-silicon relation determines suitability of iron for casting. D. G. ANDERSON AND G. R. BESSMER. Western Elec. Co., Chicago, Ill. *Foundry* 57, 106-8(1929). Small heats of cupola-melted gray Fe, mixed with Si-steel, were melted in a high-frequency induction furnace to det. the phys. properties with various C and Si contents. C contents from 3.4 to 2.3% were investigated with 1.1% Si; from 3.4 to 1.9 with 2% Si; and from 3.4 to 1.8 with 2.2% Si. Bars $1\frac{1}{2}$ in. square were cast in sand molds and tested for hardness, tensile strength and transverse strength with supports 6 in. apart. The results are tabulated, and photographs of fractures and microstructures are shown. With 1.1% Si the combined C rose sharply as the total C dropped below 3.4%, and the strength rose as it dropped below about 2.9%. With higher Si, the combined C rose as the total C fell below 2.5%. With 2% Si the max. strength was found with the lowest C, about 1.9%, but with 2.2% Si the strength was a max. at about 1.95% C. The structures became finer as the C was reduced, and the graphite particles more compact.

G. F. C.

Some causes of sponginess on the upper surfaces of iron castings. T. BUTTERWORTH. *Iron and Steel Ind.* 2, No. 2, 43-4(1928).—Sponginess is caused by dirt accumulated by the hot metal from the mold sides, by slag formed through a reaction of the metal and the mold sand, by iron oxide resulting from a reaction between the metal and the water held in the mold sand, and by gas holes formed during solidification and

originating in the soly. of O, N, CO and H in the molten metal. The question of avoidance of these defects is discussed and a number of partial solutions pointed out.

ROBERT F. MEHL

Whiteheart malleable castings. E. R. TAYLOR. *Bull. British Cast Iron Research Assn.* 1928, Oct.; *Foundry Trade J.* 39, 373(1928).—A discussion of correct testing practice for thin-walled malleable castings, and a description of the testing methods recommended by the British Engineering Standards Association for heavy engineering malleable castings.

ROBERT F. MEHL

The growth of cast iron. FRITZ WÜST AND OTTO LEIHENER. *Mitt. Kaiser-Wilhelm Inst. Eisenforsch. Düsseldorf* 10, 265–81(1928).—Thirty-one papers on the growth of cast iron are reviewed. The growth of cast iron was observed after heating specimens for various periods in a neutral atmosphere at 600° and in superheated steam at 330°. Specimens of the following composition were heated in a neutral atmosphere: 2.49 to 3.90% total C, 1.70 to 3.17% graphitic C, 0.18 to 1.03% combined C, 0.50 to 2.82% Si, 0.39 to 1.42% Mn, 0.09 to 1.87% P, 0.03 to 0.153% S. Specimens of the following composition were heated in superheated steam: 2.45 to 3.86% total C, 1.74 to 3.29% graphitic C, 0.19 to 0.91% combined C, 0.95 to 2.82% Si, 0.39 to 1.42% Mn, 0.09 to 1.87% P, 0.03 to 0.14% S. In each case specimens were selected representing three zones in the metal: (1) border, (2) between border and middle, and (3) middle. The growth in neutral atmosphere and in superheated steam within the three zones was investigated. A comparison was made of the growth of specimens normally prepared and specimens remelted in vacuum. The effect of preliminary heating in vacuum on growth in neutral atmosphere was also investigated. The data are summarized in six tables and 62 graphs. Micrographs illustrate the decomposition of cementite and the formation of graphite. It is concluded that: (1) the influence of chemical composition upon the growth of cast iron is obscured by other factors; (2) the growth in neutral atmosphere with the decomposition of cementite cannot be explained; (3) the finer the form of graphite the smaller is the amount of growth; (4) the material in the middle zone grows faster than that in the border zone; (5) the gas content of cast iron has an important influence on growth. [No conclusion is given on growth in superheated steam.]

JOHN W. W. SULLIVAN

Mechanical properties of steel castings at elevated temperatures. FRIEDRICH KÖRBER AND ANTON POMP. *Mitt. Kaiser-Wilhelm Inst. Eisenforsch. Düsseldorf* 10, 91–105(1928).—Steel castings from a Siemens-Martin furnace, a Bessemer converter, and Si and Ni castings were examd. with respect to elastic limit, tenacity, expansion, twisting strains, and resistance to pounding at temps. ranging from 20° to 500°.

HANS C. DUUS

The resistance of alloys. LOTHAR NORDHEIM. *Naturwissenschaften* 16, 1042–3 (1928). Sommerfeld's theory on metallic resistance is used for computation of the resistance of alloys. Besides the resistance of the pure metal (due to imperfection of the lattice) an addnl. resistance κ is found for alloys, which is derived from the difference in scattering power of the individual lattice units for the electron waves. Using the

Laue theory derived for x-rays for this scattering power N , finds for κ a value $\frac{(1-z)\pi\hbar}{2e^2Z^2}$

$\left(\frac{3\pi}{\pi}\right)^{1/2} \pi Q$, in which z is the fraction of second metal present, Z the no. of conduction electrons per atom, $n = N/V$ the no. of atoms per cc. The Q factor is a function of the scattering coeff. for the 2 metals; πQ can be considered as a sphere of action for the differential scattering. For low temps., where the addnl. resistance κ outweighs the ordinary one, κ as a function of z , the concn., will be a hyperbola, symmetrical when n is const. For very small concns. κ will be proportional to z . For Ag-Au data (Grüneisen) the exptl. values bear out the theory very well between $z = 0.01$ and 0.629 ; for $T = 273^\circ$ $\kappa = 0.0214$. The factor πQ is found to be $1.27 \cdot 10^{-16}$. It is also found that κ will be larger for admixts. of less closely related metals. B. J. C. VAN DER HOEVEN

The influence of grain size on magnetic qualities. II. O. v. AUWERS. *Forschungs-lab. Siemenskonzern, Berlin-Siemensstadt. Z. tech. Physik* 9, 475–8(1928).—Lately (Moos, Oertel and Scherer, *C. A.* 22, 2544) the theory has been abandoned that grain size causes the watt losses to increase proportionally. In order to study the influence of grain size and the cause of irregularities A. used electrolytic Fe of 0.02% C and variable grain size. Iron strips were annealed and stretched to 2, 4, 7, 15 and 25% elongation. These strips were heated for 40 hrs. at 870° in *vacuo* to allow recrystn. and their grain size was detd. The latter varied from 2 sq. mm. for 2% elongation to 4 sq. mm. at 4% and down to less than 0.5 sq. mm. for 15% elongation. The max. grain size was 3000

times that of the original iron heated in similar way. Complete hysteresis loops, satn., coercive force and remanence were measured on all of them. For W_A (the Watt loss) the equation $W_A = c\sqrt{N} + C$ was found to hold, N being the no. of grains per sq. mm., c and C consts. All curves show a min. at 2 to 4% elongation corresponding to the max. in the grain size. After elimination of some C and O from the Fe by 4 hrs. heating at 900° *in vacuo* the curves became more flattened out, i. e., less magnetic loss; particular improvement was shown by the samples of small grain size. Heating in H_2 gave a further improvement although the extended incandescence causes an effect by itself. It is concluded that grain size does not directly influence magnetism but causes indirect effects due to impurities (C and O) on the grain surface. The influence of gases is larger for the smaller grain size.

B. J. C. VAN DER HOEVEN

The influence of rolling temperature on stretching, spreading and work of rolling for various carbon steels in wire drawing. KURT HOPFER. *Mitt. Kaiser-Wilhelm Inst. Eisenforsch. Düsseldorf* 10, 283-99(1928).—The work of previous investigators, particularly O. Eimicke and M. Rodenbach, on the relation of rolling temperature to spreading is reviewed. The wire drawing app. used in the present investigation is illustrated by a flow sheet and by diagrams of the grooving of the roughing rolls. Rolling properties of the following steels were investigated: Thomas steel, 0.05% C, 0.40% Mn, 0.06% P; Siemens-Martin mild steel, 0.04% C, 0.37% Mn, 0.019% P; and three Siemens-Martin hard steels, 0.26% C, 0.40% C and 0.60% C, resp., with 0.20% Si, 0.71% Mn, 0.022% P. The rolling properties of these steels, when drawn down without intermediate reheating and finished, appear to be as follows: the influence of initial rolling temp. on stretching and spreading is proportionately slight; with falling temperature during rolling stretching becomes proportionately less than spreading; concerning carbon content and method of manufacturing the steel as affecting rolling, Thomas steel permits greater stretching and less spreading, whereas Siemens-Martin steel with av. carbon content of 0.45% allows less stretching and greater spreading, and the other Siemens-Martin steels are in between. Without annealing between passes, stretching decreases and spreading increases markedly with falling temp. down to 1000° for all the steels. Just under 950° stretching again increases, whereas spreading simultaneously decreases. Very probably various friction ratios between the surface of the grooves and surface of the bar and the temp. distribution within the bar decidedly influence stretching and spreading. Measurement of the work of rolling confirms the well-known dependence of rolling work on rolling temp. C content and method of manufacture influence the work of rolling in so far as Thomas and mild Siemens-Martin steels for 107-fold stretching require 75 to 87 units of work, whereas low-Si Siemens-Martin steels require 100 to 107.5 units. The max. work is required by the Siemens-Martin steel of 0.45% C, while for higher and lower C content, and at the same rolling temp., less work is required.

JOHN W. W. SULLIVAN

The hot acid etch test for steels. FRANCIS W. ROWE. *Iron and Steel Ind.* 2, No. 2, 37-40(1928).—It is pointed out that standard routine tests often fail to disclose serious defects in steel. Hot acid etch (with dil. H_2SO_4 -HCl mixt.) serves to reveal such defects. Directions on the prepn. of samples for this test and a series of photomicrographs illustrating typical defects revealed by the test are given.

R. F. M

Strength of low-carbon steels at high temperatures. R. G. BATSON. National Physical Lab. *Engineer* 146, 707-9(1929).—The materials used were tubes obtained from boiler-makers with C content ranging from 0.10 to 0.15%. For comparison a normalized steel bar, C = 0.17%, and another with C = 0.09% which had been cold-drawn and annealed at 650° for 6 hrs. were employed. "So long as strain-hardening occurs the elongation is practically general throughout the length of the test piece during a certain period. . . . When little or no strain-hardening is evidenced by the strain duration curves the elongation is found to start locally at the weakest spot, but also occurs at a decreased rate towards the ends of the test pieces." Many tables and figures are included.

D. B. DILL

The case-hardening of steels by nitrogen. ANON. *Engineer* 146, 637-8(1928).—The Fry process, in use by John Brown & Co., Ltd., is described. Machined parts of *Nitr alloy* steel are heated in a current of NH_3 at atm. pressure at 500°. The depth of nitration case is 0.2 mm. after 20 hrs. treatment and 0.8 mm. after 95 hrs. When treatment is complete the furnace is cooled quickly to 370°, and the parts are removed as soon as cool enough to handle. Brinell hardness ranges from 900 to 1100 and Shore scleroscope readings from 102 to 113. Resistance to wear is at least 10 times that of cemented and quenched steels. Max. hardness is about 0.1 mm. below the surface, tapering off gradually until a const. value is reached 0.7 mm. below the surface. Risk of peeling or spalling is eliminated. The process is only applicable to special "Nitr alloy"

steels which contain Al. Compared with cementation and quenching the advantages are: absence of distortion during nitration due to low temp. used, of deformation and of quenching cracks; parts may be nitrated in finish-machined condition; hardness is retained up to 500°; polished nitrated steel does not heat when running with Al alloys; resistance to corrosion by fresh or salt water, steam or moist air is large, and the cost of the process is small.

D. B. DILL

Nitration of steel with ammonia gas under pressure. RAYMOND H. HOBROCK. *Fuels and Furnaces* 6, 1681-2(1928).—A case depth of 0.027 inch was obtained at 875° F. after 100 hrs. at 5 mm. pressure. At 602 mm. pressure the same depth was obtained in 50 hrs. Increase in pressure (1) does not greatly change the time required for reaching the max. surface hardness, (2) tends to decrease the hardness at the surface if the treatment is continued for longer than about 25 hrs., (3) considerably increases the depth of case, (4) decreases the average hardness gradient, (5) permits the establishment of a high hardness at almost any depth depending on the pressure of the gas and the time of the treatment. An alloy intended for the establishment of a hard surface of no great depth might contain much more Al than an alloy intended for use where a deep case is required. Where high surface hardness and deep penetration are to be obtained by nitration under pressure, the amt. of Al in solid soln. in the alloy must be accurately controlled. The increase in hardness due to the nitration of alloy steels is due in part to the formation of a network of crystals of Fe nitrides and in part to the formation of slip interference particles of Al and other nitrides.

H. C. PARISH

The disclosure of the transformations of brasses containing 57.5 to 63.5% copper, by the study of mechanical properties. P. DEJEAN. *Compt. rend.* 188, 169-72(1929).—A study of the plasticity of brasses contg. 57.5 to 63.5% Cu gave very precise indications of the transformations. Cylindrical test-specimens 20 to 30 mm. in diam. and 30 to 45 mm. high were heated to the desired temps. in an elec. furnace and quickly subjected to a standard blow from a falling wt. Tests were made at various temps. from 0° to 900°; and curves show the amt. of distortion at each temp. for six alloys. An inflection is found on every curve at 480°, and another at higher temp. varying from 688° to 800° as the Cu content rose. The first transformation did not occur suddenly at 480°, but proceeded gradually from 250° or 300°. The alloys contg. least beta were more plastic when cold, and less plastic when hot than those contg. more beta. The second inflection was due to a change of alpha plus beta into beta only. This method of investigation is useful, sensitive and unexpectedly precise. G. F. C.

The study of strengthening transitions in alloys. M. HANSEN. Kaiser-Wilhelm Inst. f. Metallforschung, Berlin-Dahlem. *Naturwissenschaften* 16, 1024-6(1928).—In order to study the initial phase sepn. of highly dispersed supersatd. solid solns. H. experimented on aging of Cu-Zn alloys in the $\alpha + \beta$ range between 100° and 400°. Hardness and elec. resistance were measured at different stages of the process. Initially an increase in resistance of all the alloys appeared as expected from cond. isotherms; the first part of this rise is soon finished (1 min.); it is independent of temp.; the second part of the increase lasts longer (20 min. up to 10 hrs.) and depends on temp.; it also runs parallel with hardness changes. The total increase in resistance is at equal aging temp. larger for more supersatd. crystals and for equal compn. larger for higher aging temp. (below 300°). The subsequent decrease in resistance begins earlier for more supersatd. crystals and for higher temp. These results are shown in graphs (59 to 61% Cu, up to 80 hrs. observation). The final resistance is always higher than the initial one. The importance of the measurements in the short initial period is pointed out, the results found here are quite different from those usually assumed. B. J. C. v. d. H.

Note on the crystal structure of copper-gold alloys. CYRIL S. SMITH. Mass. Inst. of Tech. *Mining and Met.* 9, 458-9(1928).—The lattice parameters of Cu-Au alloys, quenched from 600°, were found to be as follows in A. U.; 3.731 for 24.36 atomic % Au; 3.879 for 50.41 atomic % Au; 3.976 for 74.24 atomic % Au. The structure of the alloys was not finally determined, but indications were found that Cu₃Au does not exist as such, but as a solid solution and CuAu.

HANS C. DUUS

Internal stresses as the cause of destruction of construction material. TH. HOFFMANN. *Korrosion* 4, 3(1929).—These stresses are largely due to faulty mech. and heat treatment during manuf., especially in pipes of Cu alloys.

J. H. MOORE

The internal transformations of an aluminum bronze. ALBERT ROUX AND JEAN COURNOT. *Compt. rend.* 188, 172-3(1929).—The structural transformations of a heat-treated 90-10 Cu-Al alloy were studied with x-rays, using a polished face etched with HNO₃, and exposed 6 hrs. The features of the spectrographic patterns obtained are tabulated. The annealed alloy showed only the spectrum of the α -solid soln., with face-centered cubic lattice. The spectrum of the quenched alloy showed the presence

of doubt and disagreement in previous studies. The series of alloys was prepared. Two separate series of examinations were made: (a) microscopic and (b) x-ray. The work of previous investigators is reviewed, their diagrams are presented, and the results of this investigation compared with them. The (a) series showed: (1) Max. soly. of Sn in α br is 15% at room temp., increases to 16% at 520° and falls to 13% at 800°. (2) The boundary of the β field is a smooth curve running from 22% Sn at 800° to 26.75% Sn at 520°; its slope increases when the temp. drops below 600°. The Sn-rich boundary of the β field is a smooth curve starting at 26% Sn at 750°, reaching a max. Sn content of 28.5% at 610–630° and then decreasing to the eutectoid, 26.75% Sn at 520°. An allotropic change was found in the β field. (3) The β - γ field was definitely located with the upper horizontal at 750° from 26 to 27.5% Sn and the lower at 540° from

and solid soln. extending from 26 to 27.5% Sn at room temp., formed directly at 540°. It is not Cu_3Sn . (6) The 38.36% alloy (η) is Cu_3Sn and occurs as such at room temp. (7) Both β - δ and δ - γ fields were found. (8) A new section of the phase diagram was found on the Sn side of δ , existing from 580 to 610° in alloys of 33 to 34.5% Sn. The (b) series of tests showed: (1) α is a solid soln. with face-centered cubic lattice, lattice parameter varying from 3.579 A. U. for pure Cu to 3.691 A. U. at 15% Sn. (2) β is a solid soln. with body-centered cubic lattice; $a_0 = 2.964$ A. U. at 26.5% Sn. No change occurs on passing 580°. (3) δ is a solid soln. (4) γ is unstable. (5) η is pure Cu_3Sn , its lattice is close-packed hexagonal of axial ratio 1.576, $a_0 = 2.74$ A. U., $c = 4.32$ A. U. The experimental procedure is given, results are tabulated, and 81 photomicrographs given and described. A. BUTT

The structure of copper-tin alloys. W. BRONIEWSKI AND B. HACKIEWICZ. *Compt. rend.* 187, 651–4 (1928).—The δ phase of Cu-Sn alloys whose composition is variously given as 40–50 at. % Sn has not been definitely identified because of the uncertainty due to the extreme slowness of establishment of equilibrium. More complete equilibrium than ever before was obtained by annealing the alloys up to 24% Sn *in vacuo* for 330 hrs. at 620°, 670 hrs. at 400°; those from 25 to 40 at. % Sn were annealed consecutively 1000 hrs. at 400° and 6000 hrs. at 200°; the alloys with more than 40 at. % Sn were annealed 7000 hrs. at 200°. Two curves are reproduced which clearly show the compounds Cu_3Sn and Cu_2Sn (previously established) and the new Cu_3Sn_2 corresponding to the δ phase. The formation of δ upon annealing is very slow. The structure of Cu-Sn alloys is much simpler at ordinary temperature than at the solidus. The solid soln. of Sn in Cu reaches 1 at. %, whereas that of Cu in Sn seems to be less than 1%. Cu_3Sn_2 dissolves about 1 at. % Cu and 5 of Sn; Cu_2Sn appears to dissolve about 1% of the metals, although Cu_3Sn only forms mixtures. The great importance of allowing sufficient time for the establishment of equilibria in indirect methods of studying alloy structure is stressed. Also in *Rev. metal* 25, 671–84 (1928); 26, 20–8 (1929). ALBERT THOMAS FELLOWS

Lead-tin-cadmium as a substitute for lead-tin wiping solder. EARLE E. SCHUMACHER AND EDWARD J. BASCH. Bell Telephone Labs., New York, N. Y. *Ind. Eng. Chem.* 21, 16–19 (1929).—In making wiping solder economy will result if Cd (costing about as much as Sn) can be substituted for a part of the Sn, provided it enables a large proportion of Pb to be used in the alloy. Pb-Sn-Cd alloys were therefore prepared and their properties compared with those of standard solder (62% Pb-38% Sn), studied and phase diagrams, solidification ranges, composition changes when heated above their melting points, rates of oxidation, tensile strength, porosity and wiping characteristics, etc. The addition of Cd made possible the use of higher percentages of Pb in satisfactory solders, giving solders cheaper than corresponding Pb-Sn solders. A solder containing 68% Pb, 23% Sn and 9% Cd is satisfactory as a substitute for standard 62% Pb, 38% Sn solder, so far as lab. tests go. Life tests in actual practice are still lacking. W. C. HUBAUGH

The destructive action of molten zinc, at and above zincing (galvanizing) temperatures, upon metals and alloys. WALLACE G. IMHOFF. *Am. Metal Market* 35, 2nd section, 10–13 (1928).—A discussion of the metal Zn, its abundance and importance as a metal for protective coatings. H. C. PARISH

Patching cast aluminum. STYRIE. *Apparatebau* 40, 30A-7 (1928).—A good corrosion-resisting solder consists of 70–5%

Zn and 1-1.5% Mn. It melts from 580 to 640° and should be used at 650°. A less resistant solder consists of 10-12% Al, 15-20% Zn, 20-30% Cd and 30-40% Pb; it melts at 200-400°. A good flux consists of 5 parts powdered borax, 5 parts Na_2CO_3 and 1 part S, well mixed.

J. H. MOORE

Plastic extension of aluminum crystals at high temperatures. KEIJI YAMAGUCHI AND SAKUICHI TOGINO. *Bull. Inst. Phys. Chem. Research Tokyo* 7, 646-58(1928); *Abstracts* 1, 58-9.—Test pieces of a single crystal of Al were extended slowly or rapidly at 525-600°. The change of the direction of tension referred to the crystal axis of the test piece was ascertained from Laue photographs taken before and after the extension had taken place. Where the tension is uniform, the spots are not elongated. Stripes are visible similar to slip bands, in the direction of intersection between the slip-plane and the surface. This direction agrees with that expected from the Laue photograph taken before extension, under the assumption that the strain is a simple shear. Examn. of these stripes under high magnification shows that they are different from ordinary slip bands; they consist of wavy uneven stripes; as far as can be resolved under the microscope, the deformation is a simple shear about every point. When the crystal is extended at a definite temp., with a definite tension, and with a definite velocity, the shear stress always increases as the test piece extends, but it was considered to flow under a steady shear stress, because the increase is less than that of an isotropic material, and because the test piece extended at a high temp. did not increase in hardness. A mechanism is proposed to explain this fact: "Since at high temp., atomic vibration due to heat energy is great, the probability is large that the resistance to shear along a particular slip plane is lowered. In such a case, though the slip takes place in that plane, it is self-stopping since the probability for the continuance of this state must be small. This probability is considered to become nearly zero at ordinary temp. If the slip takes place in this case, the crystal must be strained. The mechanism of self stopping of the slip at a high temp. and at an ordinary temp. differs utterly."

ALBERT L. HENNE

The preparation and mechanical properties of duralumin. MASAHARU GOTO, SINICHI FUKATU, SADA O HORIGUCHI AND TENJI NAGAI. *Report of the Aeronautical Research Inst., Tokyo Imperial University*, 3, 273-403(1928). (Two-page abstract in German.)—Because of the difference in sp. gr. of Cu and Al, homogeneous products can be obtained only by special stirring during mixing. The molds must be heated to 100-150° before casting. The pouring temp. should be 1%-2% higher than that of the melt. The cast metal can be rolled at 450 ± 20°. The greatest tenacity is obtained by quenching at 520° and annealing at 100°. Blisters appear to be caused by the interaction of gases attacking the sheet. The compn. of duralumin is Cu 3-4, Mg 0.5-0.75, and Mn 0-0.5%. Fe improves the pouring and rolling qualities, but is harmful in respect to the other properties. Large quantities of Si are harmful but 1% improves the mech. properties. Zn up to 3% is advantageous. Ag improves the malleability of the poured metal, but not that of the rolled metal. Alkalies in any quantity are very harmful. The tensile strength decreases at 200° and is very small at 500°. The malleability increases up to 400° and then falls. A new hypothesis of the embrittlement of Al alloys is developed.

Platinum and other metals. ALLGEMEINE ELEKTRO-METALLURGISCHE GESELLSCHAFT M. B. H. Fr. 644,051, Nov. 16, 1927. Ores, gang and products from the metallurgical industry are heated to redness with reducing agents such as C and cooled with avoidance of any oxidation. Pb and other metals such as Ni and Co may be extd. by a magnetic sepn.

Furnace for the reduction of ores. SVEN EKLUND. Fr. 644,294, Oct. 13, 1927.

Steel manufacture in a Siemens-Martin furnace. F. SIEMENS A.-G., R. DURRER, F. C. SIEMENS and A. SPRENGER. Brit. 293,326, Dec. 24, 1926. A layer of gases practically free from H is formed, at the end of the fining process, between the bath and the

heating medium in order to prevent access to the bath of any oxidizing medium which may be present in the furnace. Blast-furnace gas may be used or the gas from a tapping producer which works without steam and in which a coal poor in gases, coke or semi-coke is used. Various structural details of the furnace are described. Cf. C. A. 23, 1102.

Blast-furnace construction. JAMES P. DOVEL. Fr. 644,537, Sept. 7, 1927.

Cupola-furnace construction. FREIER GRUNDER EISEN- UND METALLWERKE GES. Brit. 294,027, July 21, 1927.

Manufacture of basic-converter steel. G. BERGER and L. BERGER. Belg. 347,592, Jan. 31, 1928. The converter comprises a retort of the usual type with a basic refractory lining. Mounted on, and connected with the duct through which the blast is brought to the converter, is a hopper capable of contg. at least the amt. of CaCO_3 required for the charge.

Steel. SOCIÉTÉ ANON. DES HAUTS FOURNEAUX, FORGES ET ACIÉRIES DE POMPEY. Fr. 643,924, Apr. 16, 1927. A mild steel contains Cu 0.2 to 0.5, and Ni 0.2 to 0.4%. An example is given contg. Fe 98.78, C 0.05, Si 0.05, Mn 0.4, P 0.04, S 0.03, Cu 0.4, Ni 0.25%.

Apparatus for "batch tempering" steel articles, etc. JAMES M. SCHOONMAKER, JR., and LASZLO M. STREMPER. U. S. 1,702,524, Feb. 19.

Malleable cast iron. CHRISTIAN É. KLUIJTMANS. Fr. 643,930, April 16, 1927. Belg. 347,522, Jan. 31, 1928. See Brit. 288,980 (C. A. 23, 592).

Coating cast iron with lead. OSKAR SPENGLER. U. S. 1,703,019, Feb. 19. Pb is melted onto the surface of cast iron after the latter has been preliminarily treated with a Cu salt such as CuSO_4 , a Sn salt such as SnCl_2 , and a Zn halide such as ZnCl_2 .

Sponge iron. H. G. FLODIN. Brit. 293,868, July 14, 1927. In producing metal sponge such as that of iron, briquets comprising crushed ore, C and a binder are fed from the briquetting app. through a drier and preheater into a reducing chamber where reduction is effected by heat produced by combustion of charcoal with air in an annular chamber surrounding the reducing chamber. CO from the reduction chamber is also utilized to assist in the heating. Various structural features are described.

Case-hardening iron or steel articles. MORRIS MOTORS (1926), LTD., J. A. RICHARDSON and R. A. SMART. Brit. 293,531, May 21, 1927. Case-hardening or malleabilizing of iron or steel articles is effected by passing an elec. current through carbonaceous material in which they are embedded in a rotary receptacle.

Case-hardening and quenching compound. F. HEYMANS and F. COMPDAER. Belg. 346,883, Jan. 31, 1928. The product consists of a mixt. of Na_2CO_3 , NH_3 , BaCO_3 , prussiate, NaCl, borax and chrome yellow.

Alloys. L. LEVA. Belg. 346,963, Jan. 31, 1928. Abrasion-resisting alloys contain Fe 97.94–95.54, C 0.80–1.30, Si 0.3–1, Mn 0.60–1.80, S and P < 0.18% and optionally 0.5–3% Cr. The alloys are obtained in an elec. furnace.

Alloys for electric resistance heating. GENERAL ELECTRIC CO., LTD., and C. J. SMITHELLS. Brit. 293,740, April 7, 1927. An alloy of Ni 70, Cr 20 and W or Mo 10% or a similar alloy is used for resistance heating or otherwise where good resistance to oxidation at high temps. is required. Impurities are avoided.

Alloys of nickel and chromium, etc. GENERAL ELECTRIC CO., LTD., and C. J. SMITHELLS. Brit. 293,727, April 7, 1927. Alloys contg. Ni and Cr, with or without Mo or W, are prepd. by heating the pure metals in an atm. such as H which prevents introduction of impurities. Details of the process and of prepg. the sep. metal powders are given. Brit. 293,728 relates to the use of an alloy of Ni 70 and Cr 30% or similar alloys in making distn. vessels or oxidation resisting stay rods of boilers, etc.

Iron alloys containing molybdenum. A. KISSOCK (to Climax Molybdenum Co.). Brit. 293,860, July 15, 1927. Mo is added to Fe or other metals or their alloys by adding a Mo compd. such as Ca molybdate to a molten bath or slag on such a bath of which at least, one constituent has a greater affinity for O than Mo has. The addn. may be made during reduction or melting of the iron. Alloys of Mo with Ni, Al, Cu and Si are mentioned.

Magnesium-aluminum-silicon alloys. I. G. FARBENIND. A.-G. Brit. 293,359, July 4, 1927. See Fr. 639,256 (C. A. 23, 594).

Steel alloys. E. H. DOPPEL. Brit. 293,764, July 11, 1927. Elements such as Si, Mn, Ni, Cr, W, Co, V and Ti are introduced into steel in combination with Al (preferably in an alloy contg. at least 9% Al).

Tungsten alloy. HENRY L. COLES and JOSEPH G. DONALDSON (to Guardian Metals Co.). U. S. 1,702,765, Feb. 19. An alloy which is heat-resistant and is suitable for use in safe and vault walls comprises W 86 or less, Ni approx. 14 and C 2–5 parts. U. S.

1,702,766 specifies metal plates suitable for similar purposes formed of an alloy contg. W over 70, Ni 10 and Cu 14% and surrounded and united with a metal such as a casing of Cu having a high heat cond. Cf. C. A. 23, 1104.

Amalgams. DEUTSCHE GOLD- UND SILBER-SCHNEIDANSTALT, VORM. ROESSLER. Fr. 644,412, Nov. 23, 1927. In the prepn. of Hg amalgams particularly for *dentistry*, the Hg is used in the form of a paste contg. a part of the solid with which it is to be amalgamated.

Sulfuric acid pickling baths. V. BERTLEFF. Brit. 293,701, July 9, 1927. To prep. an inhibiting agent for pickling baths, coal tar is heated with not more than an equal quantity of concd. H_2SO_4 until the product is completely sol. in water. The product thus obtained may be neutralized with milk of lime, filtered and concd. $Ba(OH)_2$ may be used as a treating agent to obtain purified sulfonic acids. Various waste products from sulfonation processes also may be used as starting materials.

Apparatus for heat treatment of ball races or other metal articles. FRANK TWYMAN (to Adam Hilger). U. S. 1,702,985, Feb. 19.

Die-casting machine. INJECTA A.-G. Ger. 470,483, Dec. 11, 1926.

Sherardization. SOC. D'ELECTRICITÉ ET DE MÉCANIQUE. Belg. 347,487, Jan. 31, 1928. The surface of the object is coated with Zn powder and a volatile binder, e. g., a nitrocellulose soln., and the object is then heated in presence of air.

Protecting metals during melting from oxidation and absorption of gases. V. N. ZWIBEL. Russ. 5080, Apr. 30, 1928. The melted metal is protected by adding to the usual flux heavy hydrocarbons, such as pitch, tar, etc., in solid form or in powder, whereby a reducing atm. is obtained above the metal.

Protecting cables, pipes or other metal articles from corrosion. CHEMIE-PRODUKTE GES. Brit. 293,835, July 13, 1927. A wrapping is used formed of strips of fabric or paper coated with a compn. comprising residues from petroleum distn., soft bitumen and fillers such as china clay or talc, $BaSO_4$, slate or asbestos. Various details and proportions are given.

Arc-welding electrodes. E. M. F. ELECTRIC CO. PROPRIETARY, LTD. Brit. 293,283, June 28, 1927. Structural features are specified relating to electrodes comprising assembled wires and which may have reënforcing wires of high-C steel, Ni or Ni-Cr alloy which is melted simultaneously with the electrode core.

Soldering composition. N. N. KVSHEV. Russ. 5238, April 30, 1928. A mixt. of powd. Pb 2 parts and Sn 1 part is mixed with a soln. of 2 parts of rosin in 1 part of gasoline.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Biochemical studies on pityrol. I. Introduction to the biochemistry of pityrol. SHIGERU KOMATSU. *Mem. Coll. Sci. Kyoto Imp. Univ. Ser. A*, 11, 481-95 (1928). The tar which is obtained on the destructive distn. of rice bran is said to possess curative properties in cases of eczema; this tar has been called *pityrol*. Bran from the rice named "Shinriki" and grown near Osaka was subjected to dry distn. in an Al retort; a colorless oil begins to distil with some water at about 200° , the color of the distillate becoming darker with rise in temp.; the largest fraction b. $350-400^\circ$ and the distn. is ended at 450° ; the yields were 24% tar, 28% coke, 36% aq. liquor, 12% gas, the tar is sol. in EtOH, Me_2CO or PhH; about 15% of the tar is volatile with steam and consists of 4% basic, 29% acidic and 67% neutral compds.; 85% of the tar is non-volatile with steam and consists of 3% basic, 29% acidic and 68% neutral compds. The hydrocarbons in pityrol are similar to those in Russian or Japanese petroleum and low temp. coal tar, appearing mostly as members of the polymethylene series with a mol. wt. equiv. to $C_{20}H_{40}$ and with also a few aromatic hydrocarbons. The non-volatile neutral fraction, b_{10} above 250° , when applied to the inner surface of a rabbit's ears produces first malignant epithelioma which finally terminates in true cancer; this production of cancer is never observed with pityrol. Previous workers have shown that true cancer can be produced by an unknown and unstable compd. which occurs in the fraction of coal tar b. $250-500^\circ$ and which is removed by purification of the tar. The cancer-producing principle of the tars, therefore, seems to bear the same relationship to the tar as a vitamin does to a food material. The difficulty often encountered in isolating an enzyme or a vitamin in a pure state gives support to the belief that the behavior, particularly the biol. actions of a compd., would not be the same in every respect when it is employed in assocn. with other substances with which it occurs in

ture. **II. Distillation of rice bran.** SHINZABURO FUJITA. *Ibid* 497-503.—Rice bran was heated to 80° for 1 hr. to destroy the enzymes; it was divided into 2 parts (A and B) and 1 part (B) was extd. with petr. ether; analysis of A gave C 46.2, H 7.4, N 2.4, S 1.5, H₂O 14.7, ash 9.3, fat 22.4, protein 12.9, cellulose 11.4, pentosan 8.7, reducing sugar 1.3, sucrose 10.6%. The acid and I nos. of the fat were 160 and 118, sp. Analysis of B gave C 39.9, H 6, N 3, S 2, H₂O 14.1, ash 12, fat 0.7, protein 16.5, cellulose 14.6, pentosan 11.1, reducing sugar 1.5, sucrose 13.6%. Dry distn. of A and of B gave, resp., tar 24, 15; coke 28, 31; aq. liquor 36, 40; gas 12, 14%; 13% of the tar from A is volatile with steam, having d_4^{25} 0.967, and 87% is non-volatile with steam, having d_4^{25} 0.871; similarly from B, 17% volatile, d_4^{25} 0.981, 83% non-volatile, d_4^{25} 0.919; the aq. liquor A, d. 1.021 with 22% org. matter; aq. liquor B, d. 1.035 with 19% org. matter; the compn. of the gas from A and from B was, resp., 22%, 31% bases; 25.4%, 17.4% C_nH_{2n}; 0.4%, 0.4% C₂H₄; 2%, 3% C_nH_{2n+2}; 17.3%, 20.6% CO, 31.8%, 31.6% CO₂. **III. Neutral constituents of pityrol.** SABURO SAKAMI. *Ibid* 505 15.—The tar obtained on destructive distn. of rice bran when steam distd. gave 12% of volatile material; the volatile (A) and non-volatile (B) portions were sep'd into neutral, acidic and basic fractions by treating with 7% NaOH and 10% H₂SO₄, successively. Analysis of the neutral fraction gave b. p. up to 150°, paraffin 5, aromatic 13, unsatd. hydrocarbons 79%; b. 150-80°, paraffin 9, aromatic 5, unsatd. hydrocarbons 86%; b. 180-210°, paraffin 13, unsatd. hydrocarbons 87%; b. 210-40°, paraffin 14, unsatd. hydrocarbons 86%; b. 240-70°, paraffin 24, unsatd. hydrocarbons 76%. The following were isolated and identified: octane, nonane, decane, undecane, dodecane, tridecane, tetradecane and pentadecane; the principal parts of the neutral oil are the C₁₀, C₁₁, C₁₂ and C₁₃ paraffins. The unsatd. hydrocarbons were sep'd. by treatment with concd. H₂SO₄ and then distd. *in vacuo*; hydrocarbons of the mol. formulas C₁₆H₃₂, C₁₈H₃₆, C₂₀H₄₀, C₂₄H₄₈ and C₂₈H₅₆ were identified; it is believed that these are polymers formed by the action of H₂SO₄ on the compds. C_nH_{2n} or C_nH_{2n+2}, and that C₉H₁₈, C₁₀H₁₈, C₁₂H₂₀ and C₁₄H₂₄ are the main constituents of the volatile neutral oil. The neutral non-volatile part of pityrol is composed mostly of hydrocarbons of the polymethylene series C₁₀, C₁₁, C₁₄ and C₁₅. **IV. Acidic constituents of pityrol.** BUNKICHI MASUMOTO. *Ibid* 517-9.—The acidic constituents from 20 lbs. of pityrol were isolated by extn. with 5% NaOH and gave 90 g.; it is a dark brown oil with phenolic odor, partly sol. in H₂O. After drying with Na₂SO₄ 80 g. were fractionally distd. at 19 mm. and gave 35.1 g. b. 30-120°, 32.1 g. b. 120-50°, 12.8 g. b. above 150°. Further treatment with Me₂SO₄ and fractional distn. gave evidence of a compd. C₁₀H₁₈OMe. **V. Basic constituents of pityrol.** SHIGEKIYO SUZUKI. *Ibid* 521-32.—The basic fraction by extn. with dil. H₂SO₄ is a dark brown viscous liquid with a pyridine odor; it was purified by steam distn. giving 460 g. insol. in H₂O and 190 g. sol. in H₂O. These 2 fractions were further sep'd. by fractional distn. and conversion to salts with picric acid, HCl and HgCl₂. The following were isolated and identified in the basic fractions: 2- and 3-methyl-, 2,4- and 2,6-dimethyl-, and 2,4,6-trimethylpyridine, aniline and quinoline, there is also some evidence for the presence of 2,5-dimethyl- and tetramethylpyridine and an unknown base, 47% C and 3.5% H. **VI. Distillation of palmitic acid.** SEIICHI SHOYAMA. *Ibid* 533-42.—Distn. of Na palmitate in an Al retort gave 70% tar, 24% coke and 6% gas and loss. The gas is 11.8% CO, 12.2% CO₂, 1.7% C₂H₄, 27.4% C_nH_{2n+2} + H₂. On steam distn. of the tar 45% is volatile and consists of a trace of acids, 25% satd. hydrocarbons, 23% unsatd. hydrocarbons; the non-volatile part is 3% palmitone, 8% satd. hydrocarbons and 47% unsatd. hydrocarbons. **VII. Distillation of oleic acid.** HIROSHI OGATA. *Ibid* 543-7.—Distn. of Na oleate gave tar 65, coke 17, gas 18% and loss. The tar has d_4^{25} 0.794, n_D^{25} 1.445, I no. 142, and on steam distn. 47% is volatile, b. 41-260°, I no. 158, d₄ 0.766, n_D^{25} 1.427; the non-volatile portion has d_4^{25} 0.828, n_D^{25} 1.457 and I no. 105. The main constituents of the tar are hydrocarbons of the olefin series with the formulas C₈H₁₆, C₉H₁₈, C₁₅H₃₀, C₁₆H₃₂ and C₁₇H₃₄. **VIII. Distillation of sucrose.** YOSHINORI HIDAKA. *Ibid* 549-51.—Distn. of sucrose from an Fe retort between 240° and 610° gave 25% tar and aq. liquor, 45% coke and 20 l. of gas. The compn. of the tar and aq. liquor was H₂O 75, neutral substances 4.5, acidic substances 1.5 and humus 8.5%; another analysis gave hydroxymethylfurfural 1, furfural 2.6, methylfurfural 2.5, HCO₂H 8.1 and levulinic acid 0.4%. **N. A. LANGE**
Glycol. J. ALTENBURG. Charlottenburg. *Seifensieder Ztg.* 55, 393-4, 403-4 (1928). Prep'n. and properties of glycol. **P. ESCHER**
Ethylene glycol as a glycerol substitute. KARL BRAUN. *Am. Perfumer* 23, 513-4 (1928).—The sugar fermentation process for glycerol is reviewed. (CH₂OH)₂

is made in America from the gases of kerosene by increased pressure and low temp. By treatment with Cl_2 ethylene chloride is formed and from this by hydrolysis with NaOH glycol is obtained. It has a lower f. p. than glycerol and the cost is less.

E. SCHERUBEL.

Molecular compounds of organic iodides with sulfur. HEINRICH RHEINBOLDT AND KURT SCHNEIDER. Univ. Bonn. *J. prakt. Chem.* 120, 238-48(1929).—P. p. diagrams are given for a no. of org. iodides with S. The following eutectics were observed, the % being that of S: MeI , 42 and 69%, 85° and 91°; the compd. $\text{MeI} \cdot 3\text{S}_8$ (66.2% S) is indicated. C_2I_4 , 54 and 68%, 95.5° and 101°; the compd. $\text{C}_2\text{I}_4 \cdot 4\text{S}_8$ (65.9% S) is indicated. $\text{C}_3\text{H}_7\text{I}$, 28%, 65°; $\text{C}_2\text{H}_5\text{I}$, 29%, 54°; $\text{C}_4\text{I}_4\text{NO}_2$, 35%, 80°; C_3I_3 , 29%, 48°; C_2Br_4 , 13%, 44°; *p*- $\text{C}_6\text{H}_4\text{I}_2$, 58.5%, 91°; Ph_2I_2 , 94%, 117°. CHI_3 and AsBr_3 do not form an addn. compd. No eutectic was observed with S and CH_2I_2 , CHBr_3 or C_6I_6 .

C. J. WEST

Purification of methyl fluoride. Quantitative gas analysis by high-dispersion infra-red spectroscopy. WILLARD H. BENNETT. *J. Am. Chem. Soc.* 51, 377-81 (1929).—A method is described for the prepn. of MeF from KF and KCH_3SO_3 . A spectroscopic examn. in the infra-red was made on purified and unpurified samples of the gaseous MeF and from these data a quant. detn. was made of the amount of MeF and of Me_2O present.

WALLACE R. BRODE

Organic arsenic derivatives. Action of alkalis on diethylchloroarsine. E. GRYSZKIEWICZ-TROCHIMOWSKI, M. BUCZWIŃSKI AND J. KWAPISZEWSKI. *Roczniki Chem.* 8, 423-31(431 French)(1928).—By the action of alkalis on Et_2AsCl , diethylarsine oxide (I), AsEt_3 (II), (mercuric chloride, m. 163-4°), and EtAsO (III) are obtained. II and III correspond to the decompn. products of I: $(\text{Et}_2\text{As})_2\text{O} = \text{Et}_3\text{As} + \text{EtAsO}$, a reaction analogous to the pinacol rearrangement. I has an irritating odor resembling that of $(\text{Me}_3\text{As})_2\text{O}$, oxidizes in the air forming $\text{Et}_2\text{AsO}_2\text{H}$, crystallizes with 2HgCl_2 , b. 8-9, 90.5-3.5°, b. 760 225-30°, d_4^{20} 1.2989.

J. KUČERA

Aldehydes and acetylenecarbinols. II. Dimethyloctenaldehyde, *tert*-butylmethylacrolein and experiments with the acetylenecarbinol prepared from acetophenone. H. RUPF AND LOUISA GIESLER. Basel. *Helv. Chim. Acta* 11, 656-69(1928), cf. C. A. 22, 2928.—*Isohexyl Me ketone* (I) was purified to remove unsatd. ketones by adding 4% KMnO_4 with stirring at 0° until the color was no longer discharged, steam distg., sepg. and drying; it b. 162-3°, *semicarbazone*, m. 151°. *Isohexyl*(α -methyl-ethinyl)carbinol (II), prepd. in 66-70% yield by adding 36 g. powd. NaNH_2 to 100 g. I in Et_2O cooled with ice, then satg. with C_2H_4 , stoppered, allowed to stand overnight, poured on ice, washed with HCl , extd. with Et_2O , dried with MgSO_4 , the Et_2O removed, shaken with NaHSO_4 , redissolved in Et_2O , washed with Na_2CO_3 , dried and fractionated under 10 mm., b. 80-2°; it forms a Na salt with concd. NaOH , a Ag salt with alc- NH_3 - AgNO_3 and a benzoate, b. 64° (from 10 g. II, 8 g. $\text{C}_6\text{H}_5\text{N}$ and 4 g. BzCl). When II was boiled for 0.5 hr. with 6-7 parts HCO_2H , poured on ice, extd. with Et_2O , washed with Na_2CO_3 , dried over MgSO_4 , fractionated under 11 mm., the fraction b. 82-91° converted to *semicarbazones* which were fractionally recrystd. from EtOH , it gave a slightly sol. *product A*, m. 170°, and a sol. *product B*, m. 122°, which are the *semicarbazones* of β,β -dimethyl- β -octenaldehyde (III) and of a structural isomer of unknown constitution, resp. (88% total yield of aldehydes of which 90% is A and 10% is B); these *semicarbazones* on steam distn. with $\text{H}_2\text{C}_2\text{O}_4$ gave the aldehydes; III is a colorless oil with an odor like citral, b. 94°; the *isomer* is an oil with the same odor, b. 98-100°, because of the low yields no derivs. of the *isomer* were prepd.; III forms an oily *oxime* with an odor like caraway, b. 131-2°, and an unstable cryst. *phenylhydrazone*. Oxidation of III in CCl_4 with O_3 or in Na_2CO_3 with 4% KMnO_4 gave isocaproic and acetic acids; reduction of III (25 g.) with H (4.3 l.) and Ni (50 g.) in dil. EtOH gave β,β -dimethylcaprylaldehyde (22 g.), b. 78-9°; *semicarbazone*, m. 97°; *oxime*, colorless oil, b. 131-2°. When methyl-*tert*-butylethinylcarbinol (IV) (cf. C. A. 18, 2682) was boiled for 3 hrs. with 8 parts of HCO_2H , it gave 18% of β -methyl- β -*tert*-butylacrolein (V), $\text{Me}_3\text{CCMe}:\text{CHCHO}$ and the *isomeric aldehyde* (?) (in the ratio of 2:1, resp.) which were sepd. as *semicarbazones*, m. 193° and 148-9°, resp.; V is a colorless oil with an odor like coumarin, easily oxidized in air, n_D^{20} 1.46718, d_4^{20} 0.8822 (*oxime*, b. 131°); the *isomeric aldehyde*, b. 150°; when IV is treated with H_2SO_4 , the proportion of this *isomer* is increased. *Pinacol* was prepd. like II in 10% yield and satg. with C_2H_4 ; it b. 102-3°, m. 20°, it was also prepd. with C_2H_4 but by adding 8 g. Na to 40 g. BzMe in 160 g. cold Et_2O and then satg. with C_2H_4 but *pinacol* is obtained as a by-product (cf. Ciamician and Silber, *Ber.* 33, 2912(1900));

when boiled for 10 mins. with HCO_2H it gave a very poor yield of *phenylmethylacrolein*, PhCMe:CHCHO , b_{12} 122–3°, an oil with an odor like PhCH:CHCHO ; *semicarbazone*, m . 201°. Attempts to prep. similar compds. with BzEt were abandoned because of the very low yields. The reactions as given above are as follows:

N. A. LANGE

Aldehydes from acetylenecarbinols. III. Preparation of two dimethylhexenaldehydes. H. RUPE, A. WIRZ AND P. LOTTER. *Anstalt für organ. Chemie, Basel. Helv. Chim. Acta* 11, 965–71(1928); cf. *C. A.* 22, 2928 and preceding abstract.—Mesityl oxide when reduced at room temp. and atm. pressure with Ni as catalyst gave iso-BuCOMe (I) (90% yield). To 250 g. I in 300 cc. abs. EtOH was added 125 g. powd. NaNH_2 . The mixt. was stirred 3–4 hrs., cooled to 0° and pure C_2H_2 passed in. The product (80–90% yield) was methylisobutylethynylcarbinol (II), b_{80} 85–7°, peppermint-like odor. When 50 g. II was heated 40–60 mins. with 400 g. 70% HCO_2H , it gave a mixt. of 2 aldehydes in a yield of 60–70% of the quantity of II used. One aldehyde gave no compd. with NaHSO_3 , and was β,δ -dimethyl- β -hexenaldehyde (III), peppermint-like odor, pale yellow, b_{80} 94–6°. The other, of which only a small quantity was obtained, formed a compd. with NaHSO_3 and was β,δ -dimethyl- α -hexenaldehyde (IV), coumarin-like odor, b_{80} 102–12°. IV polymerized readily but could be stabilized by a small quantity of hydroquinone. III in Na_2CO_3 with 4% KMnO_4 was converted into AcOH and iso- PrCO_2H ; IV on oxidation in the same way gave I and a small quantity of a substance of unknown constitution, m . 88–9°. On reduction with Ni as catalyst, both III and IV gave β,δ -dimethylcaproaldehyde, b_{80} 93–4°; *semicarbazone*, m . 121–2°.

LOUISE KELLEY

Pinacols and pinacolins. E. PACE. *Atti accad. Lincei* 8, 309–14(1928).—In a previous paper it was shown that γ -diketones when treated with Grignard reagents give tertiary glycols which are very readily converted to heterocyclic derivs. of tetrahydrofuran tetrahydropyrrole and tetrahydrothiophene. The same reaction has been applied to α - and β -diketones. The β -compds. do not react, but the α -derivs. give pinacols and pinacolins. The following were prepd. Ac_2 with MeMgBr added drop by drop gives $[\text{Me}_2\text{C}(\text{OH})]_2$ when the product is decompd. with ice-water; crystd. from Et_2O , m . 38°, b . 175°; it recryst. also from water with 6 H_2O , m . 47°. With EtMgBr the corresponding $[\text{MeEtC}(\text{OH})]_2$, m . 51°, b . 216°, is formed. With PrMgBr , $[\text{MePrC}(\text{OH})]_2$, m . 62°, b . 228–30°, is formed. The above pinacols when treated with H_2SO_4 ($1/4$) and subsequently steam distd. give the corresponding pinacolins according to the scheme $[\text{MeRC}(\text{OH})]_2 \rightarrow \text{RCOCrMe}_2 + \text{H}_2\text{O}$. A. W. C.

Effects of the spatial position of substituted groups on acidic strength. DONALD H. HEY. Univ. Coll., Swansea. *J. Chem. Soc.* 1928, 2321–3.—Rule, Hay and Paul (*C. A.* 22, 3157) support their conclusions regarding the effect of terminal alkyloxy and CO_2H groups upon rotatory power by citing parallel phenomena in the influence of substituents on the acidity of geometrically isomeric acids. The dissociation consts. of the 2 crotonic acids and of other acids of the same type indicate that the spatial proximity of a Me or Cl group to the CO_2H group in every case increases the acidic strength and that the change thus produced is in the same direction as that produced by the CO_2H group in fumaric and maleic acids. Thus the observation of R., H. and P. is invalid. The behavior of substituted BzOH is also discussed; it is possible to observe a close analogy between the effect of *o*-substitution and *cis*-substitution. C. J. W.

Effect of the spatial position of substituent groups on acidic strength. BERNHARD FLÜRSCHHEIM. *J. Chem. Soc.* 1928, 3039–40.—F. claims the arguments of Hey (preceding abstr.) are the same as he used in earlier publications. C. J. WEST

Cyclic acetals. I. RUDOLF DWORZAK AND THERESIA M. LASCH. Univ. Wien. *Monatsh.* 51, 59–72(1929).— $\text{MeEtC}(\text{CH}_2\text{OH})_2$ (5 g.), 5 g. 40% HCHO and 5 g. concd. HCl , satd. with HCl at room temp. and then heated, give 30% of the formal, $\text{MeEtC}(\text{CH}_2\text{O})_2\text{CH}_2$, b . 150–2°; *acetal*, b . 156–60° (30% yield). The formal of dimethyltrimethyleneglycol, b . 124–7° (28% yield); *isobutyral*, b . 159–61° (67% yield), intense camphor-like odor; *enanthal*, b . 234–9° (78% yield). *Isobutyral* of 2-methylpentane-1,3-diol, b_{12} 69–70° (69% yield); of *butane-1,3-diol*, b_{10} 42.5–3° (63% yield), camphor odor; of 2,4-dimethylpentane-2,4-diol, b_{11} 67–73° (25% yield); of 2,3-dimethylbutane-2,3-diol, b_{11} 59° (68% yield); of 3,4-dimethylhexane-3,4-diol, b_{10} 81–3° (66% yield). Definite products could not be isolated from pentane-1,4-diol, octane-1,8-diol, nonane-1,9-diol and decane-1,10-diol.

C. J. WEST

Remarks on the communication of J. Böeseken and B. B. C. Felix: Configuration of pentaerythritol. II. The optically active dipyrucic acid-pentaerythritols. J. KENNER. Municipal Coll. Tech., Manchester. *Ber.* 61B, 2470-1(1928).—B. and F. (*C. A.* 23, 99) believe that the resolution of dipyrucic acid-pentaerythritol (I) into optically active components proves the tetrahedral configuration of pentaerythritol (II), at least in alc. soln., and that it is unnecessary to assume pyramidal, along with tetrahedral, mols. as long as no cyclic *cis-trans*-isomeric dialdehydic or diketonic ethers have been isolated. According to Weissenberg the pyramidal configuration of II is conditioned by the endeavor of the mol. to maintain the equivalence of the 4 CH_2OH groups. In a pyramidal mol. of I, then, the CH_2O groups 1 and 3 would be equiv. to each other but different from groups 2 and 4, which are likewise equiv. to each other. This also holds for the hypothetical compd. III but in this the equivalence would be attained by a tetrahedral configuration and such a configuration would therefore be required for III according to the W. view. From this standpoint, *cis-trans*-isomerism would be expected for I. Although it seems justifiable to assume a conversion of a possibly existing pyramidal into a tetrahedral configuration before rather than after the condensation of the II with AcCO_2H and therefore the existence of tetrahedral mols. of II may be deduced from B. and F.'s expts., it is also possible that these constitute only a small % of the total no. The W. principle can therefore not be tested by chem. methods such as that of B. and F. Apparently this can be done only by the röntgenographic and other phys. methods applied to II and similar compds. of the type Ca_4 but unfortunately there is at present no agreement as to the interpretation of results obtained in this way. K. emphasizes that this is not a defense of or attack on either configuration but only intended to point out an interesting limitation of the chem. methods.

C. A. R

Reduction of the secondary hydroxyl group in ricinoleic acid. FRITZ SIGMUND AND FRITZ HAAS. Univ. Wien. *Monatsh.* 50, 357-68(1928).—Reduction of Et ricinoleate by Na and AmOH yields essentially oleyl alc. (I) and only a trace of the expected glycol (μ -hydroxyoleyl alc.). I b_{10} 206-7° and yields an Ac deriv., b_{12} 215-8°; reduction gives stearyl alc., b_{12} 197-201°, m. 58.5°, whose Ac deriv. b_{12} 205-8°, m. 34.5°. The reduction of the HO group not vicinal to the double bond is anomalous but was found also to occur in the reduction of ricinoleic acid (II) or its derivs. by H in the presence of Löw's Pt black. Com. II contains only about 85% of free acid; it was purified by heating with NaOH and sepn. of the Ba salt. Reduction of II in AcOH yields stearic acid or a mixt. of II and stearic acid when hydrogenation is incomplete. Similarly the Me ester (III) of II yields Me stearate under all conditions tried. The action of AcCl on III yields the Ac deriv. of 84% purity, which could not be further purified by repeated fractionation; reduction gives an impure Me acetoxystearate, b_{17} 239-44° (cor.), from which λ -hydroxystearic acid was obtained by hydrolysis, this acid resisted catalytic reduction and in the reduction of II the HO group must, therefore, be reduced before the double bond.

C. J. WEST

Some β -disubstituted chlorohydrin acids. ERIK TROELL. Univ. Lund. *Ber.* 61B, 2497-503(1928).— α -Hydroxy- β -chloro- β -methylbutyric (I), α -hydroxy- β -chloro- β -phenylbutyric (II) and α -hydroxy- β -chloro- β , β -diphenylpropionic acid (III) were prepd by addn. of HCl to the corresponding β -disubstituted glycidic acids. NaNH_2 is a much more satisfactory condensing agent than NaOEt . The decompn. of I in alk. soln. is not a simple bimol. reaction. All attempts to prep. salts of these acids failed; instead of the Na, Cu or Ag salt of the acid are obtained the metal chloride and an evil smelling product which reacts neutral but gradually uses up alkali. In the condensation of Ph_2CO with $\text{ClCH}_2\text{CO}_2\text{Et}$ there is obtained after distn. an ester, b_{12} 202° (IV), thought by Pointet to be Et diphenylglycidate (V) but which is really the ketonic ester $\text{Ph}_2\text{CHCOCO}_2\text{Et}$ formed by rearrangement from the glycidate during the distn.; only when distn. at a high temp. is avoided can the glycidate be obtained. I, m. 80.6-1.3°, easily sol. in but rapidly decompd. by H_2O , stable in dry form and can be kept *in vacuo* over H_2SO_4 . The velocity of its decompn. in H_2O cannot be followed with alkalis, as it does not give a sharp end point, but it is stable in concd. HNO_3 and its decompn. by alkalis can be followed by titrating the liberated Cl by the Volhard method. The

velocity const. increases with decreasing initial concn. (k at 0°, 4.4, 6.7, 8.1 with initial concns. of 0.00585, 0.00309, 0.00158, resp.); in buffered solns. k is 0.0119 and 0.0118 at pH 7.0 and 5.4, resp. II, m. 82° (decompn.), rapidly decomps. in the air. The Na salt corresponding to IV, treated in the usual way with dry HCl did not give a chlorohydrin acid but β,β -diphenylpyruvic acid, m. 116° (VI), very stable in H_2O (in which its soly. is 1.11 g. per l.), dissociation const. 1.3×10^{-2} , gives Ph_2CHCO_2H when heated at 150°, forms a phenylhydrazone, m. 189° (decompn.). After repeated distn. *in vacuo* IV showed d. 1.1344, n_D 1.45638. If, instead of distg. the condensation product of $ClCH_2CO_2Et$ and Ph_2CO , it is treated directly with $NaOEt$ (after removing the Et_2O under atm. pressure and the $ClCH_2CO_2Et$ *in vacuo*), the sirupy acid obtained from the resulting salt is different from VI, yields an aldehyde on distn. and with HCl in Et_2O gives a sirupy acid contg. Cl which is probably III. C. A. R.

Synthesis of ζ -aminoheptylic acid. R. TAKAMOTO. Tokyo Imp. Univ. *J. Pharm. Soc. Japan* 48, 872-6(1928).— ϵ -Bromoamylamine (which was obtained by catalytic reduction of furylethylamine and subsequent bromination) and $BzCl$ gave benzoyl-bromoamylamine(I), m. 54-5°. I, $CH_2(CO_2Et)_2$ and Na gave Ethyl benzoylamino-amylmalonate which on boiling with 4 vols. of concd. HCl gave ζ -aminoheptylic acid-HCl(II), m. 97-9°. II and moist Ag_2O gave the free acid (III), m. 186-7°. Heating of III in vacuum at 180-90°, gave the lactam. It is claimed that the above method is less expensive and simpler than the older ones. NAO UYEI

Physicochemical investigation of amino acids. GAKUJI TAKAHASHI AND TOKUZO YAGINUMA. Nihon Daigaku, Tokio. *Proc. Imp. Acad.* 4, 561-4(1928).— l -Leucine-HCl forms a monohydrate. The Et ester of l -leucine-HCl exists in 2 isomeric forms, 1 m. 119° and a 2nd, which seps. from a hot satd. $EtOH$ -HCl soln. and appears to be metastable at room temp., easily changing to the stable form, m. 119°. The following data are given as curves: b. p. curve for the Et ester; soly. of l -leucine in H_2O (cryohydric point, 0.2° and 2.21% leucine); data for the system: l -leucine-HCl- H_2O at 15° and 30°; optical activity and dispersion of solns. of l -leucine in HCl- H_2O . C. J. WEST

Catalytic racemization of amino acids and peptides. MAX BERGMANN AND LEONIDAS ZORVAS. Kaiser Wilhelm-Inst. fur Lederforschung, Dresden. *Biochem. Z.* 203, 280-92(1928).—In the acetylation of amino acids 3 phases are distinguished. In the 1st phase, when not more than 1 mol. Ac_2O is used, there is an acetylation on the N, with retention of the optical activity. In the 2nd phase, on further reaction with a mol. of Ac_2O , the amino acid becomes completely racemized but not altered in compn. With much larger amts. of the anhydride (several mols.) the acetylated racemized amino acid loses water. The 2nd phase proceeds with unusual velocity, the Ac_2O acting catalytically. The catalysis can also be produced with CO_2 or Bz_2O . S. M.

The amino acid methionine; constitution and synthesis. GEORGE BARGER AND FREDERICK PHILIP COYNE. Univ. Edinburgh. *Biochem. J.* 22, 1417-25(1928).—In 1923 Mueller isolated from caseinogen a new amino acid, $C_5H_{11}O_2NS$ (see C. A. 17, 2400). By applying Kirpal and Buhn's method for the detn. of MeS groups (see C. A. 8, 2163), B. and C. found one to be present. This result restricted the possible formulas to derivs. of butyric and isobutyric acids. Since the cleavage products of proteins are α -amino acids, only 4 formulas remained: α -, β -, and γ -methylthiolbutyric acids (I III) and methylthiolisobutyric acid (IV). $EtC(NH_2)(SMe)CO_2H$ (I), $MeCH(SMe)CH(NH_2)CO_2H$ (II), $MeSCH_2CH_2CH(NH_2)CO_2H$ (III), $MeSCH_2CMe(NH_2)CO_2H$ (IV). III seemed the most probable since it was related to cheirolin, $MeSOCH_2CH_2CH_2N:C:S$, the sulfone of a mustard oil. B. and C. synthesised III (the *dl* substance) and found it to be identical with Mueller's acid, except for optical activity (see C. A. 23, 170). III is γ -methylthiol- α -aminobutyric acid and B. and C. suggest the name "methionine" for it. *Prepn. of III*: 2700 g. casein was hydrolyzed with H_2SO_4 and the filtrate, neutralized with $NaOH$, was divided into halves. To one was added 1350 g. $HgSO_4$ in 7% H_2SO_4 . The ppt. (A) was filtered after 24 hrs. The filtrate was half-neutralized, causing a ppt. (B) 4-5 times as bulky as (A). By neutralizing the filtrate to Congo red a still larger ppt. (C) was obtained. The 2nd half of the hydrolyzate was treated with only $1/3$ of the reagent added to this 1st half; the resulting ppt. (D) was filtered off, an additional third of the reagent was added, giving ppt. (E), and to its filtrate the 3rd instalment of the reagent, giving (F). All 6 ppts. were washed twice by decantation, and twice by filtration, and extd. 5 times, with 1 l. of 2% $Ba(OH)_2$ each time. The 5 combined exts. were freed from $Ba(OH)_2$ by H_2SO_4 from Hg by H_2S , and the filtrate and washings were evapd. to 500 cc. A boiling satd. soln. of 20-50 g. $HgCl_2$ was added. The $HgCl_2$ ppt. was freed from Hg by H_2S , the filtrate was evapd. *in vacuo*, dissolved in the min. quantity of boiling water and mixed with 5-10 cc. pyridine (to remove HCl) and 3 vols. boiling alc. The following

yields were obtained: (A) 2 g. histidine with traces of **III**; (B) 0.05 g. **III**; (C) was lost by accident; (D), (E) and (F), resp., 0.5, 0.5 and 0.6 g. **III**. *Synthesis of III by Strecker's method*: $\text{MeSCH}_2\text{CH}_2\text{CH}(\text{OEt})_2$, (**V**) was prepd. by passing 2 mols. MeSH into 1 mol. alc. NaOEt and dropping 1 mol. $\text{ClCH}_2\text{CH}_2\text{CH}(\text{OEt})_2$ into it. The MeSH was prepd. by hydrolysis of $\text{MeSC}(\text{:NH})\text{NH}_2$. $\text{MeSCH}_2\text{CH}_2\text{CHO}$, (**VI**) was obtained by boiling **V** for 0.5 hr. with 2 vols. water contg. 1–2 cc. dil. HCl . The aldehyde sep'd. on cooling and was extd. with ether. $\text{MeSCH}_2\text{CH}_2\text{CH}(\text{NH}_2)\text{CN}$, (**VII**) was prepd. by adding 1 equiv. of KCN in the min. quantity of water to a well-cooled mixt. of **VI** in ether and 1 equiv. of concd. aq. NH_4Cl ; 2–3 g. NH_4Cl was then added and the mixt. shaken for 6 hrs. The Et_2O layer was sep'd. and the aq. layer extd. with ether. The total ether ext. was dried over Na_2SO_4 and dry HCl passed into the well cooled soln. **III** was obtained from **VII** by pouring off the ether, adding 2 vols. concd. HCl and boiling for 2 hrs. The HCl was removed as much as possible by vacuum distn. and the residue dissolved in the min. amt. of boiling water. Ten cc. pyridine was added to remove free HCl . The addn. of 3 vols. boiling alc. caused the amino acid to sep. in clusters of narrow platelets. Recrystd. from alc., it m. 281° without decompn. Analysis 5.91 mg. gave 0.551 mg. N (micro-Kjeldahl); 9.38 mg. gave 14.5 mg. BaSO_4 (micro-Carius). Found: 9.3% N, 21.3% S; calcd., 9.4% N and 21.5% S. B. H.

Polypeptide-*N*-carboxylic acids. F. WESSELY, E. KEMM AND J. MAYER. Univ. Wien. *Z. physiol. Chem.* 180, 64–74 (1929); cf. C. A. 22, 1757.—*N*- CO_2H acids of dipeptides are unstable, losing CO_2 when the free acids are liberated from their salts. Esters of such acids, however, yield stable products when sapond. This is because of a rearrangement which occurs, yielding isomers of the *N*- CO_2H acids in which the NH_2 groups of the 2 component amino acids are joined through CO . The products may be regarded as carbonylbispeptides or sym. disubstituted ureas. The rearrangement is believed to occur *via* ring closure to an intermediate hydantoin with loss of alc., the hydantoin then opening up by hydrolysis with formation of the carbonylbispeptide. According to this view the urea linkage is formed before rupture of the peptide linkage occurs. Direct evidence by isolation of the intermediate hydantoin has not yet been obtained, but indirect evidence is now at hand from a study of the *N*-carbalkoxyl derivs. of isomeric pairs of dipeptides. *E. g.*, the intermediate hydantoin from the *N*- CO_2Me derivs. of alanylglycine and glycylalanine should be isomeric, but both of them should yield the same carbonylbispeptide on hydrolysis. Two such pairs of isomeric dipeptides were converted into their *N*- CO_2Me derivs. and subjected to the sapon. treatment. Each pair actually yielded one and the same di- CO_2H acid—the expected carbonylbispeptide—in conformity to the theory. *Carbomethoxyalanylglycine*, a difficultly crystallizable oil, was prepd. in the usual way from *dl*-alanylglycine and ClCO_2Me , and without purification it was sapond. by warming with *N* NaOH . By evapn. of the reaction mixt. and extn. with EtOH , *alaninecarbonylglycine*, m. $180\text{--}2^\circ$, was isolated and identified; its *di*-*Me* ester, m. $105\text{--}6^\circ$, was prepd. by treatment with CH_2N_2 . *Carbomethoxyglycylalanine*, m. $169\text{--}70^\circ$, was prepd. in the same way from the isomeric dipeptide. Sapon. yielded the same carbonylbispeptide. Both products gave the same m. p., as did also their *Me* esters, and mixed m. ps. showed no depression. *Et carbomethoxyglycyl- β -aminobutyrate* and its isomer *carbomethoxy- β -aminobutyrylglycine Et ester* were prepd. by the method of Leuchs and sapond. by *N* NaOH . The reaction mixts. were acidified, evapd. to dryness and esterified by 3% alc. HCl . The products obtained in several sep. expts. melted $97.5\text{--}8.0^\circ$, 96.5° , $102\text{--}3^\circ$, $103\text{--}4^\circ$. Despite these discrepancies, mixed m. ps. showed no depression, thus establishing the identity of the sapon. products from the 2 dipeptides. Analysis agreed with that calcd. for *glycinecarbonyl- β -aminobutyric acid di-Et ester*. With NH_3 in the β -position the intermediate heterocyclic compd. would here be a hydouracil instead of a hydantoin, but the reaction is entirely analogous. *Carbomethoxyphenylalanylphenylalanine*, m. 179.5° , was prepd. from the dipeptide and ClCO_2Me and sapond. as above. Here the reaction is more complicated since there are 2 possible forms of the resulting carbonylbis[phenylalanine]. Both forms, m. 203° and 176° , resp., were isolated from the reaction mixt., and their *Et* esters, m. $142\text{--}3^\circ$ and 138° , resp. A. W. DEX

The behavior of polypeptides containing *dl*- α -aminovaleric acid towards normal alkali, erepsin and trypsin-kinase. EMIL ABDERHALDEN, PETER SAH AND ERNST SCHWAB. Univ. Halle. *Fermentforschung* 10, 264–73 (1928).—One dipeptide and 2 tripeptides contg. *dl*-valine, and several of their derivs. were prepd. *dl*- α -Bromoisovaleryl-glycine, m. $136\text{--}8^\circ$, was obtained from *dl*- $\text{Me}_2\text{CHCHBrCOBr}$ and glycine, and by treatment with 25% NH_4OH was converted into *dl*-valyl-glycine, m. 248° ; *Cu salt*, amorphous, by boiling the dipeptide soln. with freshly pptd. CuO ; *PhNCO deriv.*, m. $188\text{--}90^\circ$; β - $\text{C}_{10}\text{H}_7\text{SO}_2$ deriv., m. 195° . *dl*- α -Bromoisovaleryl-glycyl-glycine, m. $145\text{--}6^\circ$,

was obtained from $dl\text{-Me}_2\text{CHCHBrCOBr}$ and glycine anhydride in N NaOH, and aminated to $dl\text{-valylglycylglycine}$, m. 240° ; Cu salt, violet-blue crystals; Bz deriv., m. 155° ; PhNCO deriv., m. $216\text{--}7^\circ$; $\beta\text{-C}_{10}\text{H}_7\text{SO}_2$ deriv., m. 190° . $dl\text{-Valylglycine}$ and ClCH_2COCl were coupled in the usual way to $chloroacetyl\text{-}dl\text{-valylglycine}$, m. 141° , and the product aminated to $glycyl\text{-}dl\text{-valylglycine}$, m. 239° ; PhNCO deriv., m. $197\text{--}8^\circ$; $\beta\text{-C}_{10}\text{H}_7\text{SO}_2$ deriv., m. 148° . Only those peptides in which the glycyl component carries the free NH_2 are hydrolyzed by N NaOH at 37° . Thus, $dl\text{-valylglycine}$ remains unaltered, while the isomeric $glycyl\text{-}dl\text{-valine}$ slowly undergoes hydrolysis. Likewise, $dl\text{-valylglycylglycine}$ is resistant, while $glycyl\text{-}dl\text{-valylglycine}$ breaks up into glycine and $valylglycine$. All of the PhNCO derivs. undergo hydrolysis. In contrast to the $\beta\text{-C}_{10}\text{H}_7\text{SO}_2$ derivs. of other peptides, which are less readily attacked by alkali than the free peptides, those of all 3 valyl peptides are hydrolyzed. The PhNCO derivs. described here conform to the general rule that such derivs. are more rapidly hydrolyzed than the unsubstituted peptides. Erepsin hydrolyzes all 3 of the above peptides, but all 3 are resistant to trypsin-kinase. On the other hand, the PhNCO deriv. of $valylglycylglycine$ is resistant to erepsin but not to trypsin-kinase. A. W. Dox

The behavior of $dl\text{-}\alpha,\epsilon\text{-dileucyl}\text{-}dl\text{-lysine}$ towards normal sodium hydroxide, erepsin and trypsin-kinase. EMIL ABDERHALDEN AND HANS SICKEL. Univ. Halle. *Fermentforschung* 10, 302-4(1928); cf. *C. A.* 23, 1114.— $dl\text{-Lysine}$ was prepd. from benzoyl-piperidine by the v. Braun synthesis (*C. A.* 3, 1273), and converted into 70% $\alpha,\epsilon\text{-di-[}dl\text{-}\alpha\text{-bromoisocaproyl]-}dl\text{-lysine}$, amorphous scales, by treatment of the di-HCl salt with $dl\text{-Me}_2\text{CHCH}_2\text{CHBrCOCl}$ and purification of the product by pptg. the Et_2O soln. with petroleum ether. The Br deriv. was aminated by heating 2 hrs. under pressure with 10 parts of 25% NH_4OH , yielding $\alpha,\epsilon\text{-di-[}dl\text{-leucyl]-}dl\text{-lysine}$, and the $\text{NH}_4\text{-Br}$ removed by the $\text{Ag}_2\text{SO}_4\text{-Ba(OH)}_2$ procedure. The tripeptide is amorphous and decomp. 160° (foaming). The aq. soln. is alk. to litmus, gives ppts. with picric and phosphotungstic acids and shows positive biuret and ninhydrin reactions. It is hydrolyzed by N NaOH, also by erepsin but more rapidly by trypsin-kinase. A. W. D.

Behavior of polypeptides constructed of $d\text{-alanine}$ towards normal alkali, erepsin and trypsin-kinase. EMIL ABDERHALDEN AND JUAN J. DELGADO Y MIER. Univ. Halle. *Fermentforschung* 10, 251-5(1928).—Polypeptides built up from a single amino acid, with the exception of glycine, have thus far proved to be more resistant to hydrolysis by alkali than those contg. 2 or more different amino acids. The di- and tripeptide of d alanine were prepd. and examd. with respect to resistance towards hydrolyzing agents. $d\text{-Alanyl-}d\text{-alanine}$ has been previously described; PhNCO deriv., m. 176° ; $\beta\text{-C}_{10}\text{H}_7\text{SO}_2$ deriv., m. $158\text{--}9^\circ$. $d\text{-}\alpha\text{-Bromopropionyl-}d\text{-alanyl-}d\text{-alanine}$, m. 148° , was obtained by alk. hydrolysis of $d\text{-alanine}$ anhydride and coupling with MeCHBrCOCl in the usual way. By treatment of this with 25% NH_4OH it was aminated to $d\text{-alanyl-}d\text{-alanyl-}d\text{-alanine}$, amorphous, m. 245° , $[\alpha]_D^{20} -15.1^\circ$. Both di- and tripeptide are hydrolyzed by N alkali at 37° , the latter more readily than the former. The PhNCO deriv. of the dipeptide is completely hydrolyzed in 3 hrs. to $d\text{-alanine}$ and the PhNCO deriv. of $d\text{-alanine}$, but the $\beta\text{-C}_{10}\text{H}_7\text{SO}_2$ deriv. is quite resistant. Erepsin hydrolyzes both peptides, the di- more readily than the tripeptide. Neither one is attacked by trypsin-kinase. A. W. Dox

The relation of chemical structure to the rate of hydrolysis of peptides. IV. Enzyme hydrolysis of dipeptides. P. A. LEVENE, LAWRENCE W. BASS AND ROBERT E. STEIGER. Rockefeller Inst. *J. Biol. Chem.* 81, 221-30(1929); cf. *C. A.* 21, 100.—In the hydrolysis of dipeptides by erepsin the reaction follows the course of a monomol reaction. In concns. of the substrate from 0.025 to 0.50 M the rate of hydrolysis is approx. proportional to the concn. of the enzyme. When a peptide composed of glycine and a $dl\text{-acid}$ is compared with one composed of glycine and a naturally occurring amino acid in regard to their rates of hydrolysis, the concns. of the 2 substances should be in the ratio of 2:1; if 1 peptide is composed of 2 $dl\text{-acids}$ and the other of 2 optically active naturally occurring acids, the ratio should be 4:1. The rates of hydrolysis of $glycylglycine$, $glycyl\text{-}d\text{-valine}$, and $glycyl\text{-}l\text{-valine}$ are of the same order of magnitude at the same concn. With peptides contg. $d\text{-alanine}$ an exceptional behavior (not explainable) was observed: hydrolysis of $d\text{-alanyl-}d\text{-alanine}$ occurred most rapidly; next in order was $dl\text{-alanylglycine}$; the lowest rate was found for $glycyl\text{-}dl\text{-alanine}$. Peptides contg. 1 amino acid enantiomorphous to that occurring naturally are not hydrolyzed by erepsin; on digestion of $dl\text{-alanylglycine}$ and similarly constituted peptides, the form contg. the amino acid enantiomorphous to that occurring naturally remains intact. $Glycyl\text{-}d\text{-isovaline}$ is not hydrolyzed by erepsin even though isovaline is configurationally related to the amino acids occurring in proteins. $Glycyl\text{-}l\text{-valine}$, $[\alpha]_D^{25} 20.3^\circ$ in H_2O .

A. P. LOTHROP

The alkaline decomposition of cystine. JAMES C. ANDREWS. Univ. of Penna. School of Med. *J. Biol. Chem.* 80, 191-210(1928).—The alk. decompn. of cystine is a complicated process involving a rapid decrease in the optical activity of the cystine, formation of sulfide ion and of cysteine and evolution of NH_3 . One of the most outstanding features of the decompn. is the marked and sp. effect of Pb on these various reactions. The rate of loss of cystine and of deaminization is greatly increased by the presence of amts. of Pb sufficient to ppt. all the S as PbS . While the initial formation of cystine is very little affected by the presence of Pb, the latter causes its decompn. to set in more rapidly than otherwise would be the case. This specificity of Pb in cystine chemistry leads to interesting speculations as to any possible connection with its very sp. properties as a poison. The speed of racemization of cystine in alkali is much greater than the speed of decompn. The optical configuration of the cystine is without influence on the rate of loss of NH_3 . Most of the reactions were carried out at approx. room temp. as heating so accelerates the reactions as to make an individual scrutiny of them impossible.

A. P. LOTHROP

Stereochemical studies. XVII. Optical resolution and configuration. BROR HOLMBERG. *Z. physik. Chem., Abt. A.*, 137, 18-28(1928); cf. *C. A.* 22, 386.—The principle of Winther, which states that 2 acids which are pptd. by the same base must possess analogous configurations, has been established by H. in the case of 22 racemic acids with active EtPhNH . Contradictory data were found, however, which limit the value of this principle as a means of detg. configuration. **XVIII. Nitromalic acid.** *Ber.* 61B, 1885-93(1928).—Optically inactive nitromalic acid (I) and the *l*(-)-acid (II) were prepd. from the corresponding malic acids and $\text{H}_2\text{SO}_4\text{-HNO}_3$. Attempts to isolate an active form from I by treatment with EtPhNH were not successful. II, m. 114-5° (decompn.), $[\alpha]_D -38.6^\circ$ (in acetone), -36.8° (in alc), -42.8° (AcOEt), -23.1° (water); acid Na salt in water -26.7° , neutral Na salt -10.5° . Nitration of Et malate gives the *Et ester* of II, d_4^{20} 1.202, $[\alpha]_D^{20} -30.55^\circ$. Reduction of II with Na-Hg or H_2S gives *l*(-)-malic acid. Analogous to the behavior of monohalogen succinic acid, II with alkali gives fumaric acid. (-)-Bromosuccinic acid (III) with AgOAc gives II. According to H.'s picture of org. cations with positively ladened

C (see *C. A.* 20, 3281; 22, 386) $\begin{array}{c} \text{a} \\ \diagup \\ \text{b} \text{---} \text{C}^+ \\ \diagdown \\ \text{c} \end{array} + \bar{\text{O}}.\text{NO}_2 = \begin{array}{c} \text{a} \\ \diagup \\ \text{b} \text{---} \text{C}.\text{O}.\text{NO}_2 \\ \diagdown \\ \text{c} \end{array}$ III belongs

to the *l*-series. If the nitrate ion is formulated as $\bar{\text{NO}}_3$ or $[\text{NO}_3]^-$, the relation may be different, depending on reaction distances (see *C. A.* 20, 1600). **XIX. The diazotization of aspartic acid and its ethyl ester.** *Ibid* 1893-1905.—In view of the various contradictory results on the diazotization of aspartic acid (I) and its Et ester, H. has repeated these expts. under various conditions, and showed in what manner the optical activity of the resulting malic acid (II) was influenced by the acid content of the diazotization mixt. The effects of various concns. of HNO_3 , and various acids were studied. In each case the $\text{UO}_2\text{-}[\alpha]_D$ of the resulting II was detd. With sufficient H-ion concn. *l*-II predominates, while with lower concns. there is formed some (+) or racemic II. Excess NaNO_2 causes the formation of β -nitronitrosopropionic acid. NaNO_2 with HNO_3 gives a small amount of *l*(-)-nitromalic acid; NaCl , (-)-chlorosuccinic acid. Diazotization of the Et ester of I gives inactive II. With increase of the mineral acid, however, the resulting II becomes weakly *d*-rotary. Diazotization of this ester in the presence of neutral salts gives corresponding esters of nitro-, chloro-, and bromosuccinic acid. The various results are discussed in the light of H.'s theory. The hydroxy-, nitroxy-, and halogensuccinic acids formed in the diazotization of I and its Et ester are of the same configuration. The (+)-halogensuccinic acid and the (-)-hydroxy acid, as well as natural I or the (+)-form, possess *l*-configuration

FREDERICK C. HAHN

Chemical constitution and rotatory power. III. S. BERLINGOZZI. *Atti accad. Lincei* 7, 925-9(1928); cf. *C. A.* 22, 1758.—In order to arrive ultimately at a relation between the chem. constitution and rotatory power, the rotation of acyl derivs. $\text{H}_2\text{NCOCH}_2\text{CH}(\text{NHR})\text{CO}_2\text{H}$ ($\text{R} = \text{Acyl}$) of *l*-asparagine were measured: Below are given, in order, the acyl group R, $[\text{M}]_D^{20}$, K and the m. p. of the compd.: anisoyl, 40.2, 0.0032, —; cuminoyl, 43.9, 0.0050, 158-9°; *p*-toluyl, 43.2, 0.0051, 192°; *p*-chlorobenzoyl, 41.2, 0.0093, 181°; *p*-nitrobenzoyl, 30.8, 0.0040, —; *m*-toluyl, 49.0, 0.0051, 162°; *m*-nitrobenzoyl, 35.3, 0.0345, —; *o*-chlorobenzoyl, 20.5, 0.1320, 171°; *o*-bromobenzoyl, 13.4, 0.1450, 163°; *p*-toluenesulfonyl, 19.5, 2.100, —; 1-nitro-2-toluene-4-sulfonyl-, 85.6, —, 174°.

A. W. CONTIERI

Derivative of *dl*-asparagine. S. BERLINGOZZI. *Atti accad. Lincei* 7, 1037-40

(1928).—It is known that when an equimol. mixt. of *d*- and *l*-asparagine is evapd the *dl*-form is not obtained but rather an intimate mixt. of the 2 forms which can be sepd. The same result obtains when most acyl derivs. are used. However, mixt. of the *d* and *l*-forms of *m*-nitrobenzoylasparagine and *d*- and *l*-1-nitro-2-toluene-4-sulfonylasparagine give the *dl*-product; the former m. 191° (the *d*- and *l*-forms m. 176°), and the latter m. 190° (*d*- and *l*-forms m. 174°).

A. W. CONTIERI

Centenary of Wöhler's synthesis of urea (1828–1928). FREDERICK G. HOPKINS. Biochem. Lab., Cambridge. *Biochem. J.* 22, 1341–8(1928).—Critical review of the significance of Wöhler's discovery.

BENJAMIN HARROW
